2. The value-altering effect is either (a) an increase in the reinforcing effectiveness of some stimulus, in which case the MO is an establishing operation (EO); or (b) a decrease in reinforcing effectiveness, in which case the MO is an abolishing operation (AO).
3. The behavior-altering effect is either (a) an increase in the current frequency of behavior that has been reinforced by some stimulus, called an *evocative effect*; or (b) a decrease in the current frequency of behavior that has been reinforced by some stimulus, called an *abative effect*.
4. The value-altering effect of an MO changes the potency of reinforcers (or punishers) to increase and maintain (or decrease and eliminate) behavior
5. The behavior-altering effect is a change in frequency due to the organism's behavior contacting reinforcement or punishment. This change occurs only *after* the consequence has been obtained.
6. The value-altering and behavior-altering effects of an MO occur simultaneously but are considered independent in the sense that one does not derive from the other. However, once behavior contacts reinforcement, these two effects may not be discernible.
7. The behavior-altering effect of the MO can directly increase or decrease the frequency of behavior. It can also indirectly affect the evocative or abative strength of relevant discriminative stimuli.
8. The value-altering effect of the MO can directly alter the reinforcing (or punishing) effectiveness of the relevant consequence. It can also indirectly alter the reinforcing (or punishing) effectiveness of any (conditioned) stimulus correlated with the relevant consequence.
9. S^Ds and MOs alter the current frequency of behavior (behavior-altering effect).

10. Reinforcers, punishers, and response occurrence without consequence alter the future frequency of behavior (function-altering effect).

Distinguishing Between MOs and S^Ds

11. An S^D controls a type of behavior because it has been related to the *differential availability* of an effective reinforcer for that type of behavior. This means that the relevant consequence has been available in the presence of, and unavailable in the absence of, the stimulus. Most variables that qualify as motivating operations fail to meet this second S^D requirement because in the absence of the variable, there is no MO for the relevant reinforcer, and thus no reinforcer unavailability.

12. A useful contrast is that S^Ds are related to the differential availability of a currently effective form of reinforcement for a particular type of behavior, whereas MOs are related to the differential reinforcing effectiveness of a particular event.

13. In nontechnical terms, an S^D tells you that something you want is available; an MO makes you want something.

Unconditioned Motivating Operations (UMOs)

14. For all organisms there are events, operations, and stimulus conditions with unconditioned *value-altering* effects. In other words, these MOs establish or abolish the value of stimuli as reinforcers in the absence of prior learning.

15. The main UMOs for humans are those related to deprivation and satiation with respect to food, water, oxygen, activity, and sleep; and those related to sexual reinforcement, comfortable temperature conditions, and painful stimulation. For each variable, there are two MOs, one with an establishing operation (EO) and one with an abolishing operation (AO). Also, each variable has an evocative effect and an abative effect. Thus food deprivation is an EO and has evocative effects on relevant behavior, and food ingestion is an AO and has abative effects on relevant behavior.

MOs for Punishment

16. MOs alter (increase or decrease) the punishing effectiveness of a stimulus, as well as the frequency (evoke or abate) of behaviors that have been punished by that stimulus.

17. An EO related to punishment would have a punisher-establishing effect and an abative effect.

18. An AO related to punishment would have a punisher-abolishing effect and an evocative effect, in that behaviors that have been punished would occur again (assuming that a reinforcer contingency for the previously punished behavior is intact).

19. In the case of conditioned punishers that were established by having been paired with the removal (or reduced availability) of reinforcers (i.e., negative punishment), their effectiveness as conditioned punishers will depend on the same MOs that establish the value of the reinforcers that were removed.

20. Social disapproval, time-out from reinforcement, and response cost are stimulus conditions that usually function as punishment because they are related to a reduction in the availability of some kinds of reinforcers. The MOs for those forms of punishment are the MOs for the reinforcers that are being made less available.

Multiple Effects of MOs

21. Most environmental events have more than one effect upon behavior.

22. Events that function as UMOs will typically have behavior-altering effects on the current frequency of a type of behavior and, when presented as consequences, will have function-altering effects on the future frequency of behavior that immediately preceded their onset.

23. Events that have MO evocative effects, such as painful stimulation, will also function as punishment for the response immediately preceding the onset of the event.

24. Events that have MO abolishing effects, such as food consumption, may have reinforcing effects when presented as consequences for behavior.

Conditioned Motivating Operations (CMOs)

25. Motivating variables that alter the reinforcing effectiveness of other stimuli, objects, or events, but only as a result of the organism's learning history, are called *conditioned motivating operations* (CMOs). As with the UMOs, they also alter the momentary frequency of all behavior that has been reinforced (or punished) by those other events.

26. The surrogate CMO (CMO-S) is a stimulus that acquires its MO effectiveness by being paired with another MO, and has the same value-altering and behavior-altering effects as the MO with which it was paired.

27. The CMO-S appears to play a role in the development of behaviors that do not seem to make much sense, such as seeing a restaurant after dinner and wanting to eat again or feeling the urge to urinate after seeing the sign for the restroom. Both the restaurant and the restroom may evoke behavior as a CMO-S, given previous pairings with food deprivation and a full bladder, respectively.

28. A stimulus that acquires MO effectiveness by preceding some form of worsening or improvement is called a *reflexive CMO* (CMO-R). It is exemplified by the warning stimulus in a typical escape–avoidance procedure, which establishes its own offset as reinforcement and evokes all behavior that has accomplished that offset.

29. A stimulus that has preceded some form of improvement may also function as a CMO-R by (a) establishing its own offset as an effective punisher and (b) abating any behavior that has been so punished.

30. The CMO-R has usually been interpreted as an S^D. The CMO-R fails to qualify as an S^D, however, because in its absence there is no MO for a reinforcer that could be unavailable and thus no reinforcer unavailability.

31. The CMO-R identifies a negative aspect of many everyday interactions that otherwise would be interpreted as a sequence of opportunities for positive reinforcement. One example is a request for information, which initiates a brief period during which a response must be made to terminate a period of increased social awkwardness.

32. The CMO-R is often an unrecognized component of procedures used in teaching effective social and verbal behavior. Learners are asked questions or given instructions, which are followed by further intense social interaction if they do not respond to them appropriately. The question or instruction may be functioning more as a warning stimulus, as a CMO-R, than as an S^D related to an opportunity for receiving praise or other positive reinforcers.

33. An environmental variable that establishes (or abolishes) the reinforcing effectiveness of another stimulus and evokes (or abates) the behavior that has been reinforced by that other stimulus is a transitive CMO, or CMO-T.

34. Variables that function as UMOs also function as transitive CMOs for the stimuli that are conditioned reinforcers because of their relation to the unconditioned reinforcer. Food deprivation (as a UMO) establishes as a reinforcer not only food but also (as a CMO-T) all of the stimuli that have been related to obtaining food (e.g., the utensils with which one transports food to the mouth).

35. The reinforcing effectiveness of many conditioned reinforcers not only is altered by relevant UMOs but also may be dependent on other stimulus conditions. Those stimulus conditions, as CMO-Ts, then also evoke behavior that has obtained the conditioned reinforcers.

36. A CMO-T evokes behavior because of its relation to the *value* of a consequence rather than to the *availability* of a consequence.

37. The manipulation of CMO-Ts is common practice when teaching mands to individuals with disabilities. The typical procedure, termed *interrupted-chain*, involves withholding an item the learner needs to complete a previously learned task. This manipulation functions as a CMO-T, increasing the value of the item as a reinforcer, which creates the ideal condition for teaching the learner to mand for it.

Relevance of MOs to the Generality of Treatment Effects

38. An acquired behavior may not occur in the future in a new setting if the MO is absent. Thus, it is possible that generalization and maintenance failures are not only a function of novel (generalization) stimuli being dissimilar to those present during training, but also due to different MOs.

39. When programming for generalization, clinicians must do so not only across different discriminative stimuli but also across different MOs. For a newly acquired response to be generalized and maintained, its relevant MO must also be in effect.

Relevance of MOs to Applied Behavior Analysis

40. Applied behavior analytic research has shown the effects of MOs on a multitude of behaviors across a variety of conditions. MOs have affected the results of preference assessments and functional analyses, engagement with activities, within-session responding, social initiations, the rate of acquisition of target behaviors, and the occurrence of challenging behaviors.

41. Research on MOs allowed behavior analysts to recognize that the three-term contingency is dependent upon a fourth variable that modulates the effectiveness of reinforcement, and hence the evocative strength of the discriminative stimuli.

42. A clear understanding of MOs seems critical not only for interpreting and assessing results but also for designing effective behavior analytic interventions.

43. Given the ubiquity of motivational variables in our lives, a complete understanding of human behavior demands an analysis of the critical roles of MOs.

KEY TERMS

abative effect
abolishing operation (AO)
behavior-altering effect
conditioned motivating operation (CMO)
establishing operation (EO)
evocative effect
function-altering effect
motivating operation (MO)
reflexive conditioned motivating operation (CMO-R)
reinforcer-abolishing effect
reinforcer-establishing effect
surrogate conditioned motivating operation (CMO-S)
transitive conditioned motivating operation (CMO-T)
unconditioned motivating operation (UMO)
MO unpairing
value-altering effect

MULTIPLE-CHOICE QUESTIONS

1. _________ alters the effectiveness of some object or event as a reinforcer and the current frequency of all behavior that has been reinforced by that stimulus, object, or event.
   a. Discriminative stimulus
   b. Establishing operation
   c. Behavior-altering effects
   d. Value-altering effects

   Hint: (See "Definition and Characteristics of Motivating Operations")

2. The term _________ has been suggested to replace the term establishing operation (EO).
   a. Motivating operation
   b. Evocative effect
   c. Abative effect
   d. Abolishing operation

   Hint: (See "Definition and Characteristics of Motivating Operations")

3. The effect that can produce either an increase or decrease in the reinforcing effectiveness of some stimulus, object, or event is the:
   a. Behavior-altering effect
   b. Abative effect
   c. Evocative effect
   d. Value-altering effect

   Hint: (See "Definition and Characteristics of Motivating Operations")

4. The effect that can produce either an increase or decrease in the current frequency of behavior that has been reinforced by some stimulus, object, or event is the:
   a. Behavior-altering effect
   b. Abative effect
   c. Evocative effect
   d. Value-altering effect

   Hint: (See "Definition and Characteristics of Motivating Operations")

5. Motivating operations (MOs) and S^Ds are both
   a. Antecedent variables that alter the future frequency of some behavior
   b. Consequent variables that alter the current frequency of some behavior
   c. Antecedent variables that alter the current frequency of some behavior
   d. Consequent variables that alter the future frequency of some behavior

   Hint: (See "Distinguishing Between MOs and S^Ds")

6. _________ control(s) a type of behavior because it has been related to the differential availability or an effective reinforcer for that type of behavior.
   a. Motivating operations (MOs)
   b. Unconditioned motivating operations (UMOs)
   c. Conditioned motivating operations (CMOs)
   d. Discriminative stimulus (S^D)

   Hint: (See "Distinguishing Between MOs and S^Ds")

7. _________ is (are) related to the differential reinforcing effectiveness of a particular type of environmental event.
   a. Motivating operations
   b. Discriminative stimulus
   c. Motivating variables
   d. Discriminative operations

   Hint: (See "Distinguishing Between MOs and S^Ds")

8. This type of motivating operation has value-altering effects that are not learned.
   a. Conditioned motivating operations
   b. Unconditioned motivating operations
   c. Surrogate motivating operations
   d. Reflexive motivating operations

   Hint: (See "Unconditioned Motivating Operations (UMOs)")

9. Which of the following is an example of a UMO as it relates to humans?
   a. Getting paid for a job every two weeks
   b. Putting on a sweater to go outside
   c. Sleeping after a week of not getting any sleep
   d. Playing with your children after they have been in school all day

   Hint: (See "Unconditioned Motivating Operations (UMOs)")

10. The type of motivating operation that accomplishes what the original motivating operation it was paired with did is a
    a. Surrogate CMO
    b. Transitive CMO
    c. Reflexive CMO
    d. Substantive CMO

    Hint: (See "Conditioned Motivating Operations (CMOs)")

11. This type of motivating operation alters a relation to itself by acquiring MO effectiveness by preceding a worsening or improvement.
   a. Surrogate CMO
   b. Transitive CMO
   c. Reflexive CMO
   d. Substantive CMO
   Hint: (See "Conditioned Motivating Operations (CMOs)")

12. This type of motivating operation makes something else effective as a reinforcer because of its relation or association with an unconditioned reinforcer.
   a. Surrogate CMO
   b. Transitive CMO
   c. Reflexive CMO
   d. Substantive CMO
   Hint: (See "Conditioned Motivating Operations (CMOs)")

13. This type of motivating operation has particular implications for the training of language in individuals with little or no speech.
   a. Surrogate CMO
   b. Transitive CMO
   c. Reflexive CMO
   d. Substantive CMO
   Hint: (See "Conditioned Motivating Operations (CMOs)")

14. The continued study of motivating operations is most important to understanding in what field of applied behavior analysis?
   a. The three-term contingency
   b. How people learn
   c. Why people learn
   d. How to best refine the terminology
   Hint: (See "Relevance of MOs to Applied Behavior Analysis")

ESSAY-TYPE QUESTIONS

1. Define and discuss the characteristics of an establishing operation, or motivating operation (MO), and the recent movement to changing terminology.
   Hint: (See "Definition and Characteristics of Motivating Operations")
2. Discuss the similarities and differences between motivating operations (MOs) and discriminative relations.
   Hint: (See "Distinguishing Between MOs and S^Ds")
3. Define and discuss examples of unconditioned motivating operations (UMOs) related to the human organism.
   Hint: (See "Unconditioned Motivating Operations (UMOs)")
4. Given the unconditioned motivating operation (UMO) of food deprivation for an organism, describe the reinforcer-establishing and evocative effect that accompanies the UMO. Suppose food is subsequently ingested by the organism. Now describe the reinforcer-abolishing and abative effects.
   Hint: (See "Unconditioned Motivating Operations (UMOs)" and chapter examples)
5. Discuss the evocative effect on current behavior as a UMO and the function-altering effect on future behavior as punishment given the environmental variable of becoming too cold.
   Hint: (See "Unconditioned Motivating Operations (UMOs)" and chapter examples)
6. Define conditioned motivating operations (CMOs) and the various types of CMOs, and how each of these types operates.
   Hint: (See "Conditioned Motivating Operations (CMOs)")
7. What are some implications for the use of motivating operations (MOs) in the study and future of behavior analysis?
   Hint: (See "Relevance of MOs to Applied Behavior Analysis")

NOTES

1. Skinner (1938) used the term *drive* to express the relationships between operations other than reinforcement, such as deprivation, and changes in behavior. Even though Skinner found the term useful to describe these functional relations, he acknowledged it to be an inferred state between these operations and behavior and noted that the term was "not actually required in a descriptive system" (p. 368).
2. For an account of the history of the concept, see Miguel (2013).
3. The direct evocative effect suggests that the MO evokes behavior directly, in the absence of an S^D. However, we must be careful not to ignore that one of the defining features of an operant is the stimuli in the presence of which it occurs (Catania, 2013).
4. Michael (1986, 2004) used the terms "repertoire-altering effect" and "function-altering effect" to classify operations (e.g., reinforcement) that would change the future probability of an organism's behavior, as well as alter the function of stimuli.
5. Even though this is an example of manipulating an MO (i.e., task difficulty), the same argument applies to the manipulation of S^Ds. If problem behavior is more likely to occur in the presence of Dad (S^D) and not in the

presence of Mom (S^{Δ}), removing Dad from the room (eliminating the S^D) would only temporarily reduce (abate) the frequency of problem behavior. When Dad returns, the child is likely to misbehave again.

6. An individual's quality of life may be threatened by socially impoverished and/or extremely aversive environments, which may lead to the development of attention and escape-maintained problem behaviors. In addition to being an ethical necessity, improving the environment would reduce current problem behavior and help prevent its future occurrence.
7. It is true that pain reduction as a form of reinforcement is unavailable in the absence of pain, and also, food reinforcement is, in a sense, unavailable in the absence of food deprivation, but this is not the kind of unavailability that occurs in discrimination training and that develops the evocative effect of an S^D (Michael, 1982).
8. The terms *unconditioned* and *conditioned* modify MOs in the same way they modify respondent-eliciting stimuli and operant reinforcers and punishers. The effects of unconditioned motivating operations, like unconditioned eliciting stimuli for respondent behavior and unconditioned reinforcers and punishers, are not dependent on the organism's learning history. The effects of conditioned motivating operations, like the effects of conditioned eliciting stimuli and conditioned reinforcers and punishers, *are* dependent on a learning history.
9. Some of this aggression may be elicited by pain functioning as a respondent unconditioned stimulus (Ulrich & Azrin, 1962).
10. For a discussion of Skinner's approach to emotional predispositions in the general context of MOs, see Michael (1993, p. 197).
11. It is sometimes argued that behavioral principles are too simplistic for analyzing complex human behavior, and therefore some nonbehavioral—usually cognitive—approach is required. It may be that the behavioral repertoire of the people who make this argument is too simple for the task. However, behavioral principles themselves are not so simple, as can be seen from the preceding effort to understand the effects of punishment MOs, or the learned functions of painful stimulation.
12. The sound of the buzzer will also function as a respondent conditioned eliciting stimulus for smooth muscle and gland responses typically elicited by food in the mouth, and will condition such responses to any other stimulus that is present at that time—an instance of higher order classical conditioning (see Chapter 2)—but the current chapter discusses operant relations only.
13. The term *discriminated avoidance* arose so that this type of procedure could be distinguished from an avoidance procedure in which an exteroceptive stimulus change does not precede the shock itself (called *avoidance without a warning stimulus, non-discriminated avoidance*, or *free-operant avoidance*). See Chapter 12.
14. The evocative effect of CMO-Ts is not easily confused with the evocative effect of an S^D. If one can see food deprivation as an MO (rather than an S^D) with respect to the behavior that has been reinforced with food, then its function as an MO (rather than an S^D) with respect to behavior that has been reinforced with the various food-related conditioned reinforcers is an easy extension.
15. This scenario was first described in Michael (1982). At that time CMO-T was called an *establishing stimulus*, or S^E.
16. See Chapter 2, Box 2.2, "When the Phone Rings."
17. If removal of darkness is to be considered an unconditioned reinforcer, then sudden darkness would establish the value of its removal as a UMO.

CHAPTER 17

Stimulus Control

LEARNING OBJECTIVES

- Define and provide examples of stimuli and stimulus classes.
- Define and provide examples of stimulus control.
- Define and provide examples of establishing operations.
- Define and provide examples of stimulus generalization and stimulus discrimination.
- Explain how differential reinforcement is used to establish stimulus control (i.e., discrimination training procedures).
- Explain how stimulus control and stimulus generalization are used to produce concept formation.
- Describe how to use response and stimulus prompts to establish stimulus control.
- Describe how to use response and stimulus prompt fading to transfer stimulus control to the relevant stimulus.

In addition to selecting and maintaining operant behavior, reinforcement confers controlling function to antecedent stimuli whose presence or absence coincides with the organism's differential contact with it. Drivers step on the brakes when approaching stop signs, red traffic lights, and street-crossing pedestrians more often than they do in the absence of those stimuli. Bilingual speakers switch languages to match the language of their listeners. Baseball pitchers throw fastballs, curves, or change-ups, depending on signals from their catchers.

Control by antecedent stimuli plays a fundamental role in social, educational, treatment, and therapeutic environments. It can help us understand how behaviors considered appropriate in one context are inappropriate when emitted in another context. Loud talking is appropriate on the playground, but not in the classroom. Arriving 15 to 20 minutes late is appropriate for a party, but not for a job interview. Some behaviors considered inappropriate by parents, teachers, and society in general are not behavior problems per se. The problem is emitting behaviors at times, in places, or in circumstances deemed inappropriate by others. This represents a problem of stimulus control, and it is a major concern for applied behavior analysts.

This chapter describes basic concepts and processes for understanding stimulus control, methods for developing stimulus control, and techniques for transferring stimulus control from contrived antecedents to naturally occurring stimuli.

STIMULUS CONTROL: BASIC CONCEPTS AND PROCESSES

This section describes basic concepts and processes essential to understanding stimulus control: stimulus discrimination, stimulus generalization, faulty stimulus control, conditional stimulus control, respondent eliciting and operant discriminative functions of antecedent stimuli, and discriminative and motivational functions of antecedent stimuli.

Stimulus Discrimination

In a basic laboratory demonstration of operant conditioning, a rat is placed in an experimental chamber and given the opportunity to press a lever. Following each press the rat receives a food pellet, and the rate of lever pressing increases. This simple demonstration of reinforcement as a *two-term contingency* (operant response → reinforcement) seldom occurs outside of laboratory research (Pilgrim, 2015).

Manipulating the presence of antecedent stimuli in concert with the availability of reinforcement makes the contingency more complex and demonstrates how an organism's behavior can come under control of the environmental context. For example, a buzzer sounds occasionally and the rat receives a food pellet after lever presses when the buzzer is sounding, but lever presses in the absence of the buzzer sound produce no food pellets. Under these experimental conditions, the buzzer sound is called a **discriminative stimulus** (S^D, pronounced "ess-dee") and its absence is called **stimulus delta** (S^Δ, pronounced "ess-delta"). After some experience with this arrangement, the rat will press the lever more often in the presence of the buzzer sound than in its absence.

This *three-term contingency* (discriminative stimulus → *operant response → reinforcement*) is "considered the basic unit of analysis in the analysis of operant behavior" (Glenn, Ellis, & Greenspoon, 1992, p. 1332). Behavior that occurs more often in the presence of an S^D than in its absence is said to be under **stimulus control**. Technically, stimulus control occurs when the rate, latency, duration, or magnitude of a response is altered in the presence of an antecedent stimulus (Dinsmoor, 1995a, 1995b).

A stimulus acquires control only when responses emitted in the presence of that stimulus produce more reinforcement than do responses in the absence of stimulus. When the S^D signals a rich schedule of reinforcement and the S^Δ signals a zero chance of reinforcement (i.e., extinction), the organism will eventually respond only in the presence of the S^D and emit no responses in the S^Δ condition. In such cases, **stimulus discrimination** is achieved.

As introduced in Chapter 2, an S^D evokes behavior because its presence has been correlated with the *differential availability* of an effective reinforcer. That is, responses emitted in the presence of the S^D have produced reinforcement in the past, and responses emitted in its absence (S^Δ) have resulted in no reinforcement (extinction) or reinforcement of lesser quality or on a leaner schedule than the reinforcement available in the presence of the S^D (Michael, 2004). The development of stimulus control does not require an all-or-nothing face-off of reinforcement versus extinction conditions. While taking a break from working on this chapter by raking leaves, one of the authors of this text experienced an everyday example of stimulus control created by an S^Δ condition that entailed less reinforcement than the S^D condition.

> After raking several big piles of leaves from the front lawn to the curb, where the city vacuums them up for compost, I dropped the rake and took off my jacket. I picked up the rake and started on a new patch of lawn. But this time, each response with the same sweeping motion of the rake that was so efficient moments before moved fewer leaves. I looked down and saw I was holding the rake with its tines facing up (S^Δ) instead of down (S^D). From then on, I held the rake tines down!

Stimulus Generalization

In contrast to stimulus discrimination, **stimulus generalization** refers to the extent to which stimuli other than the S^D acquire stimulus control over the behavior. Stimuli sharing similar physical properties with the S^D are most likely to acquire evocative function. Stimulus generalization and discrimination are relative concepts. Stimulus generalization reflects a loose degree of stimulus control, whereas stimulus discrimination indicates a tight degree of control. Stimulus generalization can be observed when a young child who has been reinforced for saying "daddy" in the presence of her father says "daddy" in the presence of her father's two brothers. Further conditioning in the form of differential reinforcement—praise or other reinforcers for "daddy" in the presence of the child's father or photos and other likenesses of him and no reinforcement for "daddy" in the presence of her two uncles—will sharpen the degree of stimulus control to one stimulus class, the child's father and likenesses of him.

Stimulus generalization occurs with new stimuli that share similar physical dimensions with the controlling antecedent stimulus. For instance, if a behavior has a history of producing reinforcement in the presence of a blue stimulus, stimulus generalization is more likely with a lighter or darker color of blue than with a red or yellow stimulus. Also, stimulus generalization is likely when the new stimuli have other elements (e.g., size, shape) in common with the controlling stimulus. A student whose behavior has produced reinforcement for making a response to a circle is more likely to make the same response to an oval shape than to a triangular shape.

A **stimulus generalization gradient** graphically depicts the degree of stimulus generalization and discrimination by showing the extent to which responses reinforced in one stimulus condition are emitted in the presence of untrained stimuli. The slope of the gradient indicates the degree of generalization. When the slope of the gradient is relatively flat, little stimulus control is evident. However, an increasing slope of the gradient shows more stimulus control. The gradients are typically presented as rate, count (i.e., total number), or percentage of total number across all stimuli (see Figure 17.1).

Behavior analysts have used several procedures to produce stimulus generalization gradients. The classic technique of Guttman and Kalish (1956) provides a representative example. Their technique is important because many prior researchers had obtained stimulus generalization gradients by conditioning groups of subjects on the same stimulus value and then testing them individually, each with a different stimulus value. Obviously, this type of technique cannot demonstrate the degree of stimulus control for individual subjects. Guttman and Kalish provided a method of acquiring gradients for each subject and laid the foundation for greater understanding of the principles governing stimulus control.

Guttman and Kalish (1956) reinforced pigeons on a variable interval (VI) 1-min schedule for pecking a disk illuminated with a light source appearing yellow-green to humans (i.e., a wavelength of 550 mμ). After the rate of pecking the yellow-green disk had stabilized, the pigeons were tested under extinction conditions on the original stimulus and a randomized series of 11 different wavelengths never presented during training as the test for stimulus generalization.

Stimulus generalization occurs with responses to a new stimulus after a response has been conditioned in the presence of another similar stimulus. If responding produces reinforcement during testing for stimulus generalization, it cannot be clear

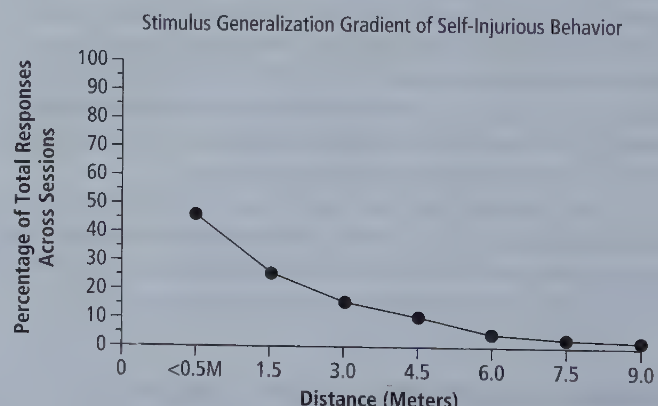

Figure 17.1 Percentage of total responses across sessions at a given distance during generalization tests. <0.5, 1.5, 3.0, 4.5, 6.0, 7.5, and 9.0 refer to the distance (in meters) between the therapist and the participant.

"Assessment of Stimulus Generalization Gradients in the Treatment of Self-Injurious Behavior", J. S. Lalli, F. C. Mace, K. Livezey, and K. Kates, 1998, Journal of Applied Behavior Analysis, 31, p. 481. Reproduced with permission of John Wiley & Sons Inc.

whether any responses to a new stimulus after the first response represent generalization or if the responses are a function of the reinforcement schedule. Guttman and Kalish (1956) avoided this problem of confounding their results by testing for generalization during extinction.

Lalli, Mace, Livezey, and Kates (1998) reported an excellent applied example of assessing and displaying a stimulus generalization gradient. They used a stimulus generalization gradient in an assessment of the relation between the physical proximity of an adult and the self-injurious behavior (SIB) of a 10-year-old girl with severe intellectual disabilities. The results presented in Figure 17.1 show that the percentage of total SIB across sessions became progressively lower as the distance between the therapist and the girl increased.

Faulty Stimulus Control

Faulty stimulus control occurs when a behavior comes under the restricted control of an irrelevant antecedent stimulus. Instructional materials students can complete with 100% accuracy without attending to the critical stimulus features of the material are widely used in primary and secondary classrooms. Figure 17.2 is an example of a worksheet likely to engender faulty stimulus control. Students need not read anything but the highlighted word at the end of each sentence to determine which picture goes with it. Other examples include a science vocabulary worksheet that can be completed without reading the definitions—the student simply matches the number of letters in each term with the number of spaces provided next to the definitions, and a language arts activity in which students construct compound words by drawing lines between the color-matched boxes (e.g., *base* and *ball* are in blue boxes, *bath* and *tub* in green boxes) without reading the words and thinking about which ones go together (Heward, 2003). Because students' answers on such poorly designed materials are under the stimulus control of irrelevant features (e.g., color, size, position on the page), the materials provide no meaningful practice with the knowledge or skills they were intended to teach.

Vargas (1984) suggested that a "Yes" answer to any of the following questions indicates that an instructional material is likely to result in faulty stimulus control over students' behavior:

1. Can students use pictures or diagrams instead of text to complete an exercise?
2. Does highlighting or physical layout give away answers, making it unnecessary to read through an assignment?

1. This is very **slick.**
2. Jim will go on the hill with his **sled.**
3. Lucy has a big hole in her **sleeve.**
4. It is time for me to go to **sleep.**
5. The dog has my **slipper.**

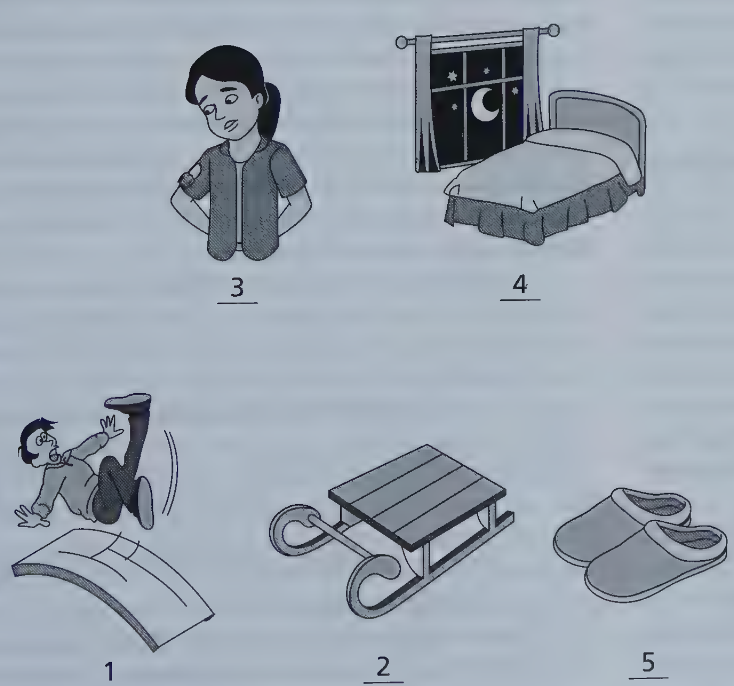

Figure 17.2 Example of instructional materials likely to engender faulty stimulus control.

From "What Are Your Exercises Teaching: An Analysis of Stimulus Control in Instructional Materials," by J. S. Vargas, 1984. In W. L. Heward, T. E. Heron, D. S. Hill, & J. Trap Porter (Eds.), *Focus on Behavior Analysis in Education* (p. 132). Copyright: Charles E. Merrill Publishing Company.

3. Are students able to answer questions on a passage without reading it?
4. Do all of the problems on a page require the same process for solution, making it unnecessary to discriminate between strategies?
5. Are the questions Jabberwocky comprehension questions—that is, can they be answered using grammatical cues alone? (p. 130)

Applied behavior analysts who work in schools should seek to detect and eliminate faulty stimulus control in instructional materials as their roles permit.

Conditional Stimulus Control

In a simple stimulus discrimination, only one antecedent stimulus controls the response. Holding a cup under the tap on a water cooler and pushing the blue lever is a simple discrimination by a person wanting cold water (see Figure 11.3). The blue lever is an S^D that signals the availability of cold water. A child touching a circle from an array of different shapes when her teacher says, "Touch the circle" is a simple discrimination. Most stimulus control in everyday life is more complex than the simple discriminations described by the three-term contingency: $S^D \rightarrow R \rightarrow S^{R+}$. Obtaining reinforcement often depends on discriminating the environmental context provided by multiple stimuli.

In a **conditional discrimination**, the response that will produce reinforcement in the presence of a particular stimulus depends on (is conditional on) the presence or absence of other stimuli. Pushing the blue (or red) lever when a friend asks, "Cold (or hot) water please," is a conditional discrimination. The friend's request is the conditional stimulus, and the color of the water tap lever is the discriminative stimulus. Conditional discrimination is evidenced in a child's correct response to the request "Point to the circle that is the same color as your shirt." The color of the child's shirt is the conditional stimulus that makes the same-colored circle the discriminative stimulus.

Respondent Eliciting and Operant Discriminative Functions of Antecedent Stimuli

At first glance, stimulus control of operant behavior appears similar to the control of respondent behavior by a conditioned stimulus. Discriminative stimuli and conditioned stimuli are antecedent stimuli whose presence increases the frequency of some behavior. Applied behavior analysts, however, need to distinguish between the evocative function of S^Ds for operant behavior and the eliciting function of conditioned stimuli for respondent behavior. This is a crucial distinction for understanding antecedent control of operant behavior.

In a typical laboratory demonstration of respondent conditioning, the experimenter presents food to a dog. The food is an unconditioned stimulus that elicits the unconditioned response—salivation. The experimenter then introduces a buzzer sound (a neutral stimulus). The buzzer sound does not elicit salivation. Then after several trials of pairing the buzzer sound with food delivery, the buzzer becomes a conditioned stimulus that elicits salivation (a conditioned response) in the absence of food (an unconditioned stimulus).

Laboratory experiments on operant and respondent conditioning have demonstrated consistently that antecedent stimuli can acquire control over a behavior. A buzzer sounds, and a rat presses a bar. A buzzer sounds, and a dog salivates. Despite the similarities, the bar press is an operant behavior, salivation is a respondent behavior, and the manner in which the S^D and the conditioned stimulus acquire their controlling functions is very different. An S^D acquires its controlling function for operant behavior by being paired with stimulus changes that occur immediately following behavior. Conversely, a conditioned stimulus acquires its controlling function for respondent behavior by being paired with other antecedent stimuli that elicit the behavior (i.e., an unconditioned stimulus or a conditioned stimulus).

Discriminative and Motivational Functions of Antecedent Stimuli

Distinguishing the nature of antecedent control of operant behavior can be difficult. Discriminative stimuli and establishing operations share two important similarities: Both occur before the behavior of interest and both have evocative functions. To evoke a behavior means to occasion it or call it up. The question often becomes, "Was a particular response evoked by a discriminative stimulus (S^D), an establishing operation (EO), or both?"

In some situations, an antecedent stimulus change evokes a response and the functional relation appears to be an S^D. For example, in a typical shock–escape procedure an animal is placed in an experimental chamber. Shock is administered until a response terminates the shock for a designated period. Then the shock is reintroduced until it is again terminated by a response, and so on. An experienced animal escapes the shock immediately. In such a situation, some would say that the shock serves as an S^D. The shock, an antecedent stimulus, evokes a response that is negatively reinforced (the shock is removed). In this situation, however, shock does not function as an S^D. To repeat an important point, an S^D evokes behavior because its presence has been correlated with the *differential availability* of an effective reinforcer. That is, responses emitted in the presence of the S^D have produced reinforcement in the past and responses emitted in its absence (S^Δ) have not.

Even though the animal receives reinforcement by terminating the shock, the absence of shock does not signal the availability of less frequent reinforcement. Before the response can be reinforced, the shock must be on. In this example, the onset of shock is an EO because it changes what *functions* as reinforcement (shock termination) rather than signaling the differential availability of reinforcement (Michael, 2000). Often the apparent S^D effect does not have a history of effective differential reinforcement correlated with the altered frequency of response. These situations are probably related to motivating operations (MOs) rather than stimulus control.

The following scenario puts the laboratory examples into an applied context: A teacher asks a student to begin working on an academic task. The student refuses to comply, disrupting the class, and the teacher withdraws the request. Later, the teacher

again requests an academic response, and the cycle of noncompliance and disruptive behavior and removal of the request continues. Although the teacher's request is an antecedent stimulus that evokes aggression that is negatively reinforced (the request is removed), it is not an S^D. Like the onset of shock in Michael's laboratory example, the teacher's request is an EO that evokes the aggressive behaviors rather than an S^D. It makes no sense to talk about an S^D evoking the aggressive behavior in the absence of the request (McGill, 1999), just as it makes no sense to talk about an S^D evoking a response in the absence of the shock. The laboratory rat is not motivated to escape shock in the absence of shock, and the student does not "want" to escape his teacher's task requests in the absence of those task requests. An antecedent stimulus functions as an S^D only when in its presence a specific behavior produces reinforcement, and in the absence of that stimulus the same behavior does not produce reinforcement (Michael, 2000).

The laboratory and classroom examples can be changed to show the difference between the evocative functions of EOs and stimulus control. The experimental conditions could change so that a buzzer sounds at different periods throughout the session, the shock would be removed only when a response is made while the buzzer is sounding, and a response would not produce reinforcement in the absence of the buzzer (i.e., the shock would not be removed). Under these conditions the buzzer would function as an S^D, and stimulus control would be demonstrated.

The classroom conditions could change so that two teachers work with the student. One teacher terminates task requests when the student is noncompliant; the other teacher does not remove the requests. In this arrangement, the presence of the first teacher signals the availability of negative reinforcement; the second teacher signals extinction. The teacher who terminates the requests to work would become an S^D that evokes noncompliant, disruptive behaviors from the student; the second teacher would become an S^Δ for noncompliance. In these modified examples, the characteristics of the antecedent control would be different in the presence and absence of the buzzer and the other teacher, and the buzzer and the other teacher would be correlated with an increased frequency of reinforcement.

An understanding of the S^D and MO evocative functions will improve technological descriptions of antecedent control and the understanding of behavior change (Laraway, Snycerski, Michael, & Poling, 2001). Ultimately, these understandings will produce greater effectiveness in education and treatment (see also Chapter 16).

DEVELOPING STIMULUS CONTROL

This section describes the major processes required for the development of stimulus control.

Stimulus Discrimination Training

The basic procedure for **stimulus discrimination training** entails a multiple schedule (Chapter 13) with antecedent stimulus conditions representing each component schedule. Responses in the presence of one stimulus condition (S^D) are reinforced, and responses in the presence of the other stimulus (S^Δ) are not reinforced. When this procedure is applied appropriately and consistently, responding in the presence of the S^D will come to exceed responding in the presence of the S^Δ. Often, over time, the participant will learn not to respond in the presence of the S^Δ.

Applied behavior analysts often describe the conventional procedures for discrimination training, with differential reinforcement as alternating conditions of reinforcement and extinction, meaning that a response produces reinforcement in the S^D condition but not in the S^Δ condition. However, to clarify and stress and important point: the S^Δ is used not only to show a condition of zero reinforcement (extinction) but also to denote a condition that provides a lesser amount or quality of reinforcement than the S^D condition (Michael, 2004).

Maglieri, DeLeon, Rodriguez-Catter, and Sevin (2000) used discrimination training as part of an intervention to decrease the food stealing of a 14-year-old girl with Prader-Willi syndrome, a serious medical condition usually correlated with obesity and food stealing. During discrimination training, a teacher showed the girl two containers of cookies. One container contained a warning label, the S^Δ, and the other container had no warning label, the S^D. The teacher told the girl that she could eat cookies only from the container without the warning label. The teacher asked the girl in the presence of the two containers, "Which cookies can you eat?" If the girl answered that she could eat the cookies from the container without the warning, the teacher let her eat one cookie from the container. This discrimination training procedure decreased stealing food from the containers marked with the warning label.

Researchers have used multiple schedules to help learners develop stimulus control of social approach responses (e.g., Cammilleri, Tiger, & Hanley, 2008; Grow, LeBlanc, & Carr, 2010; Torelli, Lloyd, Diekman, & Wehby, 2016). Although teaching students to recruit teacher attention can increase teacher praise and instructional assistance and improve student academic performance (see Teach the Learner to Recruit Reinforcement in Chapter 30), classrooms are busy places and teacher attention is not continuously available. Students must be taught not only *how* to recruit teacher attention but also how to discriminate *when* recruiting is appropriate (Alber & Heward, 2000).

Cammilleri et al. (2008) used a classwide multiple-schedule procedure to bring young children's requests to teachers under stimulus control in the three primary classrooms. In two to four 5-min sessions per day throughout the study, the teachers randomly alternated wearing a green lei or a red lei. During baseline, differential consequences were not paired with each lei. The teachers responded to a student's social approach and provided academic assistance as needed. During the multiple-schedule condition, the green lei (S^D) signaled that teacher attention was available, and the red lei (S^Δ) signaled teacher attention was unavailable. Prior to each session during the multiple-schedule condition, the teacher described the contingency associated with the relevant lei: "While I am wearing the green lei, I will be able to answer your questions" or "While I am wearing the red lei, I will not be able to answer your questions" (p. 301). Student requests during the multiple-schedule condition were maintained during desirable periods and minimized during undesirable periods (see Figure 17.3).

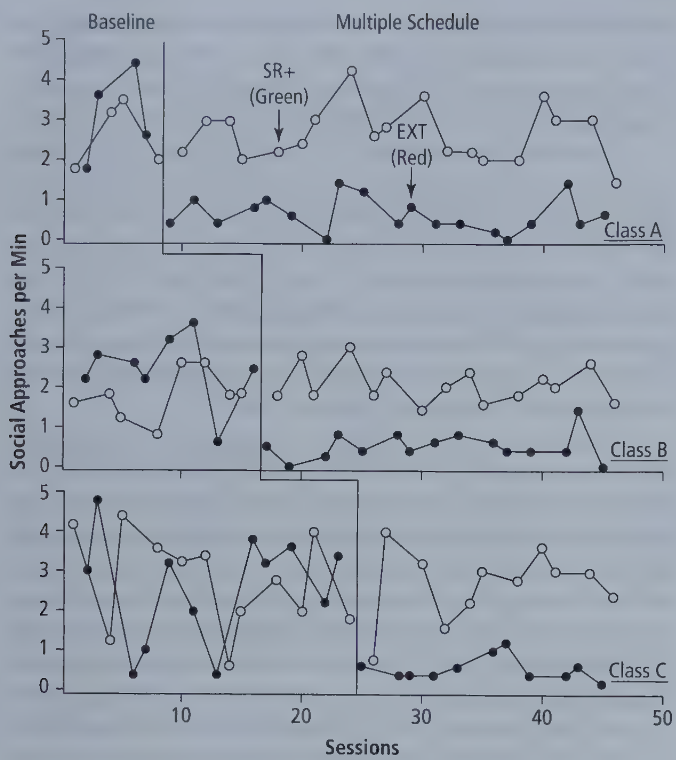

Figure 17.3 Social approach rates during baseline and multiple-schedule conditions across three elementary classrooms.

"Developing Stimulus Control of Young Children's Requests to Teachers: Classwide Applications of Multiple Schedules", A. P. Cammilleri, J. H. Tiger, and G. P. Hanley, 2008, Reproduced with permission of John Wiley & Sons Inc.

Teaching Conditional Discriminations

Skinner conducted early research on complex stimulus control with an experimental procedure called **matching-to-sample**. Dinsmoor (1995b) described Skinner's procedure in the following way. A pigeon was presented with three horizontal keys to peck. The middle key was illuminated with a color to start the trial. A peck on the illuminated key turned it off and lighted two side keys. One of the side keys was the same color as the sample color illuminated on the middle key. A peck on the side key with the same color as the sample key produced reinforcement. Error responses were not reinforced.

Skinner's matching-to-sample procedure included the *three-term contingency*:

S^D ⟶ Response ⟶ Reinforcement
Side key with color | Key peck | Grain

This basic contingency, however, is incomplete because of constraints from the environmental context. The contextual events operating on the three-term contingency become *conditional discriminations* (Sidman, 1994; Spradlin & Simon, 2011). The color of the middle key in Skinner's procedure is the conditional stimulus. The three-term contingency is effective only when it matches the sample stimulus. Reinforcement is conditional on the context of discriminative stimuli other than the S^D; that is, the three-term contingency itself comes under contextual control. Conditional discriminations operate at the level of a *four-term contingency*:

Conditional sample ⟶ S^D ⟶ Response ⟶ Reinforcement
Color of middle key ⟶ Side key same color as middle key ⟶ Key peck ⟶ Grain
S^{Δ} ⟶ Key peck ⟶
Side key different color than middle key

To start a matching-to-sample trial, the participant will make a response (called the observing response) to present the sample stimulus (i.e., the conditional sample). The comparison stimuli (i.e., the discriminative events) are presented usually after removing the sample stimulus, but not always, and provide for an effective three-term contingency and other noneffective three-term contingencies. One comparison stimulus will match the conditional sample. A response that selects the matched comparison and rejects the nonmatched comparisons will produce reinforcement. Figure 17.4 presents an example

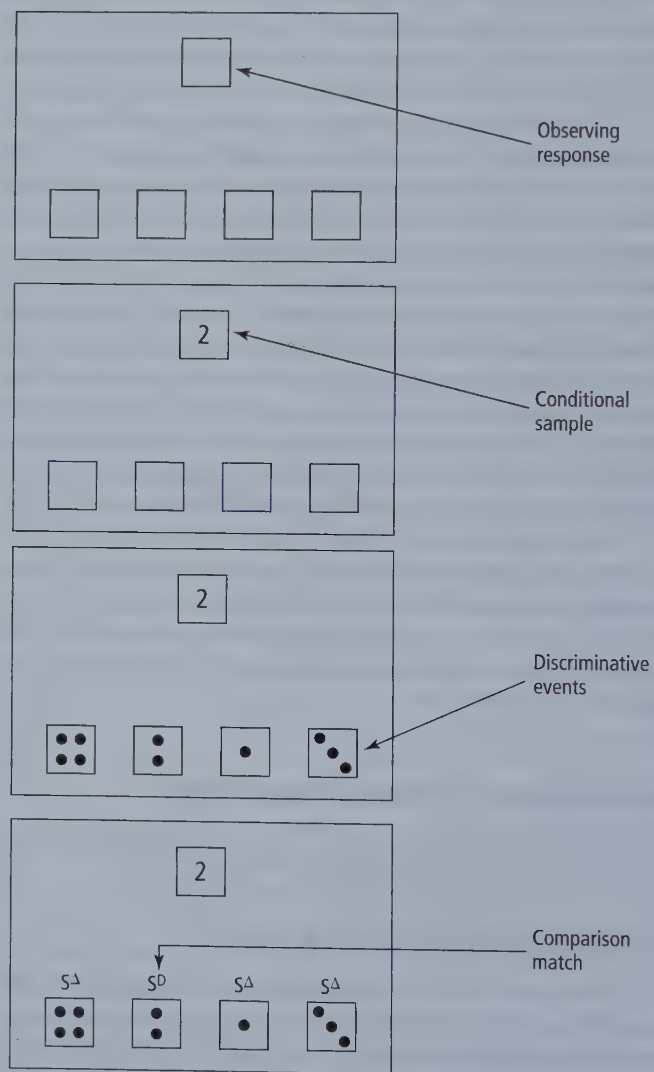

Figure 17.4 An example of the observing response, the conditional sample, the discriminative events, and the comparison match during a matching-to-sample trial.

of the observing response, the conditional sample, the discriminative events, and the comparison match. Responses that select the nonmatching comparison stimuli are not reinforced. During conditional discrimination training, the same selection must be correct with one conditional stimulus, but incorrect with one or more other sample stimuli. Most matching-to-sample applications use a correction procedure with error responses. One correction procedure has the learner respond to the same sample and comparison stimuli until a correct response has been reinforced. Error correction procedures and the random positioning of the comparison stimuli control for position responding. Numerous examples of using the matching-to-sample procedure to teach conditional discriminations are described in Chapter 19.

Teaching Concepts

The preceding section on discrimination training describes how an antecedent stimulus can acquire evocative control over a response, meaning that the behavior occurs more frequently in the presence of the stimulus than in its absence. A discrimination training procedure might be used to teach a preschool student to name the primary colors. For instance, to teach the color red, the teacher could use a red object, such as a red ball, as the S^D condition and a non-red object, such as a yellow ball, as the S^Δ condition. The teacher could position both balls randomly in front of the student, direct the student to name and point to the red ball, and reinforce correct responses, but not incorrect responses. After a few trials the red ball would acquire stimulus control over the student's response, and the student would reliably differentiate the red ball from the yellow ball. This simple discrimination training, however, is unlikely to meet the instructional objective of identifying the color red. The teacher may want the student to learn not only to discriminate between red balls and balls of different color but also the concept of *redness*. A **concept** is defined by a set of shared features found in each example of the concept (Layng, 2017).

> That is, every example of a concept shares certain *must have* features with all other examples of the concept. In addition to these *must have* features, the examples have other *can have* features, which other examples of the concept may or may not have. . . . Thus, the shared *must have* features are what define something as an example of a concept and do not change from example to example. The other nondefining features are those the example *can have*, often changing from example to example, but that don't define the example as an instance of the concept. (Layng, 2017, pp. 1–2)

Terms such as *concept formation* or *concept acquisition* imply for many people some hypothetical construct or mental process. Yet acquiring a concept is clearly dependent on responses in the presence of antecedent stimuli and the consequences following those responses. When given examples and nonexamples of a concept not presented during instruction, a learner who understands the concept can:

- Distinguish examples of the concept from similar nonexamples that lack one or more of the defining *must have* features (discrimination).
- Identify examples of the concept across a wide range of varying examples that include nondefining *can have* features (stimulus generalization). (adapted from Layng, 2017)

Concept formation is a behavioral outcome of stimulus generalization and discrimination (Keller & Schoenfeld, 1950; Zentall, Galizio, & Critchfield, 2002). Concept formation is a complex example of stimulus control that requires both stimulus generalization within a class of stimuli and discrimination between classes of stimuli. An **antecedent stimulus class** is a set of stimuli that share a common relationship. All of the stimuli in an antecedent stimulus class will evoke the same operant response class or elicit the same respondent behavior. This evocative or eliciting function is the only common property among the stimuli in the class (Cuvo, 2000). For example, consider a stimulus class for the concept *red*. A red object is called red because of a particular conditioning history. This conditioning history of differential reinforcement will evoke the response *red* to light waves of different wavelengths, from light red to dark red. These different shades of the color red that will evoke the response *red* share a conditioning history and are included in the same stimulus class. Shades of red (e.g., very light red) that do not evoke the response *red* are not members of that stimulus class. Therefore the concept of redness requires stimulus generalization from the trained stimuli to many other stimuli within the stimulus class. If the preschool student described earlier had acquired the concept of redness, he would be able to identify the red ball and, without specific training or reinforcement, choose a red balloon, a red toy car, a red pencil, and so on.

In addition to stimulus generalization, a concept requires discrimination between members and nonmembers of the stimulus class. For example, the concept of redness requires discriminating between red and other colors and irrelevant stimulus dimensions such as shape or size. The concept begins with discrimination between the red ball and the yellow ball but results in discriminating a red dress from a blue dress, a red toy car from a white toy car, and a red pencil from a black pencil.

Discrimination training is fundamental to teaching conceptual behavior. Antecedent stimuli representative of a group of stimuli sharing a common relationship (i.e., the stimulus class) and antecedent stimuli from other stimulus classes must be presented. Before a concept can be acquired, the teacher must present exemplars of what the concept is (i.e., the S^D condition) and what the concept is not (i.e., the S^Δ condition). This approach holds true for all conceptual development, even for highly abstract concepts (e.g., honesty, patriotism, justice, freedom, sharing). It is also possible to acquire a concept through vicarious discrimination training and differential reinforcement. A verbal definition of a concept, with examples and nonexamples of the concept, may be sufficient for concept formation without additional direct training.

Authors of children's literature often teach concepts vicariously, such as good and bad, honest and dishonest, courageous and cowardly. For example, consider the story of an owner of a mom-and-pop grocery store who wanted to hire a young person to work in the store. The job included sweeping the floor, bagging groceries, and keeping the shelves neat. The owner wanted an honest person to work for her, so she decided to test all applicants to see whether they were honest. The first young person who applied was given the opportunity to try the

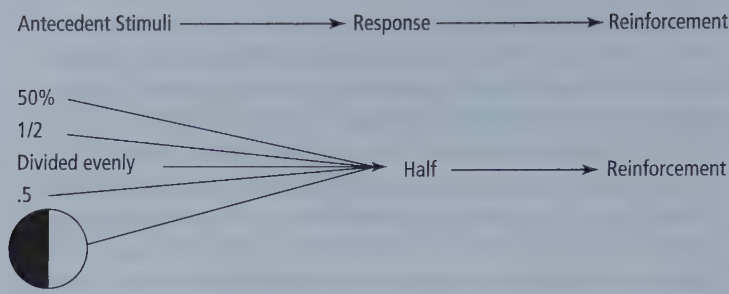

Figure 17.5 Example of an arbitrary stimulus class: Antecedent stimuli with different physical forms that evoke the same response, *half.*

job before the owner made the commitment to hire him. But before the applicant came to work, the owner hid a dollar bill where she knew the young person would find it. At the end of the test period the owner asked the applicant how he had liked working in the store, whether he wanted the job, and whether anything surprising or unusual had happened to him. The applicant replied that he wanted the job and that nothing surprising had happened to him. The grocer told the first applicant that she wanted to consider others who had also applied. The second applicant worked a test period with the same results as the first person. He did not get the job. The third young person to work for the grocer was sweeping the floor, found the dollar bill, and took it immediately to the grocer. The third applicant said he turned in the dollar bill in case one of the customers or the grocer had dropped it. The grocer asked the applicant whether he liked the job and wanted to work for her. The young person replied that he did. The grocer told the applicant that he had the job because he was an honest person. The grocer also let him keep the dollar bill.

The previous children's story presents exemplars of honest and dishonest behavior. The honest behavior was rewarded (i.e., the honest person obtained the job), and the dishonest behavior was not rewarded (i.e., the first two applicants did not get the job). This story might vicariously teach a certain concept of honesty.

Stimuli that make up a class may function within *feature stimulus classes* and *arbitrary stimulus classes* (McIlvane, Dube, Green, & Serna, 1993; Catania, 2013; Spradlin & Simon, 2014). Stimuli in a **feature stimulus class** share common physical forms (e.g., topographical structures) or common relative relations (e.g., spatial arrangements). Feature stimulus classes include an infinite number of stimuli and constitute a large portion of our conceptual behavior. For instance, the concept 'dog' is based on a feature stimulus class. The common physical forms of all dogs will be members of that stimulus class. A young child, through differential reinforcement, will learn to differentiate dogs from horses, cats, cows, and so on. Physical forms provide common relations for many feature stimulus classes, such as stimulus classes that evoke the responses book, table, house, tree, cup, cat, rug, onion, and car. A *relational*, or relative, relation exists among stimuli in other feature classes. Examples of these feature stimulus classes based on relative relations are found with concepts such as bigger than, hotter than, higher than, on top of, and to the left of.

Stimuli composing an **arbitrary stimulus class** evoke the same response, but they do not share a common stimulus feature (i.e., they do not resemble each other in physical form, nor do they share a relational relationship). For example, a teacher could form an arbitrary stimulus class using the stimuli *50%, 1/2, divided evenly, .5*, and a shaded circle (see Figure 17.5). Following training, each of these stimuli of different physical forms will evoke the same response, *half. Green bean, asparagus, potato*, and *corn* could be developed into an arbitrary stimulus class to evoke the response *vegetable*. English language students learn to associate vowels with the arbitrary class of the letters *A, E, I, O, U*, and sometimes *Y*.

The development of concepts and complex verbal relations plays an important role in parenting, caregiving, education, and treatment. Applied behavior analysts need to consider different instructional procedures when teaching concepts and complex verbal relations that produce feature stimulus classes and arbitrary stimulus classes. A common instructional procedure used with feature stimulus classes is to differentially reinforce responses to *is* (S^D) and *is not* (S^Δ) examples of the concept. Broad generalization is common with feature stimulus classes; depending on the functioning level of the participants, a few trained examples may be sufficient to develop the concept. Stimulus generalization, however, is not a characteristic of arbitrary stimulus classes. Applied behavior analysts have developed arbitrary stimulus classes by using matching-to-sample procedures to create stimulus equivalence among arbitrary stimuli (see Chapter 19).

Using Response and Stimulus Prompts

Prompts are supplementary antecedent stimuli used to occasion a correct response in the presence of the natural S^D that will eventually control the behavior. Applied behavior analysts give response and stimulus prompts before or during the performance of a behavior. **Response prompts** operate directly on the response to cue a correct response. The three major forms of response prompts are verbal instructions, modeling, and physical guidance. **Stimulus prompts** operate directly on the antecedent task stimuli to cue a correct response in conjunction with the critical S^D.

Verbal Instructions

Applied behavior analysts use functionally appropriate verbal instructions as supplementary response prompts. Verbal response prompts occur frequently in almost all training contexts in the forms of vocal verbal instruction (e.g., oral, telling) and nonvocal verbal instruction (e.g., written words, manual signs, pictures).

Teachers often use vocal verbal instructional prompts. Suppose a teacher asks a student to read the sentence "Plants

need soil, air, and water to grow." The student reads, "Plants need . . . Plants need . . . Plants need . . . " The teacher could use any number of verbal prompts to occasion the next word. She might say, "The next word is *soil*. Point to *soil* and say *soil*." Or she might use a rhyming word for *soil*. For another example, Adkins and Mathews (1997) taught in-home caregivers to use vocal verbal response prompts to improve voiding procedures for two adults with urinary incontinence and cognitive impairments. The in-home caregiver checked for dryness each hour or every 1 or 2 hours between 6:00 AM and 9:00 PM. The caregiver praised dryness, asked the adult to use the toilet, and provided assistance as needed when the adult was dry at the regularly scheduled check. This simple response prompt procedure (i.e., asked the adult to use the toilet), which was introduced following a baseline condition, produced in one of the adults a mean 22% reduction of grams of urine collected per day in wet diapers during the 2-hour prompted voiding condition, and a mean 69% reduction during the 1-hour prompt condition. The second adult received only the 1-hour prompted voiding condition, which resulted in a mean 55% reduction of urine collected per day.

Krantz and McClannahan (1998) and Sarokoff, Taylor, and Poulson (2001) used nonvocal verbal instructional response prompts in the form of embedded scripts to improve the spontaneous social exchanges of children with autism. Examples of the embedded scripts in the children's photographic activity schedules included *look, watch*, and *let's eat our snack*. In another example of nonvocal verbal instructional response prompts, Wong, Seroka, and Ogisi (2000) developed a checklist with 54 steps to prompt self-assessment of blood glucose level by a diabetic woman with memory impairments. This participant followed the checklist sequence and checked off each step as she completed it.

Modeling

Applied behavior analysts can demonstrate or model the desired behavior as a response prompt. Modeling can effectively prompt behaviors especially for learners who have already learned some of the component behaviors required for the imitation. Modeling is an easy, practical, and successful way for a coach to show a player an appropriate form for shooting a basketball through a hoop when the player already can hold the ball, raise it over his head, and push the ball away from his body. Few teachers would use modeling to teach a child with severe disabilities to tie her shoes if she could not hold the laces in her hands. In addition, attending skills are important. The learner must observe the model to enable imitation of the performance. Finally, modeling as a response prompt should be used only with learners who have already developed imitative skills. The use of models to develop a wide range of new behaviors has been demonstrated repeatedly. Chapter 21 provides a detailed discussion of modeling, imitation, and observational learning.

Physical Guidance

Physical guidance is a response prompt applied most often with young children, learners with severe disabilities, and older adults experiencing physical limitations. Using physical guidance, the teacher partially guides the student's movements or physically guides the student throughout the entire movement of the response.

Hanley, Iwata, Thompson, and Lindberg (2000) reported the use of physical guidance to help participants with profound intellectual disabilities manipulate leisure items. Conaghan, Singh, Moe, Landrum, and Ellis (1992) used physical guidance to prompt adults with intellectual disabilities and hearing impairments to use manual signs. When a participant made an error in sign production, the teacher physically guided the person's hands to prompt a correct response. In another example, a personal trainer worked with three older adults with severe disabilities, osteoporosis, and arthritis. The trainer physically guided the participants' arm movements whenever they did not begin independent pushes with a dumbbell or stopped the pushes before reaching their exercise criterion (K. Cooper & Browder, 1997).

Physical guidance can be an effective response prompt, but it is more intrusive than verbal instruction and modeling. It requires direct physical contact between the teacher and the student, making precise assessment of student progress difficult. Even though some learners require physical guidance, such response prompts provide little opportunity for the student to emit the behavior without the direct assistance of the teacher. Another possible problem is that some learners resist physical touch.

Stimulus Prompts

Applied behavior analysts frequently use movement, position, and redundancy of antecedent stimuli as stimulus prompts. For example, movement prompts can help a learner discriminate between a penny and a dime by pointing to, tapping, touching, or looking at the coin to be identified. In the coin discrimination task, the teacher could use a position prompt and place the correct coin closer to the student. Redundancy prompts occur when one or more stimulus or response dimensions (e.g., color, size, shape) are paired with the correct choice. For instance, a teacher might use a color mediation procedure of associating a numeral with a color, then link the name of a color to an answer for an arithmetic fact (Van Houten & Rolider, 1990).

Practitioners must be aware that there is a risk of prompt dependence with the applications of response and stimulus prompts (e.g., Grow & LeBlanc, 2013). Prompt dependence results from a failure to transfer stimulus control from the prompt to the desired stimuli. The basic research foundations and procedures for the transfer of stimulus control are presented later in this chapter.

Factors Affecting the Development of Stimulus Control

Applied behavior analysts establish stimulus control with frequent differential reinforcement of behavior in the presence and absence of the S^D condition. Effective differential reinforcement requires the consistent use of consequences that function as reinforcers. Additional factors such as preattending skills, stimulus salience, masking, and overshadowing also will affect the development of stimulus control.

Preattending Skills

The development of stimulus control requires certain prerequisite skills. For academic or social skills, the student should engage in orienting behaviors appropriate to the S^Ds in the instructional setting. Such preattending skills include looking at the instructional materials, looking at the teacher whenever a response is modeled, listening to oral instructions, and sitting quietly for short periods. Teachers should use direct behavioral interventions to specifically teach preattending skills to learners who have not developed these skills. Learners must emit behaviors that orient their sensory receptors to the appropriate S^D for the development of stimulus control.

Stimulus Salience

The salience of a stimulus (i.e., the prominence of the stimulus in the learner's environment) influences attention to it and ultimately the development of stimulus control (Dinsmoor, 1995b). For example, Conners and colleagues (2000) included salient cues (e.g., specific room color, specific therapist) into the context of multielement functional analyses (see Chapter 27). Their results suggested that salient cues facilitated the efficiency of functional analyses by producing faster and clearer outcomes in the presence of the salient cues than in the absence of them.

Some stimuli have more salience than others, depending on the sensory capabilities of the individual, the past history of reinforcement, and the context of the environment. For instance, a student may not attend to words written on the blackboard because of poor vision, or to the teacher's oral directions because of poor hearing, or to curriculum materials because of past failures to learn, or to teacher directions because of focusing attention on a toy in the student's desk.

Catania (2013) clarified the common use of the term *salience* (as we have used it here) when he stated that "salience isn't a property of a stimulus; it is actually a property of the organism's behavior with respect to that stimulus" (p. 140). We can say this another way: Although a behavior analyst can change various aspects (e.g., size, position, color) of a stimulus in an effort to increase its salience, whether or not salience is achieved is determined by the learner's differential responding (or lack thereof) to those changes.

Overselective Stimulus Control

In **overselective stimulus control** (also called *stimulus overselectivity*) the range of discriminative stimuli or stimulus features controlling behavior is extremely limited (Lovaas, Koegel, & Schreibman, 1979). Some children with autism or intellectual disabilities focus on a minute feature of an object or a person rather than the whole (Dube et al., 2016; Ploog, 2010). For example, if shown a guitar for the first time, a child might focus on the sound hole and not consider anything else about the instrument, such as its size, shape, other parts, or even the sound it makes. This selective stimulus control interferes with the child's understanding of what a guitar is—the totality of its parts and function. Overselective stimulus control hinders a child's ability to interpret relevant meaning from the environment and to learn new concepts and academic and language skills.

Several studies have demonstrated that teaching learners to emit more elaborate observing responses before making a selection response can improve the performance of learners in matching-to-sample activities (Doughty & Hopkins, 2011; Dube & McIlvane, 1999; Gutowski & Stromer, 2003). The elaborated observing response used by Farber, Dickson, and Dube (2017) to improve the performance of participants with overselective stimulus control was described as follows:

> In typical matching procedures, the sample stimuli are presented first, the student makes an observing response to the samples, and then an array of comparison stimuli is presented, one of which is correct in relation to the samples. Observing responses to sample stimuli may be classified as nondifferential or differential. With nondifferential observing responses, the response to samples is the same on every trial and the only discrimination required is between the presence versus absence of the stimuli. By contrast, differential observing responses (DORs) include behavioral requirements that verify discrimination of stimulus features that differ among the samples. For example, if the sample stimuli are pictures, one type of DOR would be to name the pictures aloud (e.g., Constantine & Sidman, 1975). (Farber et al., 2017, p. 88)

Stimulus Blocking and Overshadowing

Stimulus blocking and overshadowing are methods for decreasing the salience of stimuli (Dinsmoor, 1995b). In **stimulus blocking** (sometimes called *masking*), even though one stimulus has acquired stimulus control over behavior, a competing stimulus can block the evocative function of that stimulus (Didden, Prinsen & Sigafoos, 2000; Seraganian & vom Saal, 1969). For example, a student may know the answers to a teacher's questions, but will not respond in the presence of the peer group, which in this example is competition of different contingencies of reinforcement, not just an antecedent stimulus that makes it harder to "attend to" the relevant S^D. In **overshadowing**, the most salient component of a compound stimulus arrangement controls responding and interferes with the acquisition of stimulus control by the more relevant stimulus. For example, Dittlinger and Lerman (2011) found that pictures in text delayed acquisition of sight word reading by children with developmental disabilities, suggesting that pictures overshadowed the text and may have interfered with learning. Fading in the pictures using a least-to-most prompting hierarchy and a text-to-picture matching response requiring students to attend to both the text and the picture have proved effective against overshadowing (Richardson et al., 2017).

Applied behavior analysts need to recognize that blocking and overshadowing can hinder the development of stimulus control and apply procedures that reduce these effects. Examples of reducing the influence of blocking and overshadowing include (a) rearranging the physical environment (e.g., lowering the window shade, removing distractions, changing seating assignments), (b) making instructional stimuli appropriately intense (e.g., providing a rapid pace of instruction, many opportunities to respond, an appropriate level of difficulty, and opportunities

to set goals), and (c) consistently reinforcing behavior in the presence of the instructionally relevant discriminative stimuli.

TRANSFERRING STIMULUS CONTROL

Applied behavior analysts should provide response and stimulus prompts as *supplementary* antecedent stimuli only during the acquisition phase of instruction. With the reliable occurrence of behavior, applied behavior analysts need to transfer stimulus control from the response and stimulus prompts to the naturally existing stimulus. Applied behavior analysts transfer stimulus control by gradually fading stimuli in or out, gradually presenting or removing antecedent stimuli. Eventually, the natural stimulus, a partially changed stimulus, or a new stimulus will evoke the response. Fading response prompts and stimulus prompts is used to transfer stimulus control from the prompts to the natural stimulus, and also to minimize the number of error responses occurring in the presence of the natural stimulus. For a review of response-prompt and stimulus-prompt fading procedures, see Cenghar, Budd, Farrell, and Fienup (2018).

Basic Research Foundations

Terrace's (1963a, b) influential research on the transfer of stimulus control using fading and superimposition of stimuli provides classic examples of transferring stimulus control. In these studies, Terrace taught pigeons to make red–green and vertical–horizontal discriminations with a minimum of errors. His use of techniques for gradually transferring stimulus control was called **errorless learning**. To teach a red–green discrimination, Terrace presented the S^{Δ} (red light) at the beginning of discrimination training, before the S^D (green light) had stimulus control over the pigeon's responses. The initial introduction of the red light was with low illumination and for brief time intervals. During successive presentations of the stimuli, Terrace gradually increased the intensity of the red light and the duration it was illuminated until it differed from the green light only in hue. With this procedure, Terrace taught pigeons to discriminate red from green with only a minimum number of errors (responses to the S^{Δ}).

Terrace further demonstrated that stimulus control acquired with red and green lights could be transferred to vertical and horizontal lines with a minimum number of errors (i.e., responses in the presence of the S^{Δ}). His procedure consisted of first superimposing a white vertical line on the green light (S^D) and a white horizontal line on the red light (S^{Δ}). Then the pigeons were given several presentations of the two compound stimuli. Finally, the amplitude of the red and green lights was reduced gradually until only the vertical and horizontal lines remained as stimulus conditions. The pigeons showed almost perfect transfer of stimulus control from the red–green lights to the vertical–horizontal lines. That is, they emitted responses in the presence of the vertical line (S^D) and seldom responded in the presence of the horizontal line (S^{Δ}).

Following Terrace's work, other pioneer researchers (e.g., Moore & Goldiamond, 1964) produced landmark studies showing that the transfer of stimulus control with few incorrect responses was possible with human learners, which provided the foundations for developing effective procedures to transfer stimulus control from response prompts to natural stimuli in the applied context.

Transferring Stimulus Control from Contrived Response Prompts to Naturally Existing Stimuli

Wolery and Gast (1984) described four procedures for transferring stimulus control from response prompts to natural stimuli. They describe these procedures as most-to-least prompts, graduated guidance, least-to-most prompts, and time delay.

Most-to-Least Prompts

The applied behavior analyst can use most-to-least response prompts to transfer stimulus control from response prompts to the natural stimulus whenever the participant does not respond to the natural stimulus or makes an incorrect response. To apply **most-to-least response prompts**, the analyst physically guides the participant through the entire performance sequence, and then gradually reduces the amount of physical assistance provided as training progresses from trial to trial and session to session. Customarily, most-to-least prompting moves from physical guidance to visual prompts to verbal instructions, and finally to the natural stimulus without prompts.

Graduated Guidance

The analyst provides physical guidance as needed, but using graduated guidance she will immediately start to fade out the physical prompts to transfer stimulus control. Graduated guidance begins with the applied behavior analyst following the participant's movements closely with her hands, but not touching the participant. The analyst then increases the distance of her hands from the participant by gradually changing the location of the physical prompt. For example, if the analyst used physical guidance for a participant's hand movement in zippering a coat, she might move the prompt from the hand to the wrist, to the elbow, to the shoulder, and then to no physical contact. Graduated guidance provides the opportunity for an immediate physical prompt as needed.

Least-to-Most Prompts

When transferring stimulus control using **least-to-most response prompts**, the applied behavior analyst gives the participant an opportunity to perform the response with the least amount of assistance on each trial. The participant receives greater degrees of assistance with each successive trial without a correct response. The procedure for least-to-most prompting requires the participant to make a correct response within a set time limit (e.g., 3 seconds) from the presentation of the natural S^D. If the response does not occur within the specified time, the applied behavior analyst presents the natural S^D and a response prompt of least assistance, such as a verbal response prompt. If after the same specified time limit (e.g., another 3 seconds) the participant does not make a correct response, the analyst gives the natural S^D and another response prompt, such as a gesture. The participant receives partial or full physical guidance if the lesser prompting does not evoke a correct response.

Applied behavior analysts using the least-to-most response prompt procedure present the natural S^D with the same time limit for an unprompted correct response each trial. For example, Heckaman, Alber, Hooper, and Heward (1998) used instructions, nonspecific verbal prompts, modeling, and physical prompting in a least-to-most 5-sec response prompt hierarchy with four students with autism.

Based on the results of two studies in which they compared the effectiveness of most-to-least and least-to-most prompting on the acquisition of solitary play skills by children with autism, and previous research, Libby, Weiss, Bancroft, and Ahearn (2008) recommended the following guidelines for selecting prompting techniques:

- Most-to-least should be the default prompting technique when a child's learning history is unknown.
- If errors have been found to evoke problem behavior or impede learning, most-to-least or most-to-least with time delay is preferable. (Time delay is described in the following section.)
- Least-to-most may be preferable for students who have shown rapid skills acquisition with this technique.
- In all cases, progress should be monitored to ensure errors do not impede learning. (adapted from Libby et al., 2008)

Time Delay

Touchette (1971) discovered that inserting small increments of time between presentation of the instructional stimulus and a response prompt across trials resulted in the learner "anticipating" the correct response. A **time delay** procedure begins with simultaneous presentation of the target stimulus (e.g., picture of a dog) and response prompt (e.g., teacher says, "dog"). After the student has responded correctly for several trials, the teacher inserts a delay between the instructional stimulus and the response prompt until the student emits the unprompted correct response. Time delay is considered an "errorless learning" technique because students often make few or no errors as control of responding shifts from the contrived prompt to the instructional stimulus.

Two variations of time delay are progressive time delay and constant time delay. A **progressive time delay** procedure starts with simultaneous presentation of the natural stimulus and the response prompt (i.e., 0-sec delay). Usually, a teacher will use several 0-sec trials before extending the time delay. The number of 0-sec trials will depend on the task difficulty and the functioning level of the participant. Following the simultaneous presentations, the teacher gradually and systematically extends the time delay, often in 1-sec intervals. With **constant time delay**, after the student has responded correctly to several 0-sec delay trials, presentation of the response prompt follows the instructional stimulus by a predetermined and fixed delay (usually 3 or 4 seconds) for all subsequent trials.

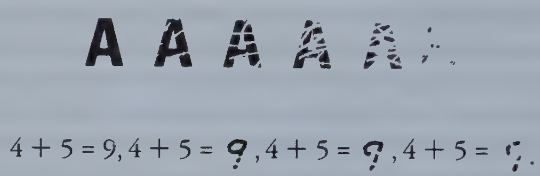
Time delay has been used to teach a variety of skills, such as sight word reading (Knight et al., 2003); spelling (Stevens & Schuster, 1987); numeral identification (Ault et al., 1988); and chained tasks such as food preparation, purchasing, vocational, and leisure skills (Dogoe & Banda, 2009). Time delay has been used effectively by peer tutors (Hughes & Fredrick, 2006) and parents (Dipipi-Hoy & Jitendra, 2004). Heckaman et al. (1998) reported that implementing progressive time delay immediately reduced rates of disruptive behavior associated with a task previously taught with least-to-most prompting procedure. For reviews of research on time delay, see Browder, Ahlgrim-Delzell, Spooner, Mims, and Baker (2009) and Dogoe and Banda (2009).

Transferring of Stimulus Control with Fading Techniques

The preceding sections focused on response prompts that do not change the task stimuli or materials. The stimulus control shaping procedures presented here modify the task stimuli or materials gradually and systematically to prompt correct responses. Supplementary stimulus conditions are faded in or faded out to transfer stimulus control from the stimulus prompt to the natural stimulus. Stimulus control shaping can be accomplished with stimulus fading and stimulus shape transformations (McIlvane & Dube, 1992; Sidman & Stoddard, 1967).

Stimulus Fading

Stimulus fading involves highlighting a physical dimension (e.g., color, size, position) of a stimulus to increase the likelihood of a correct response. The highlighted or exaggerated dimension is faded gradually in or out. The following examples of (a) writing the uppercase letter A and (b) writing the answer 9 to an arithmetic problem are illustrations of stimulus fading.



Krantz and McClannahan (1998) faded out scripts (i.e., the words *Look* and *Watch me*) embedded in photographic activity schedules. The embedded scripts prompted the social exchanges of children with autism. The words *Look* and *Watch me* were printed with 72-point font and bold letters on white 9-cm note cards. Krantz and McClannahan began fading out the words by removing one third of the script card, then another third. Sometimes, during the script fading, portions of letters were still shown on the card, such as part of an *o* in *Look*. Finally, the scripts and cards were removed.

The treatment of a feeding disorder reported by Patel, Piazza, Kelly, Ochsner, and Santana (2001) provides an example of fading stimuli in and out. Severe food selectivity is a common problem for children with feeding disorders. For example, some children find highly textured foods aversive because they evoke a gagging response. Patel and colleagues faded in Carnation Instant Breakfast (CIB) and then milk to water in treating a 6-year-old boy with pervasive developmental feeding disorder. The boy would drink small amounts of water. The researchers began the fading in procedure by adding 20% of the CIB packet to 240 ml of water. Following three sessions of drinking the 20% mixture, more CIB was gradually added to the water, initially by 5% and later 10% increments. The researchers then faded in milk to the CIB and water mixture after the boy would drink one CIB packet with 240 ml of water. Milk was gradually added to

the CIB/water mixture in 10% increments as the water was faded out (e.g., 10% milk and 90% water, plus one packet of CIB; then 20% milk and 80% water).

Applied behavior analysts have used the superimposition of stimuli with stimulus fading. In one instance, the transfer of stimulus control occurs when one stimulus is faded out; in another application, one stimulus is faded in as the other stimulus is faded out. The research by Terrace (1963a, b) demonstrating the transfer of stimulus control from a red–green discrimination to a vertical–horizontal discrimination shows the superimposition of two specific classes of stimuli and the fading out of one stimulus class. The lines were superimposed on the colored lights; then the lights were gradually faded out, leaving only the vertical and horizontal lines as the discriminative stimuli. Figure 17.6 provides an applied example of the superimposition and stimulus fading procedures used by Terrace. The figure shows a series of steps from an arithmetic program to teach 7 − 2 = _____.

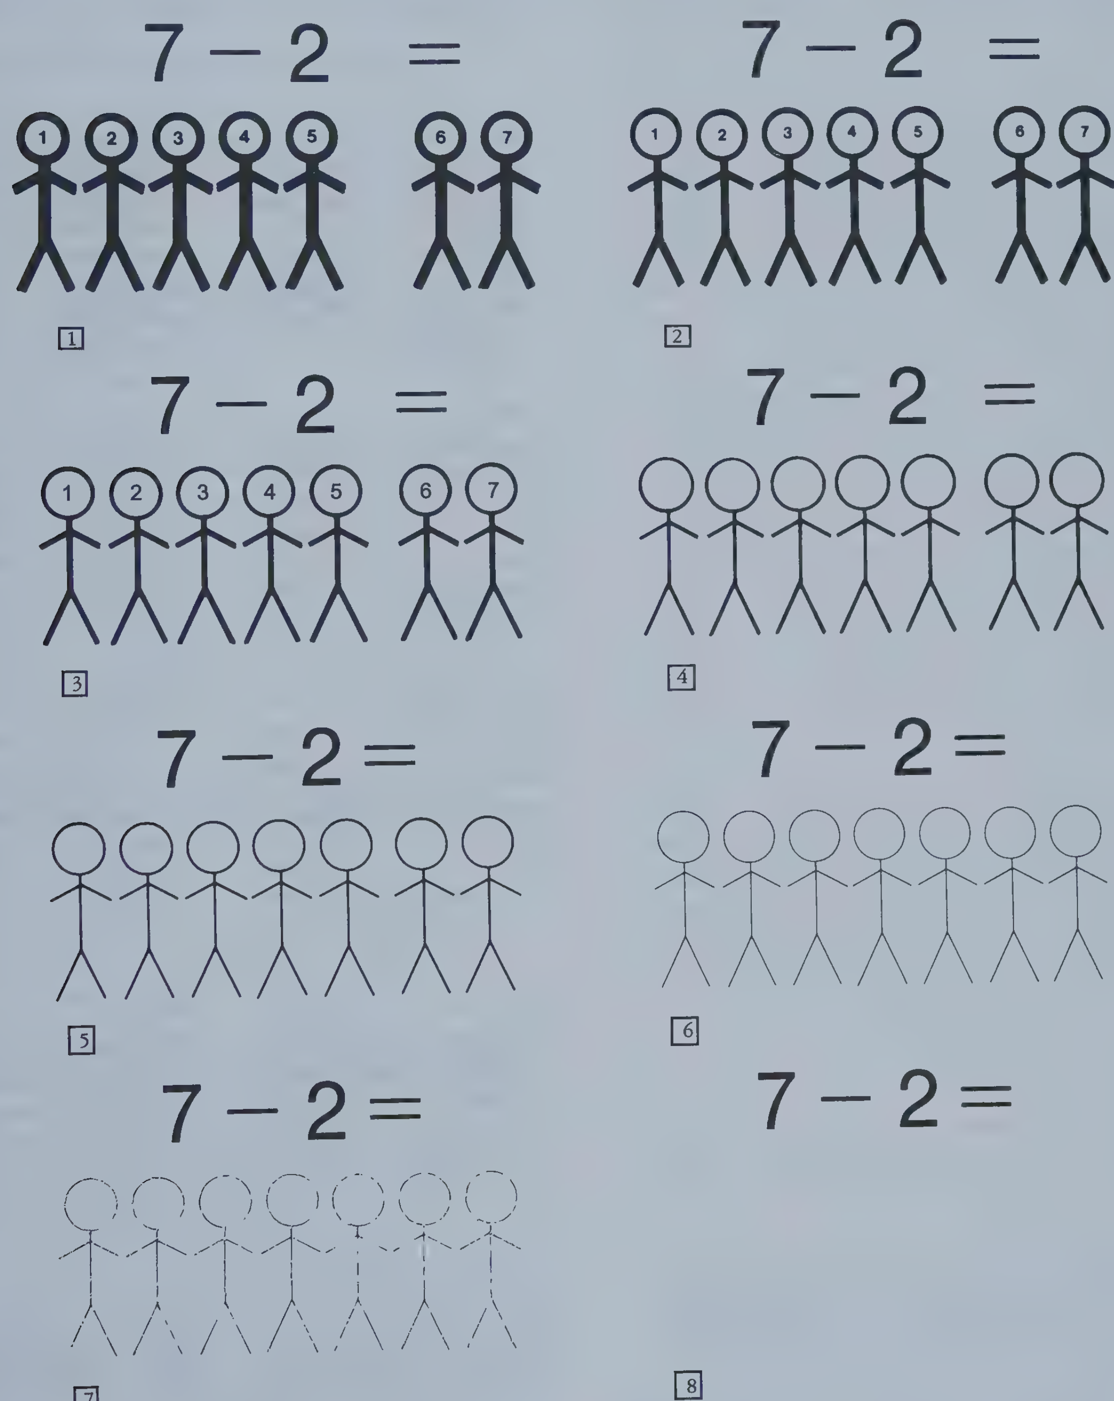


Figure 17.6 Illustration of two classes of superimposed stimuli with one class then faded out.
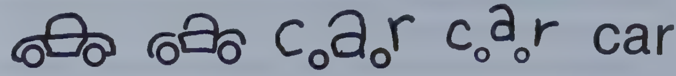
From *Addition and Subtraction Math Program with Stimulus Shaping and Stimulus Fading*, by T. Johnson, 1973, unpublished project, Ohio Department of Education. Reprinted by permission.

The other frequently used procedure fades in the natural stimulus and fades out the stimulus prompt. Figure 17.7 illustrates this superimposition procedure, in which the prompt is faded out and the natural stimulus 8 + 5 = _____ is faded in.

Stimulus Shape Transformations

The procedure for stimulus shape transformations uses an initial stimulus shape that will prompt a correct response. That initial shape is then gradually changed to form the natural stimulus, while maintaining correct responding. The shape of the stimulus prompt must change gradually so that the student continues to respond correctly. In teaching word identification, using stimulus shape transformations could include the following steps (Johnson, 1973):



In summary, a variety of procedures exist for transferring stimulus control from response and stimulus prompts to natural stimuli. Although fading, superimposition, and stimulus shaping procedures are often successful in transferring stimulus control, preparing the necessary stimulus materials for some tasks requires considerable time and technical skill, and may be costly. Practitioners should always consider the most effective and

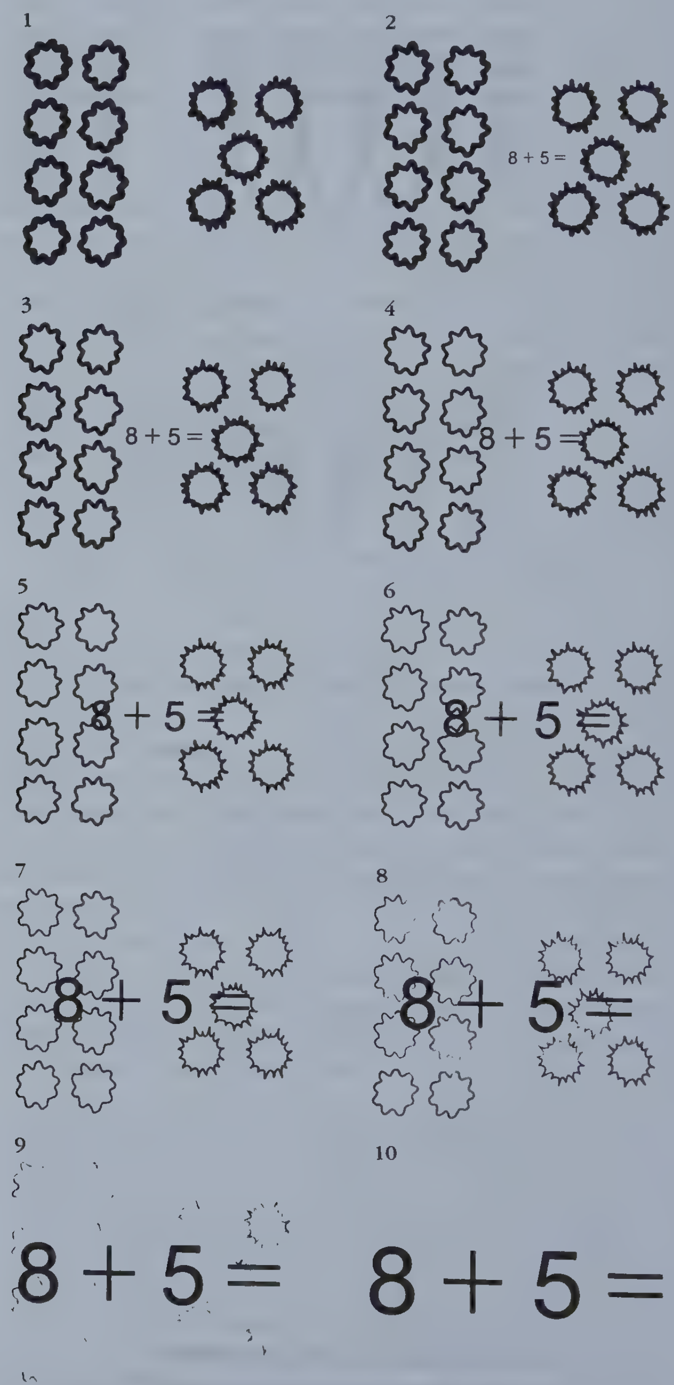


Figure 17.7 Illustration of superimposition and stimulus fading to fade in the natural stimulus and fade out the stimulus prompt.

efficient approach to changing behavior. A study related to binge drinking by college students is informative in this regard. Metz, Kohn, Schultz, and Bettencourt (2017) compared the effectiveness of three training procedures (stimulus fading, superimposition, and verbal feedback) on college students' pouring standard, 12-ounce servings of beer. Four of five participants in the stimulus fading group reached criterion (poured within 10% deviation of 12 oz) without additional training; three of four participants in the superimposition group required and received additional stimulus fading training. But three of four participants in the verbal-feedback-only group achieved criterion on their first set of posttraining pours. The authors concluded that "verbal feedback may be a relatively easy and effective method if used with actual pouring" (p. 29). We believe practitioners should keep in mind this adage: Just because you can do something doesn't mean you should, and always consider the simplest, most efficient methods of behavior change before designing and implementing a complex intervention.

SUMMARY

Stimulus Control: Basic Concepts and Processes

1. Behavior that occurs more often in the presence of a stimulus (discriminative stimulus, S^D) than in its absence (stimulus delta, S^Δ) is said to be under stimulus control.
2. When an S^D signals a rich schedule of reinforcement and a corresponding S^Δ signals a zero chance of reinforcement (i.e., extinction), the organism will eventually respond only in the presence of the S^D. In such cases, stimulus discrimination is complete.
3. Stimulus generalization refers to the extent to which stimuli other than the S^D acquire stimulus control over the behavior. Stimuli sharing similar physical properties with the S^D are most likely to acquire evocative function.
4. A stimulus generalization gradient graphically depicts the degree of stimulus generalization and discrimination by showing the extent to which responses reinforced in one stimulus condition are emitted in the presence of untrained stimuli.
5. Stimulus generalization reflects a loose degree of stimulus control, whereas discrimination indicates a relatively tight degree of stimulus control.
6. In a conditional discrimination, the response that will produce reinforcement in the presence of a particular stimulus depends on (is conditional on) the presence or absence of other stimuli.
7. An S^D acquires its controlling function for operant behavior by being paired with stimulus changes that occur immediately following behavior. Conversely, a conditioned stimulus acquires its controlling function for respondent behavior by being paired with other antecedent stimuli that elicit the behavior (i.e., an unconditioned stimulus or conditioned stimulus).
8. Distinguishing the evocative functions of discriminative stimuli and establishing operations can be difficult. An S^D evokes behavior because its presence has been correlated with the differential availability of an effective reinforcer. EO evokes behavior because it changes what functions as reinforcement rather than signaling the differential availability of reinforcement.

Developing Stimulus Control

9. Stimulus discrimination training entails reinforcing responses in the presence of the S^D and not reinforcing responses in the presence of the S^Δ.
10. Behavior analysts often teach and study conditional discriminations with a matching-to-sample procedure entailing a four-term contingency of observing response, the conditional sample, the discriminative events, and the comparison match.
11. A concept is defined by a set of shared features found in each example of the concept.
12. Concept formation is a complex example of stimulus control that requires both stimulus generalization within a class of stimuli and discrimination between stimulus classes.
13. An antecedent stimulus class is a set of stimuli that share a common relationship. All of the stimuli in the class will evoke the same operant response class, or elicit the same response in the case of respondent behavior.
14. Stimuli in a feature stimulus class share common physical forms (e.g., topographical structures) or common relative relations (e.g., spatial arrangements).
15. Stimuli composing an arbitrary stimulus class evoke the same response, but they do not share a common stimulus feature (i.e., they do not resemble each other in physical form, nor do they share a relational relationship).
16. Prompts are supplementary antecedent stimuli used to occasion a correct response in the presence of an S^D that will eventually control the behavior.
17. Response prompts (e.g., verbal instructions, modeling, physical guidance) operate directly on the response. Stimulus prompts (e.g., movement, position, redundancy) operate directly on antecedent task stimuli to cue a correct response in conjunction with the critical S^D.
18. Applied behavior analysts establish stimulus control with frequent differential reinforcement of behavior in the presence and absence of the S^D condition. Effective differential reinforcement requires the consistent use of consequences that function as reinforcers. Additional factors such as preattending skills, stimulus salience, overselective stimulus control, stimulus blocking, and overshadowing will also affect the development of stimulus control.

Transferring Stimulus Control

19. Terrace (1963a, b) conducted influential basic research using fading and superimposition of stimuli to transfer stimulus control.

20. Fading response prompts and stimulus prompts can transfer stimulus control from the prompts to the natural stimulus and minimize errors by the learner.

21. In the most-to-least response prompting procedure, the analyst physically guides the participant through the entire performance sequence and then gradually reduces the amount of physical assistance provided as training progresses from trial to trial and session to session.

22. Graduated guidance begins with the applied behavior analyst following the participant's movements closely with her hands, but not touching the participant. The analyst then increases the distance of her hands from the participant by gradually changing the location of the physical prompt.

23. With least-to-most prompting, the learner is given the opportunity to perform the response with the least amount of assistance on each trial. The teacher provides increasingly greater degrees of assistance with each successive trial, as needed.

24. Time delay procedures begin with simultaneous presentation of the target stimulus and response prompt. After the student has responded correctly for several trials, the teacher inserts a delay between the instructional stimulus and the response prompt.

25. Stimulus fading involves exaggerating a dimension of a stimulus to increase the likelihood of a correct response. The exaggerated dimension is faded gradually in or out.

26. Stimulus shape transformations begin with an initial stimulus shape that will prompt a correct response. The initial shape is then gradually changed to form the natural stimulus, while maintaining correct responding.

KEY TERMS

antecedent stimulus class
arbitrary stimulus class
concept
concept discrimination
constant time delay
discriminative stimulus (S^D)
errorless learning
feature stimulus class
least-to-most response prompts
most-to-least response prompts
overselective stimulus control
overshadowing
progressive time delay
response prompts
stimulus blocking
stimulus control
stimulus delta (S^Δ)
stimulus discrimination
stimulus discrimination training
stimulus fading
stimulus generalization
stimulus generalization gradient
stimulus prompts
time delay

MULTIPLE-CHOICE QUESTIONS

1. When a group of stimuli all evoke the same response (for example, when one sees a picture of a Border collie, a Doberman pinscher, and a Labrador retriever, one says "that's a dog"), the group of stimuli is referred to as:

a. A response class
b. A stimulus class
c. An arbitrary class
d. A response class

Hint: (See "Developing Stimulus Control")

2. Which of the following is an example of an arbitrary stimulus class?

a. The following women's restroom signs: the word woman, a pictogram of a woman, and a painting of a mermaid
b. A picture of a brick house, a stick built house, and a log cabin
c. A picture of a chair with no arms, a chair with arms, and a rocking chair
d. A picture of a bus, a car, and a motorcycle

Hint: (See "Developing Stimulus Control")

3. Which of the following illustrates an example of stimulus control?

a. Joanne occasionally runs the stop sign near her house because there are rarely any cars at the intersection
b. Frank flaps his hands almost constantly all day long.
c. Joe hits his teacher every time and only when she asks him to wash his hands.
d. Molly uses a Kleenex to wipe her nose when it is running and often when it is not running. It is a bad habit she has.

Hint: (See "Introduction to the chapter")

4. Which of the following statements is true?
   a. When a dog has been trained to salivate when a bell rings by repeatedly pairing meat powder and a bell, this is an example of stimulus control.
   b. When an individual has been trained to say the word "red" when he is shown a card that says RED (but not when he has been shown a card that says GREEN), this is an example of stimulus control.
   c. Antecedent stimuli rarely acquire control over human behavior.
   d. The first two statements are true.

   Hint: (See "Respondent Eliciting and Operant Discriminative Functions of Antecedent Stimuli")

5. A teacher makes a request of a student. The student emits aggressive behavior immediately following the request. The teacher removes the request in order to avoid getting hit. The teacher's request:
   a. Was clearly inappropriate
   b. Is a discriminative stimulus for the problem behavior
   c. Is a motivating operation for the problem behavior
   d. Is a stimulus delta for problem behavior

   Hint: (See "Respondent Eliciting and Operant Discriminative Functions of Antecedent Stimuli")

6. Motivating operations and discriminative stimuli:
   a. Have similar evocative effects on behavior
   b. Are considered synonymous
   c. Occur after the behavior of interest
   d. All of these

   Hint: (See "Discriminative and Motivational Functions of Antecedent Stimuli")

7. Amanda, a typically developing two-year-old girl, has a father who is in the Marines. The last time her father was home, he was in uniform. Now, every time she sees a man in uniform, she says, "Daddy!" This is an example of:
   a. Stimulus control
   b. Stimulus equivalence
   c. A response class
   d. Stimulus generalization

   Hint: (See "Stimulus Generalization")

8. Stimulus generalization is more likely to occur:
   a. When stimuli share more similar properties than when stimuli are very different from one another.
   b. When the practitioner tightly controls the training procedures and stimuli used during training (i.e., using few different stimuli during training).
   c. If time delay is used as part of the training procedure.
   d. If reflexivity is observed.

   Hint: (See "Stimulus Generalization")

9. Stimulus discrimination is acquired by:
   a. Reinforcing responses in the presence of a stimulus delta and withholding reinforcement in the presence of the discriminative stimulus.
   b. Reinforcing responses in the presence of both discriminative stimuli and stimulus deltas.
   c. Reinforcing responses in the presence of the discriminative stimulus and withholding reinforcement in the presence of the stimulus deltas.
   d. Thinning reinforcement so that no reinforcement is required for any antecedent stimuli.

   Hint: (See "Developing Stimulus Control")

10. Stimulus discrimination involves the behavioral principles of:
    a. Prompts and extinction
    b. Reinforcement and extinction
    c. Form and function of behavior
    d. Concepts and stimulus equivalence

    Hint: (See "Developing Stimulus Control")

11. In order to form the concept of "vehicles," an individual must be able to:
    a. Have an IQ of at least 100
    b. Have a strong grasp of concrete operations first
    c. Discriminate vehicles from nonvehicles and generalize across all motorized methods of transporting people
    d. Discriminate vehicles from nonvehicles

    Hint: (See "Developing Stimulus Control")

12. Which of the following is a concept that can be taught using stimulus discrimination and generalization procedures?
    a. Fruit
    b. Under
    c. Integrity
    d. All of these

    Hint: (See "Developing Stimulus Control")

13. The difference between a response prompt and a stimulus prompt is:
    a. A response prompt operates directly on the response, while a stimulus prompt operates on the antecedent task stimuli.
    b. Stimulus prompts are easier to fade than response prompts.
    c. A response prompt involves changing the required response, while a stimulus prompt requires changing the antecedent task stimuli.
    d. Response prompts are verbal, while stimulus prompts are nonverbal.

    Hint: (See "Using Response and Stimulus Prompts")

14. Rahul keeps forgetting to push the Total button on the cash register at his place of employment. His job coach wants to insert a prompt to help him remember to total customers' orders. She wants to use a stimulus prompt. Which of the following is an example of a stimulus prompt?
    a. When Rahul reaches the end of the order, the job coach gives him a nudge on the elbow to get his hand moving toward the Total button.
    b. When Rahul reaches the end of the order, the job coach says, "Don't forget to push Total."
    c. The job coach places a sign on the cash register that says "Don't forget to push Total."
    d. The job coach places a bright pink sticker on the total button.
    Hint: (See "Using Response and Stimulus Prompts")

15. Stimulus and response prompt fading is used to:
    a. Transfer stimulus control from the prompt to the natural antecedent cue.
    b. Thin the reinforcement schedule for responding correctly.
    c. Establish stimulus equivalence.
    d. Promote stimulus generalization.
    Hint: (See "Transferring Stimulus Control")

16. Most-to-least prompt fading involves:
    a. Gradually decreasing the time between the presence of the antecedent cue to the prompt from most time to least time.
    b. Gradually changing the form or intensity of the prompt from most intense to least intense.
    c. Gradually decreasing exaggerated dimensions of the stimulus prompt.
    d. Gradually changing the shape of the prompt to look more like the natural antecedent cue.
    Hint: (See "Transferring Stimulus Control")

ESSAY-TYPE QUESTIONS

1. Explain the basic teaching procedure for helping develop a stimulus class.
   Hint: (See "Developing Stimulus Control")

2. By what mechanisms do antecedents acquire control over respondent and operant behaviors?
   Hint: (See "Respondent Eliciting and Operant Discriminative Functions of Antecedent Stimuli")

3. Brian hits his teacher when he is asked to brush his teeth. However, he never hits his mother when she asks him to brush his teeth. His mother used to have this problem (of Brian hitting her), but she ignored it and made him continue brushing his teeth. His teacher, however, gets frustrated when Brian hits her and usually lets him out of the toothbrushing task (because she thinks it is not her job to get beaten up over doing a task that his parents should have responsibility for anyway). In this scenario, what is the discriminative stimulus and what is the motivating operation for Brian's hitting?
   Hint: (See "Discriminative and Motivational Functions of Antecedent Stimuli")

4. Compare and contrast stimulus generalization and stimulus discrimination.
   Hint: (See "Stimulus Generalization")

5. Explain (or use diagrams to illustrate) how you could teach an individual to say "ball" in the presence of balls, but not in the presence of other stimuli (say bats, blocks, paper).
   Hint: (See "Developing Stimulus Control")

6. Give an example of a concept and delineate what stimuli a learner might need to generalize across and what stimuli the learner might need to discriminate.
   Hint: (See "Developing Stimulus Control")

7. Swapna often forgets to pick up her dirty clothes in the morning and to put them in the clothes hamper. Give an example of each type of response prompt you could use to get her to put her clothes in the hamper. Also, give an example of how you could use stimulus prompts to help her.
   Hint: (See "Using Response and Stimulus Prompts")

8. Give an example of how you could use stimulus fading to help a learner draw a circle.
   Hint: (See "Transferring Stimulus Control")

PART 7

Verbal Behavior

Chapter 18 is devoted to a distinguishing feature of the human behavioral repertoire. Verbal behavior is the principal phenomenon that makes humans interesting and the vehicle with which we express that interest. Verbal behavior makes progress possible from one generation to the next and enhances the development of sciences, technologies, literatures, and the arts. Building on Skinner's (1957) conceptual analysis, Mark Sundberg presents verbal behavior within the context of typical human development, emphasizing the form and function of language, the defining characteristics of verbal behavior, the distinction between topography-based and selection-based verbal behavior, elementary verbal operants and listener discriminations, private events, generative verbal learning, and assessment and intervention programs for children with developmental disabilities.

CHAPTER 18

Verbal Behavior

Mark L. Sundberg

LEARNING OBJECTIVES

- Differentiate between formal properties and functional properties of language.
- Define verbal behavior.
- Define a verbal operant.
- Explain why Skinner suggested that the listener's role is less significant than typically assumed.
- Using a given example, determine the classification of verbal operants and explain how these terms can be used in the analysis of complex verbal behavior.
- Identify and discuss three or more functional units of verbal behavior that contribute to our understanding of multiple control.
- Define an autoclitic relation.
- Identify and discuss how viewing language as a learned behavior involving a social interaction between speakers and listeners, with the verbal operants as the basic units, changes how clinicians and researchers approach and ameliorate human problems related to language.

Jason was a 5-year-old boy diagnosed with autism. He could not talk, echo sounds, or imitate actions. He often screamed to get his needs and wants known. The immediate priorities were to teach Jason to communicate and to reduce his screaming behavior. Jason liked a variety of foods and toys and was taught to ask for them using sign language. He learned his first prompt-free sign ("apple") within 10 minutes of intensive teaching, and his second sign ("Play-Doh") about an hour later. In addition, his screaming behavior was reduced to a near-zero level during that first teaching session. After 4 months of intervention, Jason acquired 43 signs, learned to echo and imitate others, and began to speak. Within 2 years Jason could vocally identify over 300 items and actions, and his problem behaviors were minimal. The intervention program used with Jason was based on applied behavior analysis and Skinner's (1957) analysis of verbal behavior.

This chapter contains two major sections. The first describes the core elements of Skinner's (1957) analysis of verbal behavior, and the second describes some applications of that analysis to language assessment and intervention for persons with autism or other intellectual disabilities.

The author thanks Dave Palmer, Bob Ryan, Hank Schlinger, Carl Sundberg, and Cindy Sundberg for their comments on an earlier version of this chapter.

SKINNER'S (1957) ANALYSIS OF VERBAL BEHAVIOR

B. F. Skinner spent over two decades developing his analysis of language. He began the project a few years after graduating from Harvard University in 1931 and finished it in 1957. His main premise was that language constitutes learned behavior acquired and maintained by environmental contingencies. Reflecting on his work on language, Skinner (1978) wrote "*Verbal behavior* . . . will, I believe, prove to be . . . my most important work" (p. 122). Skinner considered language an important topic because verbal behavior is central to many critical aspects of human behavior (e.g., language acquisition, relationships, intelligence, academics).

It has been said that *Verbal Behavior* (1957) is Skinner's most difficult book to understand. Michael (1984) noted that a reader must first understand the basic concepts and principles of behavior analysis before taking on *Verbal Behavior*. However, a more problematic obstacle noted by Michael was the complexity of the subject matter being analyzed. Linguists have tangled with understanding human communication for centuries. Skinner's work can contribute to their efforts in many ways, beginning with a behavioral distinction between linguistic form and linguistic function.

Form and Function of Language

The formal properties of language involve the topography of a verbal response, and the functional properties involve the causes of that response. For example, a child's cry could be the form of verbal response, and why she cried would be the function.

Skinner's (1957) account of language considers both of these elements but differs from traditional treatments in that he provides a behavioral analysis of the functional properties. He identifies the distinction between form and function early in his book:

> Our first responsibility is simple *description*: what is the topography of this subdivision of human behavior? Once that question has been answered in at least a preliminary fashion we may advance to the stage called *explanation*: what conditions are relevant to the occurrences of the behavior—what are the variables of which it is a function? (p. 10).

Form

To account for both form and function, two separate but interlocking classification systems are necessary. The formal properties of language can be classified by a description of the verbal utterances emitted (e.g., speech, sign language, text, icons). For example, with speech it is common to measure the topography of what was said by (1) *phonemes*: the individual speech sounds that compose a word; (2) *morphemes*: the units with an individual piece of meaning; (3) *lexicon*: the total collection of words that make up a given language; (4) *syntax*: the organization of words, phrases, or clauses in sentences; and (5) *grammar*: the adherence to established conventions of a given language. The formal description of language also involves the classification of words by their grammatical forms or parts of speech, specifically, nouns, verbs, adjectives, adverbs, prepositions, determiners, conjunctions, and interjections (Barry, 1998; Brinton & Brinton, 2010). The traditional classification system is based on vocal response forms; thus certain adjustments are necessary for accommodating nonvocal response forms. For example, sign language involves *cheremes* rather than phonemes (Stokoe, Casterline, & Croneberg, 1965), and selection-based icon systems (e.g., iPad communication devices) have no clear parallel to phonemes.

Function

The second type of classification system involves the different functions that a word may have. For example, the same word (e.g., *book*) can have different meanings (e.g., something to read versus making a hotel reservation). Skinner suggests that the meaning of a word is not to be found in the form of a response, a cognitive processing system, a physical referent, structural regularity, or a person's genetic endowment, but rather in the immediate and historical environmental contingencies that evoke and consequate speaker and listener behavior. The primary purpose of his book *Verbal Behavior* was to identify those environmental contingencies.

Defining Verbal Behavior

Identifying exactly what constitutes language has eluded linguists for centuries. Skinner (1957) argued that what is commonly referred to as communication and language is learned speaker and listener behavior that is acquired, maintained, and extended by the same types of environmental variables that control nonverbal behavior (e.g., reinforcement, stimulus control, motivating operations). Skinner preferred the term *verbal behavior* over the term *language* because verbal behavior emphasizes the individual speakers and listeners rather than the practices of whole verbal communities (e.g., the English *language*).

In defining verbal behavior, Skinner (1957) placed the focus on an analysis of the immediate and historical contingencies that affect speakers and listeners. Accordingly, he defined **verbal behavior** "as behavior reinforced through the mediation of other persons" (p. 2), but these other persons "must be responding in ways which have been conditioned *precisely in order to reinforce the behavior of the speaker"* (p. 225). For example, if a parent asks a child, "Can you let the cat out?" the behavior of the child (listener) is necessary to produce an open door; thus, the receipt of the reinforcer is mediated by the behavior of the child (the listener). But the child must have a training history to successfully mediate reinforcement in this way (e.g., the child understands his[1] parent's words). Nonverbal behavior could produce the same reinforcer by the parent opening the door herself, but the reinforcement for this behavior is not mediated through another person.

Skinner's definition of verbal behavior was not meant to solve the linguist's query regarding the beginnings of "true" language (e.g., Hayes, Barnes-Holmes, & Roche, 2001; Hockett, 1960; Malott, 2003; Normand, 2009; Palmer, 2004). Michael (in Michael & Malott, 2003) noted that "Skinner's definition of verbal behavior . . . is only intended to identify [that] the topic of his consideration in the book on verbal behavior . . . can be narrowed to what is traditionally recognized as the verbal field" (p. 116). By treating language as behavior emitted by speakers and listeners, the focus of the analysis and its applications is on the contingencies responsible for that behavior.[2]

Speaker and Listener

The behaviors of a speaker and a listener are controlled by different but interlocking contingencies. These contingencies and the behaviors they establish and evoke are simple at first, but rapidly grow to enormous complexity. Skinner (1957) provides separate accounts of speaker and listener behavior and terms their interactions *verbal episodes* (p. 38). In a **verbal episode**, a **speaker** emits any type of verbal response in any form (speech, sign language, eye contact), and a **listener** (1) serves as an audience for a speaker, (2) provides reinforcement for a speaker, and (3) responds in specific ways to the speaker's verbal behavior. The roles of speaker and listener alternate in an exchange, and usually involve covert speaker and listener behavior as well. These speaker and listener repertoires will be defined, exemplified, and elaborated on throughout this chapter. However, it is valuable to first make a distinction between verbal responses based on response form and those based on stimulus selection.

Topography-based and Selection-based Verbal Behavior

Verbal behavior is not restricted to spoken words. Any form of operant behavior can acquire a verbal function (e.g., sign language, fingerspelling, icon selection, Braille, facial expressions, intonation). Skinner's broader view of linguistic response

forms expands the options for nonvocal persons in need of augmentative and alternative communication (AAC). In an effort to provide clarity to the issue of verbal response forms, Michael (1985) suggested that a distinction be made between topography-based verbal behavior (e.g., speech, sign language, text) and selection-based verbal behavior (e.g., tablet-based icon-selection programs, Picture Exchange Communication System [PECS], voice output devices).

Michael (1985) states that in **topography-based (TB) verbal behavior** "[t]he *unit of verbal behavior* can be described as an increased strength of a distinguishable topography given some specific controlling variable" (p. 1). This category of verbal behavior can include speech, sign language, writing, fingerspelling, and other response forms in which the listener is affected by a speaker's specific response topography. For example, if a child wants to play with an iPad and signs iPad, that response form informs the listener of the relevant motivation, allowing for the delivery of specific reinforcement (the iPad). Had the child signed "cookie," that topography would inform the listener that a different motivator and consequence are involved.

In **selection-based (SB) verbal behavior**, Michael (1985) states that "the *unit of verbal behavior* can be described as an increased control of the pointing [or selecting] response by a particular stimulus as a result of a different stimulus . . . or establishing operation" (p. 1). For example, the same "iPad," request exemplified above could also occur by selecting the iPad icon from a comparison array. The selected icon also informs the listener of the relevant motivation and allows for the delivery of specific reinforcement. In SB verbal behavior, what is conveyed to the listener is the information on the stimulus selected, as opposed to TB verbal behavior, where the listener's behavior is controlled by the topography of a speaker's response.

Michael's distinction between TB and SB verbal behavior has provided valuable conceptual and practical guidance for understanding a number of important behavioral issues (for a review, see Shafer, 1993). For example, the distinction can facilitate the selection and implementation of AAC systems for children with severe language delays (e.g., Charlop-Christy, Carpenter, Le, LeBlanc, & Kellet, 2002; Frost & Bondy, 1994; McGreevy, Fry, & Cornwall, 2012; Sundberg, 1993a; Tincani, 2004). In addition, research shows that TB systems may produce types of generative learning as observed in stimulus equivalence and relational framing more efficiently than SB systems (Jennings & Miguel, 2017; Lowenkron, 1998; Pérez-González, Salameh, & García-Asenjo, 2018; Polson & Parsons, 2000; C. T. Sundberg & Sundberg, 1990; C. T. Sundberg, Sundberg, & Michael, 2018; Wraikat, C. T. Sundberg, & Michael, 1991).

Behavioral Cusps

When an infant learns to walk, it changes her life forever. Once standing and walking occur, new stimuli, motivators, and reinforcers are available and they immediately begin to evoke and shape new behaviors. Rosales-Ruiz and Baer (1997) termed these significant human developmental changes *behavioral cusps*, and defined them as "any behavior change that brings the organism's behavior into contact with new contingencies that have even more far-reaching consequences" (p. 533). A cusp represents the beginning of a new level of learning for a child. Rosales-Ruiz and Baer (1997) elaborate on their definition by noting, "What makes a behavior change a cusp is that it exposes the individual's repertoire to new environments, especially new reinforcers and punishers, new contingencies, new responses, new stimulus controls and new communities of maintaining or destructive contingencies. When some or all of those events happen the individual's repertoire expands . . . and perhaps that leads to some further cusps" (p. 534).

There are many types of cusps; some are minor, but some are especially important for human development because their far-reaching learning effects can change the course of a child's development. Some of a child's most important early cusps involve motor behavior (e.g., a pincer grasp, crawling, walking), social behavior (e.g., joint attention, adults as conditioned reinforcers), and language acquisition (e.g., imitating, echoing, listening, manding) (Bosch & Fuqua, 2001; Bosch & Hixson, 2004; Greer & Ross; 2008; Hixson, 2004; Hixson, Reynolds, Bradley-Johnson, & Johnson, 2010; Rosales-Ruiz & Baer, 1997; Staats, 1996).

It is important to distinguish between the acquisition of a cusp and the facilitative effects of the cusp itself. In acquisition, the elements of a cusp are gradually established, but the new consequences produced by the cusp only become available when the cusp is achieved. For example, approximations to crawling are gradually shaped, but only when crawling is successful does its far-reaching consequences begin to affect an infant's behavior in a more powerful way (e.g., the automatic reinforcement obtained by crawling to a different room). Cusps can be valuable to a child, especially when they are combined with other cusps and produce even more generative cusps (Greer & Ross, 2008; Hixson et al., 2010; Michael, Palmer, & Sundberg, 2011; Rosales-Ruiz & Baer, 1997). For example, once a child can emit echoic, tact, listener, and self-listener behaviors, new mands and tacts can be acquired incidentally with no formal training or reinforcement history (Horne & Lowe, 1996; Pérez-González, Pastor, & Carnerero, 2014).

The Elementary Verbal Operants and Listener Discriminations

A behavioral analysis of expressive and receptive language involves identification of the antecedents and consequences that control the different types of speaker and listener behavior. Skinner (1957) identified three *separate* sources of antecedent control for speaker behavior: (1) motivating variables, (2) nonverbal discriminative stimuli (S^Ds), and (3) verbal S^Ds. These three sources of antecedent control and their related history of consequences provide the framework for distinguishing between five different types of expressive language (duplic, mand, tact, intraverbal, codic). Michael (1982) termed these basic components of Skinner's taxonomy the **elementary verbal operants**. Receptive language involves the behavior of the listener, and can be behaviorally characterized as mainly nonverbal listener discriminations controlled by verbal S^Ds (e.g., a teacher says, "touch the red balloon" and the child touches the red balloon, not the blue one). However, much of

Figure 18.1 The elementary verbal operants and listener discriminations.

SPEAKER REPERTOIRES (Expressive Language)		
Antecedent Variables	**Behavior**	**Listener-mediated Consequences**
Motivating operation (value of being pushed is high)	*Mand* (saying "push")	Specific reinforcement (being pushed)
Nonverbal S^D (seeing snow)	*Tact* (saying "snow")	Generalized S^r (e.g., praise, approval)
Verbal S^D with formal similarity to the response (hearing "bear")	*Duplic (echoic, motor imitation, copying text)* (saying "bear")	Generalized S^r
Verbal S^D with *no* formal similarity, but with point-to-point correspondence (seeing "dog" written or hearing "dog")	*Codic (textual, taking dictation)* (saying "dog" or spelling "dog")	Generalized S^r
Verbal S^D *without* point-to-point correspondence (hearing "What time?")	*Intraverbal* (saying "10 AM")	Generalized S^r

LISTENER DISCRIMINATION (Receptive Language)		
Antecedent Variables	**Behavior**	**Consequence**
Verbal S^D and a nonverbal S^D ("Give me a pen" along with the pen)	Nonverbal operant behavior (listener hands the speaker a pen)	Generalized S^r

a listener's behavior is also verbal (e.g., covert self-talk) and should be treated as verbal behavior (Schlinger, 2008a). The elementary verbal operants and listener discriminations will be briefly defined and exemplified below and in Figure 18.1, followed by a more in-depth treatment of each type of speaker and listener repertoire.

Mand

When a person asks for something to drink, for directions to a post office, or to be left alone, she is usually manding. Mands allow a speaker to get her needs and wants known to a listener. The **mand** relation is a type of verbal behavior in which the form of a response (words, signs, gestures, icon exchanges, etc.) is under the functional control of a motivating operation (MO) and a history of specific reinforcement (Figure 18.1). For example, a mand can be observed when a child wants to be pushed on a swing and emits the word "push" and an adult then pushes her on the swing. The reinforcement for a mand is specific to the MO; that is, being pushed by adults is what the child wants, not just claps and cheers.

Tact

When a child names her friends in the room while looking at them, she is usually tacting. Tacts involve a speaker's ability to verbally identify aspects of the physical environment. The **tact** relation (Figure 18.1) is a type of verbal behavior in which the form of a response is under the functional control of a nonverbal discriminative stimulus (S^D) and a history of conditioned reinforcement (S^r) (e.g., seeing snow and saying "snow").

Duplic

There are three types of **duplic** relations: echoic, motor imitation, and copying text. They all have the same defining features but have unique topographical features. Repeating spoken words exemplifies the echoic, imitating sign language exemplifies motor imitation, and copying written words exemplifies copying text.

Duplic: Echoic. The **echoic** relation (Figure 18.1) is a type of duplic verbal behavior in which the form of a vocal response is under the functional control of an auditory verbal S^D that has formal similarity between the stimulus and the response product, and has a history of generalized S^r (Figure 18.1). **Formal similarity** occurs when the controlling verbal stimulus and the response product are in the same sense mode (e.g., both are auditory), and the stimulus and the response product resemble each other in the physical sense of resemblance (e.g., hear "bear," say "bear").

Duplic: Motor Imitation. **Motor imitation** (relating to sign language) (Figure 18.1) is a type of duplic verbal behavior in which the form of a motor response is under the functional control of a visual verbal S^D that has formal similarity and a history of generalized S^r (e.g., parent signs "car" and the child signs "car").

Duplic: Copying Text. Writing letters and words that match other letters and words constitutes copying text (fingerspelling and Braille can also be copied). Copying textual stimuli has the same defining features as echoic and motor imitation, except the response form is written, fingerspelled, or Braille punched. **Copying text** (Figure 18.1) is a type of verbal behavior in which the form of a transcriptive response is under the functional control of a textual verbal S^D that has formal similarity and a history of generalized S^r (e.g., writing down an address observed on a website).

Codic

There are two types of **codic** relations: textual and taking dictation. Textual behavior for speech is emitting vocal

responses controlled by written verbal S^Ds, while taking dictation is emitting transcriptive and spelling behaviors controlled by vocal verbal S^Ds. Similar codic relations can occur with sign language and Braille.

Codic: Textual. The **textual** relation (Figure 18.1) is a type of verbal behavior in which the form of a response is under the functional control of a verbal S^D and a history of generalized S^r, but has *no* formal similarity between the stimulus and the response product. However, there is a broader type of match between the verbal stimulus and the verbal response that Skinner terms *point-to-point correspondence*. **Point-to-point correspondence** occurs when the parts of a verbal stimulus correspond to the parts of a verbal response but do not physically match each other (e.g., see "D-O-G," then saying "dog").

Codic: Taking Dictation. When someone gives you a name and you write it down, you convert spoken words to written words (spelling). Although somewhat dated, but nonetheless accurate, Skinner's term **taking dictation** (Figure 18.1) describes this type of verbal behavior, in which the form of a response is under the functional control of a verbal S^D with point-to-point correspondence between the verbal stimulus and the verbal response product, and a history of generalized S^r, but has no formal similarity (e.g., hearing "dog," then typing "D-O-G").

Intraverbal

Answering questions, telling stories, and recalling memories are usually intraverbal behaviors. Our intraverbal repertoires allow us to verbally respond to verbal stimuli we encounter or produce ourselves. The **intraverbal** relation (Figure 18.1) is a type of verbal behavior in which the form of a response is under the functional control of a verbal S^D that does *not* have point-to-point correspondence with the verbal stimulus (e.g., receiving the text "What time?" and texting back "10AM"). There is also a relevant history of generalized S^r involved.

Listener Discriminations

An important component of language involves a listener's ability to discriminate between verbal stimuli emitted by speakers, and to act upon those stimuli, even when the speaker and listener are the same person. Listener discriminations are commonly referred to as receptive language. **Listener discriminations** (Figure 18.1) can be defined as a verbal S^D that evokes a corresponding nonverbal response (or class of responses) due to a history of generalized S^r (e.g., someone asks for a pen and you reach for a pen).

Matching-to-Sample (MTS)

MTS procedures teach a child to attend to and organize the various stimuli that affect his sensory systems (e.g., sights, sounds, tastes). A generalized matching repertoire (e.g., placing novel pictures of various exemplars of a category together) can facilitate the establishment of equivalent and nonequivalent relations between various classes of stimulus events (Chapters 19 and 20). Matching skills are valuable in language instruction for severely language-delayed children and adults. For example, a child who can match pictures of dogs, and discriminate them from other animals, and then learns to call one of the pictures a "dog," may be able to correctly tact novel pictures of a dog, without further training.

Classifying the Verbal Operants

An important component of making use of Skinner's analysis of verbal behavior is the ability to classify a verbal response as a mand, tact, intraverbal, and so on. Classifying the verbal relations allows us to more precisely identify, organize, and account for the specific variables that might control a given utterance. Classification can also assist in identifying fine distinctions between variables that may prove to be of interpretive or clinical value (Palmer, 2016). Figure 18.2 presents a flow chart that can be used to narrow down the sources of control for a sample of verbal behavior. Verbal classification can be accomplished by asking the following questions regarding possible controlling variables for a target response.

1. Does an MO control the response form? If yes, then the response is at least part mand.
2. Does an S^D control the response form? If yes, then:
3. Is the S^D nonverbal? If yes, then the response is at least part tact.
4. Is the S^D verbal? If yes, then:
5. Is there formal similarity between the verbal S^D and the response? If yes, then the response is duplic (echoic, imitative, or copying text). If not, then:
6. Is there point-to-point correspondence between the verbal S^D and the response? If yes, then the response is codic (textual or taking dictation). If not, then the response is at least part intraverbal.

THE VERBAL OPERANTS AND LISTENER BEHAVIOR IN MORE DETAIL

Motivating Operations and the Mand

Motivation is an important source of antecedent control of human behavior. Much of what we do each day is controlled by MOs (Chapter 16). Unlearned MOs, such as those related to food, water, warmth, and sleep, are straightforward and need to be accommodated each day. In contrast, learned MOs, such as those related to money, information, travel, relationships, and so on, are often more complicated in part due to their variability and uniqueness to each individual.

Both types of MOs can evoke nonverbal and verbal behaviors. In addition, their related histories of specific reinforcement can alter the functions of other MOs and S^Ds (Schlinger & Blakely, 1987, 1994). For example, on a hot day when a person is shopping and has not had anything to drink for a while, the value of water might gradually increase to the point where nonverbal behavior is evoked (e.g., looking for a drinking fountain). The history of specific reinforcement related to the MO can also alter the functional properties of other stimuli, such as establishing a drinking fountain as an S^D that immediately evokes approach behavior. If water is located and a sufficient amount is consumed, the value of water and its evocative strength weakens via satiation,

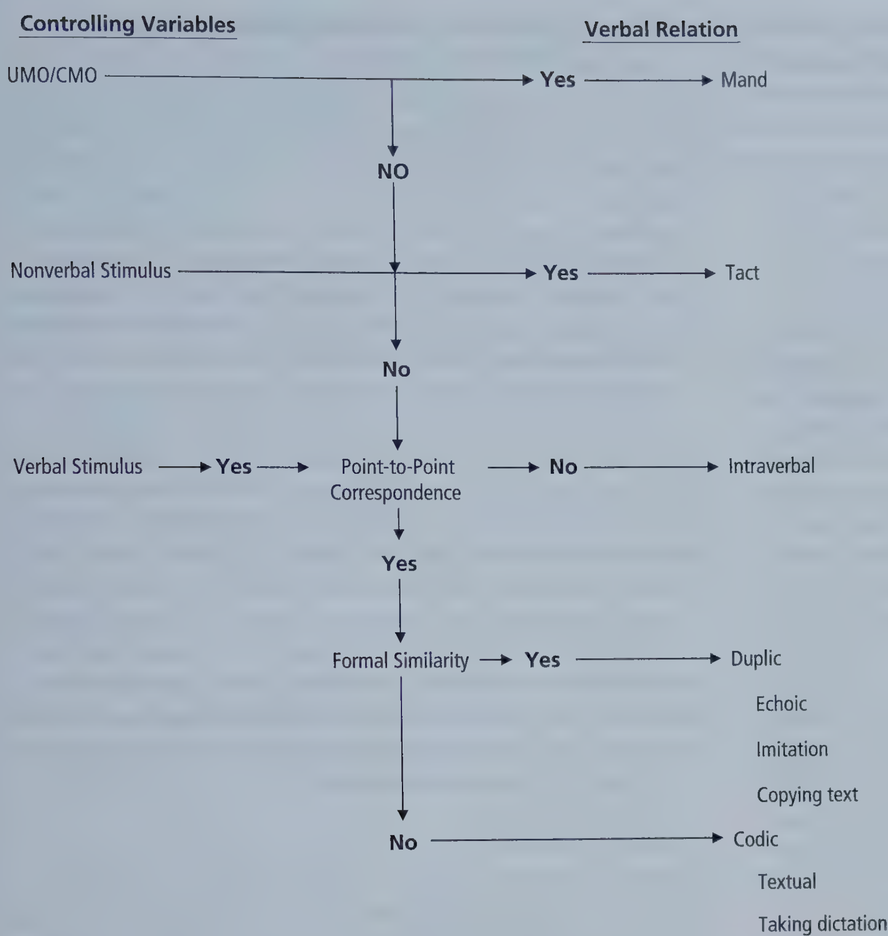

Figure 18.2 Verbal behavior classification chart.

thus an abolishing operation (AO), and the functional properties of the fountain change to an S^{Δ} (one stops searching for drinking fountains).

The same MO (water deprivation) can also evoke verbal behavior (e.g., asking for water), but a listener is necessary to mediate (deliver) the reinforcement, and to complete the verbal episode. In this case, a specific history of reinforcement from listeners alters the functional properties of MOs, as well as the functional properties of potential listeners, establishing some listeners as S^Ds for manding behavior (e.g., a waiter) and others as S^{Δ}. When the mand is successful, it results in the same specific reinforcement and AO achieved through nonverbal behavior that involves obtaining water, with the only difference being how the water was obtained. When MOs evoke a verbal response that produces specific reinforcement mediated by listeners, Skinner (1957) termed this verbal relation a *mand* (Figure 18.1).

Specific Reinforcement and the Mand

The defining consequences for the mand constitute what Skinner (1957) terms *specific reinforcement* (p. 56). Specific reinforcement involves reinforcement that is established by its relation to a specific MO (e.g., water deprivation establishes water as specific reinforcement). When sufficient specific reinforcement is provided, it abolishes the MO. For example, if there is an MO at strength for finding one's car keys, the specific reinforcement is locating the keys. This specific reinforcement also alters the function of any number of contextual stimuli (e.g., drawers become S^Ds for opening and searching behaviors). Finding the keys has multiple effects; it abolishes the MO and simultaneously functions as reinforcement, strengthening the particular behavior that was evoked by the MO (e.g., searching, manding). Specific reinforcement can be contrasted with generalized S^r characteristic of the other verbal operants. Generalized S^r acquires its strengthening effect by its relation to a variety of MOs and relevant reinforcement history, and, as a result, is not dependent on any single MO (Michael, 2004).

Classifying Mand Relations

Classifying the mand relation largely depends on talking precisely about its two defining features: (1) MOs and (2) specific reinforcement. Mands can be classified by identifying the different types of MOs that control manding behavior and by the different ways mands affect the behavior of the listener and produce specific reinforcement. Michael and colleagues (e.g., Laraway, Snycerski, Michael, & Poling, 2003; Michael, 1982, 1993, 2004; Chapter 16) distinguish between two main types of MOs: unconditioned motivating operations (UMOs) and conditioned motivating operations (CMOs). UMOs involve types of motivation that are innate to humans, and do not require a learning history to affect behavior, while CMOs are the direct result of a learning history. In general, a distinction could be made between (1) MOs related to deprivation

and specific reinforcement established by that deprivation, and (2) MOs related to the removal of aversive stimulation and the specific negative reinforcement related to that condition. There are different types of UMOs and CMOs that evoke mands, each of which has different behavioral effects (Chapter 16).

Mands Evoked by Unconditioned Motivating Operations (UMOs)

Michael and Miguel (Chapter 16) identified nine UMOs, six of which are related to deprivation (food, water, sleep, activity, oxygen, and sex) and three of which are related to aversive stimulation (the aversive conditions of becoming too hot, becoming too cold, and an increase in painful stimulation). Each of these MOs (e.g., sleep deprivation) can evoke learned nonverbal behavior (e.g., going to bed) and/or verbal behavior (e.g., a mand), and the specific reinforcement related to the MO can alter the functional effects of other variables as well (e.g., a sofa functions as an S^D evoking an approach response).

Deprivation-based UMOs. Some of an infant's first mands are evoked by unlearned deprivation (Bijou & Baer, 1965; Skinner, 1957). What begins as a human biological process soon becomes learned operant behavior. Food deprivation, for example, may initially elicit crying as a biological (respondent) event, but through the process of reinforcement (i.e., feeding the infant), crying becomes an operant (Bijou & Baer, 1965; Novak & Pelaez, 2004; Schlinger, 1995). Each of the different deprivation-based UMOs may initially evoke crying, but due to the effects of differential specific reinforcement, the response topographies begin to shift (e.g., a hunger cry sounds different from a tired cry). Parents are often able to discriminate between different forms of crying by about the 8th week of an infant's life (Brazelton & Sparrow, 2006). Eye contact can also serve a similar verbal function for an infant in that MOs and specific reinforcement can establish differential looking behavior that acquires a mand function (Isaksen & Holth, 2009).

Aversive Stimuli as UMOs. Three UMOs are related to unlearned aversive stimulation (too hot, too cold, and painful stimulation), and it is their removal that functions as specific negative reinforcement. Michael and Miguel (Chapter 16) explain that "painful stimulation establishes pain reduction as a reinforcer and evokes the (escape) behavior that has achieved such reduction" (p. 381). For example, if a child experiences a burn, the behavior evoked by this aversive UMO can be nonverbal (e.g., turning on a cold water faucet), or it can be verbal (e.g., "Mommy!"). Mands controlled by aversive stimulation also occur early in language development and, like mands related to deprivation, participate in many aspects of human development (e.g., language acquisition, bonding, intellectual development). Identifiable mands of any type are valuable to caregivers in that a recognized response form can help a caregiver identify a child's private MOs and the desired specific reinforcement. Thus, early manding allows reliable access to a child's inner world.

Mands Evoked by Conditioned Motivating Operations (CMOs)

CMOs are more varied than UMOs and can change frequently. Michael and Miguel (Chapter 16) define a CMO as "motivating variables that alter the reinforcing effectiveness of other stimuli, objects, or events, but only as a result of the organism's learning history" (p. 393). For example, a low battery notice on a phone increases the value of a power cord and evokes behavior that involves a history of obtaining that specific reinforcement. Michael and Miguel (Chapter 16) identify three types of CMOs: transitive (CMO-T), reflexive (CMO-R), and surrogate (CMO-S), each of which can evoke manding behavior.

Parts of Speech. Another way to classify some CMO effects is by the parts of speech. For example, a CMO-T related to nouns often involves a stimulus change (e.g., encountering a parking meter) that alters the value of objects (e.g., coins). Verbs often involve movement, and a stimulus change (e.g., being put in a wagon) can increase the value of an event (e.g., being pulled). Similar types of CMO-Ts can be identified for many adjectives, adverbs, prepositions, etc., as well as for verbal information, help, and so on. For those in need of language intervention, there are many ways in which these types of CMO-Ts can be captured or created for instructional purposes.[3]

Multiple Control

Any instance of human behavior is usually a function of multiple variables operating simultaneously. The task of the behavior analyst is to identify the relevant sources of control responsible for a behavior of concern, and Skinner's analysis of multiple control can be of help in this process. Skinner (1957) begins his treatment of **multiple control** by stating, "Two facts emerge from our survey of the basic functional relations in verbal behavior: (1) the strength of a single response may be, and usually is, a function of more than one variable and (2) a single variable usually affects more than one response" (p. 227). Michael et al. (2011) suggested that Skinner's two effects be termed (1) *convergent multiple control* and (2) *divergent multiple control*. In convergent multiple control, a single response is controlled by more than one antecedent variable. For example, a mand is usually controlled by both an MO (e.g., for information) and an S^D (e.g., an audience). In divergent multiple control, a single antecedent variable controls more than one response. For example, the verbal stimulus "Who was Darwin?" could evoke any number of different verbal responses from a listener turned speaker, such as "natural selection," "HMS Beagle," or "the Galapagos Islands."

Convergent Control Involving Multiple MOs. Multiple types of motivation can participate in any verbal episode. MOs can combine and enhance an evocative effect, or compete with each other for the control of behavior (e.g., Michael et al., 2011; Sundberg, 2013). For example, when MOs related to exercise and social interaction combine, they may evoke a mand like "Do you want to go to the gym?" MOs also commonly compete with each other. For example, an MO related to food deprivation and

social embarrassment may compete to evoke either "Yes, I'd like another piece of cake" or "No, thank you." This convergence of antecedent MO variables on behavior often produces emergent effects (both respondent and operant) quite different from the effects of each element of the compound arrangement operating independently.

Convergent Control Involving MOs and S^Ds. MOs typically participate with S^Ds in evoking our day-to-day behavior. As with multiple MOs, combining MOs with S^Ds can produce an additive or competitive effect on behavior. For example, early mand training for nonverbal children consists of combining echoic or imitative prompts with MOs and salient nonverbal stimuli. MOs and S^Ds can also compete with each other. For example, a parent may have strong instructional control over a child's behavior, except when he is playing video games. S^Ds can affect MO control as well, as when a verbal S^D (e.g., a question about sports) disrupts control by a current CMO-R (e.g., studying for an exam).

Mand Control. An MO may be insufficient to control behavior on its own, but when combined with other antecedents, the MO successfully participates in evoking behavior. For example, an MO regarding helping people may not evoke behavior until other stimuli, such as a person falling, are combined with the incipient MO. The weakness of an MO related to helping people could be demonstrated by seeing someone fall and not offering help. Palmer (2016) suggests that there are many circumstances in which the "antecedent is, by itself, insufficient to evoke the relevant response" (p. 100), but when combined with other variables it evokes behavior. In his discussion on intraverbal relations, Palmer suggests the term *intraverbal control* be used to identify this supplementary type of control as it relates to verbal S^Ds. A similar case could be made for *mand control* where an MO by itself is insufficient to evoke behavior, but, when combined with other variables, an evocative effect occurs.

Private Events

Most types of MOs are private; that is, only one person can experience their effects. Skinner (1953) termed these types of covert variables **private events** and stressed that despite their inaccessibility, private events cannot be neglected as causal variables in the interpretation of behavioral events (Skinner, 1945, 1953, 1974). Skinner (1953) explains: "With respect to each individual . . . a small part of the universe is *private*. We need not suppose that events which take place within an organism's skin have special properties for that reason. A private event may be distinguished by its limited accessibility but not, so far as we know, by any special structure or nature" (p. 257).

Many events occur within our bodies and affect how we behave. For example, verbal behavior can easily become covert. A speaker becomes her own listener and responds to her own verbal behavior much in the same way she responds to the verbal behavior of others (Horne & Lowe, 1996). We can and do talk to ourselves and it helps us solve problems, comprehend what others say, edit what we might say, recall past events, entertain ourselves, and so on. Although these private verbal events will always be inaccessible to others, under some circumstances they can be indirectly measured (Palmer, 2011).

Nine Types of Mands Distinguished by Listener Behavior

Skinner suggests that some mands can be classified by the differential mediating behavior of the listener and the reinforcement that strengthens that listener behavior. He offers nine types of mands (Figure 18.3): requests, commands, prayer, questions, advice, warning, permission, offer, and call. For example, in making the distinction between a request and a command, Skinner suggests that a request is emitted to a listener who is motivated to reinforce a speaker (e.g., a waiter). The specific reinforcement provided by the listener is the specific item requested, and reinforcement for the listener is some form of generalized S^r (e.g., "Thanks!"). A command, in contrast, involves an unwilling listener and the verbal stimulus needs to be supplemented with aversive stimuli. The specific reinforcement provided by the listener is compliance with the speaker's command. The listener is reinforced by the removal of the threat—thus a type of negative reinforcement. Skinner provides a similar treatment for the other types of mands he identified (Figure 18.3).

Emergent Mand Relations

Learning to mand is a powerful behavioral cusp in early child development (Bijou & Baer, 1965; Greer & Ross, 2008; Rosales-Ruiz & Baer, 1997; Sundberg & Michael, 2001). A child's mand repertoire typically grows quickly (due to MO and specific reinforcement effects) and often does so with little formal instruction. Once a child has acquired basic echoic, mand, tact, and listener repertoires, the combination of these cusps can produce emergent mands in a number of different ways. For example, once a child acquires mand frames (e.g., "I want_X_") and can tact objects and actions, new tacts can be inserted into the mand frame by direct training, incidental exposure, or relational framing (e.g., Hall & Sundberg, 1987; Horne & Lowe, 1996; Pérez-González, Pastor, & Carnerero, 2014; Rosales & Rehfeldt, 2007). A more advanced and quite generative mand cusp involves mands for information (e.g., "What's that?" "Where's Mommy?"). A child's ability to ask questions plays a major role in vocabulary growth by generating new tacts, echoics, mands, intraverbals, and listener behaviors.

Nonverbal Stimulus Control and the Tact

The distinction between the mand and the tact is based on the distinction between MOs and nonverbal S^Ds as antecedents, and specific and nonspecific reinforcement as consequences. Nonverbal S^Ds, like MOs, can evoke both nonverbal and verbal behaviors. For example, we can respond to rain nonverbally by getting an umbrella, or we can respond to rain verbally by talking about the rain. When the nonverbal properties of the physical environment (e.g., visual or tactile stimulation of rain)

Figure 18.3 Types of mands distinguished by listener behavior.

Mand Type	Speaker's MO	Specific Reinforcement for the Speaker	Reinforcement for Listener Behavior
Request	MO for action on the part of a willing listener	Listener complies	Generalized conditioned reinforcement
Command	MO for action on the part of an unwilling listener	Listener complies	Remove aversive threat
Prayer	MO to generate an emotional disposition	Emits praying behavior	Improves emotional condition
Question	MO for verbal action	Verbal information provided	Generalized conditioned reinforcement
Advice	MO for the listener to enjoy consequences	Listener takes advice	Accesses reinforcement and avoids punishment
Warning	MO to inform the listener of a possible aversive stimulus	Listener following warning	Avoiding aversive stimulus
Offer	MO to get an unwilling listener to participate	Listener participates	Experiences something new
Permission	MO to remove an aversive stimulus	Aversive stimulus removed	Behave without negative ramifications
Call	MO for a listener's attention	Listener emits attending behavior	Reinforcement from additional speaker behavior

evoke a verbal response that is followed by generalized S^r, Skinner (1957) termed this verbal relation a *tact* (Figure 18.1).

Michael (2004) defines nonverbal stimuli as environmental changes (e.g., offset to onset of a stimulus) that affect our receptor systems (e.g., vision, hearing, vestibular). When a particular nonverbal stimulus (e.g., rain) evokes a particular response, and that response is immediately followed by reinforcement, stimulus control develops. Skinner (1957) identified two general types of nonverbal stimulus control that work together as a form of convergent multiple control to evoke verbal behavior: (1) the audience that "controls a large group of responses" (p. 81) and (2) "nothing less than the whole of the physical environment—the world of things and events which a speaker is said to 'talk about'" (p. 81).

Classifying Tact Relations

Classifying tacts can be accomplished by identifying the different types of nonverbal S^Ds that control responses, and by the different ways these verbal responses affect the behavior of the listener. In addition, nonverbal S^Ds commonly interact with other nonverbal S^Ds, verbal S^Ds, and MOs. Several ways to classify various nonverbal S^Ds and tacting will be briefly described.

Different Sensory Receptors

Tacts can be classified by the sensory receptor affected by a nonverbal stimulus. Visual stimuli have functional properties that are different from auditory stimuli, tactile stimuli, olfactory stimuli, and so on. For example, a child may emit the tact "ice cream truck" under the auditory nonverbal stimulus of hearing the truck's music, but not be able to emit the same words under the visual nonverbal stimulus of seeing the truck itself.

Parts of Speech

Tacts can be classified by the parts of speech (e.g., nouns, verbs, adverbs) because a unique type of nonverbal stimulus control is often involved for each part. For example, the nonverbal stimuli that evoke many nouns are typically static objects (e.g., dog, house), while the nonverbal stimuli that evoke verbs often involve movement (e.g., jumping, opening). Many adjectives involve a more complex arrangement of nonverbal stimuli in which the same properties can occur in different objects (e.g., green, large, heavy), and these properties are the source of stimulus control, rather than the object itself. For many prepositions, the objects themselves are irrelevant to the discrimination; rather, their spatial relation to each other is the relevant source of nonverbal control (e.g., next to, on, over). The nonverbal stimulus control involved in other parts of speech (e.g., pronouns, adverbs) can be analyzed in a similar manner.

Multiple Nonverbal Stimuli

Most nonverbal circumstances involve multiple nonverbal stimuli. At a basic level, a single stimulus (e.g., dog) comprises multiple nonverbal stimuli (e.g., a tail, paws, fur). Most encounters with the environment involve multiple nonverbal S^Ds of many types (e.g., objects, actions, relations). For example, the tact "The dog is begging," upon observing a dog, contains multiple nonverbal stimuli, each of which participates in evoking the response. The different parts of speech in the sentence are controlled by a different nonverbal source of stimulus control. The noun "dog" is controlled by the nonverbal object, the verb "begging" is controlled by the dog's actions, and the verb "is" is a relational autoclitic informing the listener of the coordinated relation between the dog (noun) and begging (verb). When a sentence contains other parts of speech (e.g., adjectives,

pronouns) additional nonverbal S^Ds participate in evoking a response. Thus, what may appear to be a single utterance with a single "meaning" is actually multiple responses controlled by multiple variables.

Convergent Multiple Control Involving Nonverbal S^Ds, Verbal S^Ds, and MOs

Nonverbal S^Ds commonly participate in verbal episodes with other types of antecedent variables. For example, nonverbal and verbal S^Ds are involved when a child is asked, "What shape is this paper?" Saying "rectangle" is multiply controlled by the actual (nonverbal) shape of the paper and by the (verbal) spoken word "shape." If the question was "What *color* is this paper? a different response would be evoked. This combination of controlling variables makes the response part tact and part intraverbal, and both sources of control are required to be correct. Nonverbal S^Ds can also share control with MOs. For example, an MO related to a cut finger and the nonverbal S^D of a Band-Aid box evoke selection behavior.

Tact Control

Multiple control can also play a role when the nonverbal antecedent is, by itself, insufficient to evoke the relevant response (Palmer, 2016). For example, if a person cannot correctly remember the name of someone she is talking with, supplemental verbal stimuli (e.g., discussion of a shared work experience) may help to evoke recall. Extending Palmer's (2016) concept of intraverbal control to situations in which the nonverbal stimulus is insufficient to evoke the relevant response can be termed *tact control*, suggesting that the nonverbal stimulus is not the primary source of control, but rather a participant in a multiple configuration of antecedent variables.

Private Nonverbal Stimulus Control

Nonverbal stimuli can arise within the skin of a speaker and evoke verbal behavior in the form of a tact. For example, if one tightens her stomach muscles, this response produces a nonverbal response product that can be tacted through the kinesthetic receptors. That is, one can feel her muscles move and tact this movement, although no one else can. Visual imagining can also provide nonverbal S^Ds that can be tacted (e.g., Horne & Lowe, 1996; Miguel, 2018; Skinner, 1974) and thus provide a sometimes valuable supplemental source of stimulus control for behavior for intraverbal behavior. For example, Kisamore, Carr, and Leblanc (2011) demonstrated how intraverbal behavior could be improved by teaching children to emit visual imagining behavior (e.g., imagining a farm when asked to name some farm animals). Visual imagining can also participate in bidirectional naming relations described in a later section (Horne & Lowe, 1996; Miguel, 2018).

A child first learns to tact her own overt behavior (e.g., "I'm dancing") before learning to tact her own covert behavior (e.g., "I feel tired"). A verbal community establishes self-awareness in several ways (Skinner, 1953, 1974). For example, observable overt collateral behavior can inform the community of a private stimulus (e.g., a child limping), and these circumstances can be used to teach the child to tact the private event for herself. Another way a child learns a tact controlled by private nonverbal stimulation is when the private stimuli are accompanied by observable external stimuli (e.g., blood from a cut). The adults can tact the public stimuli (as well as collateral behavior) that are highly correlated with the private stimuli, and provide and teach an appropriate response form (e.g., "ouch") when the private stimulus is present, thus allowing for echoic-to-tact transfer. Private events can become quite complicated when emotions, MOs, verbal S^Ds, nonverbal S^Ds, and other variables interact with each other and the current context and reinforcement contingencies.

Tact Extension

Once a tact relation has been established, the tact response can occur under novel stimulus conditions through the process of stimulus generalization. Skinner (1957) identifies four different levels of generalization based on the degree to which a novel stimulus shares the relevant or defining features of the original stimulus. The four types of **tact extension** are generic, metaphorical, metonymical, and solecistic. In a generic tact extension, the novel stimulus shares all of the relevant or defining features of the original stimulus. For example, if a child learns to tact "tree" in the presence of a maple tree, when shown an oak tree the child correctly tacts it as "tree." When the child encounters a novel nonverbal stimulus that has some, but not all, of the defining features of tree (e.g., a bush) this antecedent may also evoke the response "tree," and exemplifies a metaphorical tact extension.

Another type of generalization to novel stimuli is a metonymical tact extension, in which a novel stimulus does not share any of the defining features of the original stimulus, but some irrelevant feature acquires stimulus control. For example, a child may have a tendency to call a swing a "tree" if there was a swing on the tree, and it was the swing that acquired stimulus control over the response "tree" due to a history of reinforcement. The fourth type of novel tacting, termed *solecistic extension*, may occur when the property that acquires control has no clear connection to the defining properties. For example, there appears to be no connection between tacting the nonverbal stimulus shoe as a "tree," although these types of solecistic extensions can occur.

Tact Abstraction

Tact abstraction involves learning to tact a property (e.g., color, size, shape) regardless of the object itself. For example, the color red can appear as part of a wide range of nonverbal stimuli (e.g., red cars, red clothing, red fruit). Several of the parts of speech involve abstractions, such as adverbs (e.g., fast, slow) and prepositions (e.g., near, above), where the properties of movement and location, respectively, must acquire control over behavior regardless of the context in which that property appears.

Reinforcement Controlling the Tact

In addition to the different types of antecedent variables that distinguish the mand from the tact, different types of reinforcement define each operant as well (Braam & Sundberg, 1991;

Saunders & Sailor, 1979; Stafford, Sundberg, & Braam, 1988). The mand relation involves specific reinforcement, while the tact relation involves generalized S^r. Skinner (1957) identified five different types of generalized S^r for tacting provided by listeners; three are delivered by a second person serving as a listener: (1) educational reinforcement, (2) escape from or avoidance of aversive stimulation, (3) extending the listener's contact with the environment; and two are self-delivered by the speaker acting as her own listener: (4) automatic reinforcement, and (5) a history of contiguous or correlated usage.

Educational Reinforcement

A child's ability to correctly identify objects and events in her physical environment is an important aspect of language development, and parents and other caregivers take special effort to establish this behavior. Skinner (1957) suggests that the type of generalized S^r involved can be identified as educational reinforcement, and he defined it as "reinforcement supplied primarily because it establishes and maintains a particular form of behavior in the speaker" (p. 84). For example, teaching a child to tact body parts involves antecedents, behavior, and consequences (a discrete trial), with differential reinforcement explicitly provided for purposes of instruction. It could be considered contrived reinforcement contingencies; nonetheless, these contingencies are valuable for establishing a child's early tacting vocabulary or for repairing a child's impaired tact repertoire.

Escape from or Avoidance of Aversive Stimulation

The removal of something that is aversive to a person can function as a type of negative reinforcement, thus strengthening behavior. If a threatening tone of voice accompanies a nonverbal stimulus (e.g., a harsh "What is it?" in a teaching trial), it might be that the removal of the aversive stimulus is a more powerful consequence than social praise (e.g., Carbone, Morgenstern, Zecchin-Tirri, & Kolberg, 2008).

Extending the Listener's Contact with the Environment

The main reinforcement for tacting is the action that listeners take as a function of the speaker's tact. Michael (1991) explains this effect in the following manner: "As a result of the speaker's tact, the listener is able to do something that he could not have done without the speaker's tact, and for this reason provides generalized S^r" (p. 35). For example, if a driver (as a listener) cannot see an oncoming car, a passenger's (as a speaker) tact "There's a car coming" extends the driver's contact with the physical environment, and allows him to behave more effectively. This reinforcement is not contrived and produces effective listener behavior, and the listener provides reinforcement for that reason (e.g., "Thanks").

Automatic Reinforcement

Environmental contingencies can affect behavior without the immediate involvement of other people. For example, the reinforcement obtained from swimming may emanate from the behavior itself—that is, it feels good. Skinner (1957) used the term "automatic" to identify circumstances in which a behavior is evoked, shaped, maintained, or weakened by environmental variables occurring without direct manipulation by other people. Vaughan & Michael (1982) note that Skinner's usage of *automatic* was simply to counteract "any tendency to restrict the concept of reinforcement to those occasions upon which it has been deliberately arranged by another person or group" (p. 218). Skinner (1957) also discussed automatic punishment (p. 375), automatic extinction (p. 164), automatic consequences (p. 442), automatic shaping (p. 58), automatic MO control (p. 220), and automatic stimulus control (p. 416). In short, all the basic principles of behavior can operate on a person automatically, and all **automatic contingencies** have the same defining properties as non-automatic contingences. Thus, antecedents and consequences that are not deliberately arranged can affect behavior, often in a manner more efficient than directly manipulated contingencies (Palmer, 1996; Skinner, 1968).

Among the various types of automatic contingencies, automatic reinforcement has received the most attention from behavioral researchers. Automatic reinforcement can occur in two ways: (1) where the reinforcement emanates from the response product of the behavior (e.g., infant babbling, singing songs, mannerisms, emitting a clever phrase) and (2) where the reinforcement is provided by the behavior's reinforcing effects emanating from the physical environment (e.g., turning on a light, finding a missing phone). Both types of automatic reinforcement can produce an increase in the behavior they follow without involvement from another person.

The automatic reinforcement concept has many applications to language instruction and problem behaviors, along with a growing body of empirical research supporting its use (e.g., Chapter 27; Shillingsburg, Hollander, Yosick, Bowen, & Muskat, 2015; Stock, Schulze, & Mirenda, 2008; Sundberg, Michael, Partington, & Sundberg, 1996; van Harran, 2015; Vollmer, 1994). In addition, Donahoe and Palmer (1994) and Palmer (1996, 1998) describe how automatic reinforcement participates in the development of more complex aspects of verbal behavior. For example, these authors suggest that a child's grammar produces automatic reinforcement when it sounds like grammar emitted by others in their verbal community, but is automatically punished when it sounds odd or unusual. Palmer (1996) described this effect as achieving *parity* with others. Several studies have demonstrated how automatic reinforcement participates in establishing and refining grammatical and syntactical skills (e.g., Østvik, Eikeseth, & Klintwall, 2012; Wright, 2006).

A History of Contiguous or Correlated Usage

Each speaker has a unique and private history of reinforcement relevant to her own verbal behavior. This history is brought to bear on current environmental contingencies, and the two sets of variables interact. For example, if a friend is talking about a recent bike trip to Nova Scotia, and you as a listener have also biked around Nova Scotia, a number of covert verbal behaviors and nonverbal imagery may come to strength. The response products of these covert verbal behaviors prepare you for your upcoming speaker role. "Nova Scotia" as a verbal S^D may covertly evoke "Halifax" or "Immigration Station" as a self-intraverbal. A covert visual image of flowers along the road may also function as a nonverbal S^D that evokes "lupines" as a

self-tact. These effects occur because of a history of reinforcement in which these different stimuli occurred together either contiguously or simply correlated (Palmer, 2016). Skinner terms this effect *contiguous usage*, noting, "In general there is an advantage if responses appropriate to a current situation are strong" (p. 86). These responses are self-strengthened by the automatic reinforcement they produce. In addition, their occurrences evoke speaker behavior that increases the probability that the listener will provide generalized S^r (e.g., "I enjoyed the lupines too").

Generative Learning

Typically developing children demonstrate an explosion of language skills between the ages of 2 and 3 (Brazelton & Sparrow, 2006; Greer & Ross, 2008; Hart & Risley, 1995). During that period, a child begins to emit and comprehend new words daily, and vocabulary size can grow from 100 to 1000 words. A child may combine and expand on these new words in novel ways and in novel contexts, often without direct training or a history of reinforcement (e.g., a toddler who shocks an audience with a swearword). Young children seem to learn new words on their own. However, some children, especially those with autism, struggle with or fail to make this leap in language acquisition.

Some emergent verbal behavior can be explained by stimulus and response generalization, but others involve a process of generalization that goes under the rubric of generative learning. **Generative learning** involves a behavioral effect where previously acquired skills enable or accelerate the acquisition of other skills, without dependence on direct teaching or a history of reinforcement (Alessi, 1987; Horne & Lowe, 1996; Staats, 1996; Stewart, McElwee, & Ming, 2013). There are several productive lines of research on generative learning, each of which has contributed to our understanding of this important behavioral effect (e.g., Becker, 1986; Engelmann & Carnine, 1982; Goldstein, 1983; Greer & Ross, 2008; Hayes et al., 2001; Hixson, 2004; Horne & Lowe, 1996; Johnson & Layng, 1994; Koegel & Koegel, 1988; Lowenkron, 1998; Malott, 2003; Rosales-Ruiz, & Baer, 1997; Sidman, 1994; Staats, 1996). The concept of behavioral cusps (Rosales-Ruiz & Baer, 1997) can help organize the topic of generative learning, especially as it applies to early language acquisition (Greer & Ross, 2008). In addition, the work of Staats (1996) on cumulative-hierarchical learning can help to provide a conceptual foundation for generative learning (Hixson et al., 2010). The following section will describe several ways that generative learning can produce emergent tact relations.

Emergent Tact Relations

Stimulus Equivalence

Sidman (1971) and Sidman & Cresson (1973) showed that combining matching-to-sample (MTS), echoic, and listener skills generated emergent MTS, tact, and textual relations. Sidman termed this effect *stimulus equivalence* (Chapter 19). These researchers showed that equivalence can be established by using conditional discrimination procedures to directly teach a single AB relation between a word (stimulus A) and an object (stimulus B), then teach a BC relation between the same object (stimulus B) and a different stimulus (stimulus C), and then test for the emergence of the untrained relations (i.e., BA/CB symmetry tests and AC/CA transitivity tests). When emergence occurs with both symmetry and transitivity, equivalence has occurred (Sidman & Tailby, 1982). Pilgrim (Chapter 19) describes the emergent tact and textual responses in Sidman's early work as follows: "The exciting result was that these boys not only named the pictures correctly, but also the written words; that is they read the words orally where they had not been able to do so prior to the teaching phases" (p. 456). Since Sidman's initial work, equivalence procedures have proved an effective method for producing a host of generative learning effects (Chapter 19).

Recombinative Generalization

Goldstein (1983) defined recombinative generalization as "differential responding to novel combinations of stimulus components that have been included previously in other stimulus contexts" (p. 280). For example, if a child is taught to tact "green circle" and "red square" and then without direct training the child is able to correctly tact "green square" and "red circle," then recombinative generalization has occurred. Matrix training is an example of a commonly used procedure that can produce recombinative generalization, and studies have demonstrated its effectiveness in generating emergent tact relations (e.g., Axe & Sainato, 2010; Frampton, Wymer, Hansen, & Shillingsburg 2016; Kohler & Malott, 2014; Pauwels, Ahearn, & Cohen, 2015).

Common Bidirectional Naming (C-BiN)

Horne & Lowe (1996) suggested that one of the most far-reaching achievements in early language acquisition occurs when the echoic, tact, listener, and self-listener skills combine to establish a new higher order verbal cusp they term common **bidirectional naming**. Once a child can easily echo new words, and has acquired the basic prerequisite repertoires for C-BiN, a new word acquired as listener can immediately generate speaker behavior (a tact) without further training; or if the word is first acquired as a tact, it can immediately generate a listener relation without further training (consistent with symmetry and mutual entailment). A reinforcement history of naming experiences (multiple exemplar instruction) and self-echoic mediation establishes bidirectional relations between words and objects or events, and fuses the speaker and listener repertoires (Greer & Ross, 2008; Horne & Lowe, 1996; Miguel, 2016, 2018). The naming cusp is far-reaching, so much so that Greer and Longano (2010) assert the following: "Naming appears to be the source of the explosion in language development" (p. 73). In addition, C-BiN teaching procedures have shown effectiveness in producing generative learning for children with disabilities who have failed to acquire this important form of learning (e.g., Fiorile & Greer, 2007; Lee, Miguel, Darcey, & Jennings, 2015).

Joint Control

Lowenkron (1984, 1988, 1989) demonstrated that emergent speaker and listener behavior could be generated by a type of multiple control he termed *joint control*. Joint control also involves the combination of verbal skills (e.g., echoic and tact repertoires) and occurs when two separately established

antecedents that evoke the same response topography arise simultaneously. For example, when searching for a specific reference from a list of references, a self-echoic (e.g., "Guttman and Kalish") is rehearsed (overtly or covertly) until a textual stimulus evokes the same response form (e.g., reading "Guttman and Kalish"). The physical similarity of the two response forms generates a nonverbal S^D regarding that similarity and evokes an emergent autoclitic tact (e.g., "that's it"). The response product of the autoclitic tact, along with the textual stimulus, sets up the conditional discrimination that evokes the emergent listener behavior (e.g., copying and pasting the reference). Once joint control is acquired as a generalized repertoire (a higher-order cusp), its generative effects can allow for, or accelerate, a host of complex speaker and listener behaviors (e.g., Causin, Albert, Carbone, & Sweeney-Kerwin, 2011; Lowenkron, 1998, 2006; C. T. Sundberg et al., 2018; Tu, 2006).

Relational Frame Theory (RFT)

Hayes et al. (2001) extended Sidman's equivalence framework to nonequivalent relations such as comparison, opposition, and difference (Chapter 20). Generative learning opportunities that can produce emergent tacts are abundant when equivalent and nonequivalent relations interact in novel contexts. Once acquired as a generalized operant, relational responding functions as a higher-order cusp capable of generating a number of far-reaching derived effects (e.g., Dougher, Augustson, Markham, Greenway, & Wulfert, 1994; Hayes et al., 2001; Stewart et al., 2013). In RFT, framing is established through a history of multiple exemplar training and combined in various ways dependent on the current context. This history and the current contingencies provide the foundation for the establishment of derived relational responding.

A defining feature of derived relational responding is the transformation of stimulus functions, which includes all types of transfer (e.g., mutual entailment, combinatory entailment, transformation of function) (Dymond & Rehfeldt, 2000; Hayes et al., 2001). Unique to RFT is the treatment of the transformation of psychological function (e.g., Dougher et al., 1994; Dymond & Barnes, 1994). In this type of transformation, "[i]f one stimulus in a mutual or combinatorially entailed relation is given a direct psychological meaning, then the remaining stimuli may acquire this psychological function. For example, if 'lemons' is in an equivalence class with actual lemons in a context that selects taste as the relevant function, talking of lemons can be associated with salivation or puckering" (Hayes, Gifford, & Ruckstahl, 1998, p. 289). For individuals with language delays, the transformation of function and related relational framing activities can provide teaching tools for establishing generative networks of stimulus relations that can be emitted, expanded, and merged under a variety of contexts (e.g., Dixon, 2016). To learn more about derived relational responding, see Chapter 20.

Verbal Behavior Controlled by Verbal S^Ds

Verbal S^Ds constitute the third type of antecedent control for language, joining MOs and nonverbal S^Ds. as sources of control for both speaker and listener behavior. We commonly respond to the words of others, and to our own words as a speaker or a listener. We have conversations, surf the Internet, read, write, and so on. Skinner (1957) defines a verbal stimulus as "the product of earlier verbal behavior" (p. 65). That is, verbal responses produce a response product. For example, vocal speech produces auditory stimuli, sign language produces visual stimuli, and Braille dots produce tactile stimuli. These response products can in turn have a discriminative or motivative function evoking the behavior of listeners, including the speaker as her own listener.

Verbal S^Ds have the same causal status as nonverbal S^Ds in that both types of S^Ds acquire discriminative control over behavior through a history of differential reinforcement. Verbal S^Ds have unique effects and characteristics not found with nonverbal S^Ds (Sundberg, 2016a). For example, verbal S^Ds can be portable, private, and free from environmental support. We can talk about being in Italy without being in Italy, recite the numbers to open a combination lock, solve problems, or think through an important decision, all in the absence of the relevant physical stimuli. The verbal response products of this talk may function as automatic S^r, as well as S^Ds or MOs evoking other behaviors. Nonverbal S^Ds, by contrast, are restricted to the immediate physical environment (with the exception of imagining), and are far less portable or available to a speaker across environments.

Six types of elementary verbal operants are controlled by verbal S^Ds: echoic, motor imitation (relating to sign language), copying text, textual, taking dictation, and intraverbal (Figure 18.1). All of these verbal operants, except the intraverbal, can be classified as duplic or codic.

The Duplic Relations: Echoic, Motor Imitation, and Copying Text

Duplics are the least complex of the verbal operants but play a significant role in linguistic and academic development. This category of verbal operants involves verbally copying verbal stimuli. Verbal stimuli can occur in many forms (e.g., spoken words, written words, gestures, sign language, fingerspelling, Braille dots). These can be organized into three distinguishable types: echoic (auditory match), motor imitation as it relates to sign language (visual match), and copying text (e.g., copying configurations of written letters, fingerspelling, or Braille dots).

Echoic. A child's ability to echo the phonemes and words of others is essential for learning to identify objects and actions. In the presence of a duck a parent might say, "That's a duck, can you say duck?" If the child can respond "duck," then the parent says "Right!" Eventually, the child learns to name a duck without the echoic prompt. Echoic behavior also plays a critical role in more complex forms of verbal behavior, such as incidental verbal learning, derived relational responding, joint control, bidirectional naming, and problem solving (e.g., Hayes et al., 2001; Horne & Lowe, 1996; Lowenkron, 2006; Palmer, 2012; Schlinger, 2008a, 2008b).

Motor Imitation. Some types of motor imitation constitute nonverbal behavior (e.g., following others to get in a line), while others can have the same functional properties as echoic

relations. Motor imitation is a valuable tool for teaching sign language to persons who are deaf, or hearing but unable to produce speech. For example, a child may learn to imitate the sign for popcorn while popping corn, then later emit the sign appropriately without an imitative prompt.

Copying Text. Textual verbal stimuli can be written, fingerspelled, or punched in Braille dots. Learning to copy these stimuli can facilitate the development of codic verbal behavior (e.g., learning to read, write, and spell). For example, a child often first learns to make letters by tracing and copying them, which can facilitate the process of independently writing, spelling, and reading.

The Codic Relations: Textual and Taking Dictation

Codic relations are more complicated than duplic relations because of the lack of formal similarity between the verbal S^D and the verbal response. Michael (1982) notes that the term codic "is meant to suggest the kind of relation seen in a formal code, where one stimulus is said to stand for another stimulus that it does not resemble" (p. 2). In codic relations, additional speaker behaviors are required to learn to code and convert a textual stimulus into a vocal stimulus, and vice versa.

Textual. Textual behavior is reading without an implication that the reader understands what is being read. Understanding what is read is typically identified as reading comprehension and involves a number of functionally separate verbal and nonverbal operants (e.g., intraverbal behavior, manding, tacting, listener discriminations). For example, saying "Chicago" upon seeing the written word "Chicago" is usually textual behavior. But understanding that Chicago is a city on Lake Michigan is not textual behavior (it is more likely intraverbal behavior). Textual behavior can occur with sign language as well. The Stokoe Notation System was designed as a form of written sign language (although not widely used). It has 55 written cheremes that are analogous to the 42 vocal phonemes of English (Stokoe et al., 1965). An arrangement of written cheremes can be read with signs in a manner similar to speech because they have point-to-point correspondence to a specific sign.

Taking Dictation. Taking dictation consists of writing and spelling words that are spoken. The multiple repertoires involved in learning this code include not only the manual production of letters (written, typed, fingerspelled, or punched) but also the spelling of words. As with textual, the code aspect of this repertoire usually requires additional instruction. Taking dictation can occur with sign language as well. This relation involves seeing a sign and writing the corresponding cheremes.

The Intraverbal

The intraverbal relation is different from the other types of verbal behavior evoked by verbal S^Ds in that *no* point-to-point correspondence exists between the verbal stimulus and the verbal response (Figure 18.1). Young children typically emit intraverbal responses in the form of singing songs, telling stories, describing activities, and so on. At a more advanced level, intraverbal behavior is a key component of many important aspects of human behavior (e.g., academics, social interaction, entertainment). As with the other verbal operants, the form of an intraverbal response can involve speech, signs, written words, and so on. And as with the mand and tact, to understand the intraverbal, one must understand its controlling variables. At least four different types of verbal discriminations can be involved in intraverbal relations (Figure 18.4): (1) simple verbal, (2) compound verbal, (3) verbal conditional, and (4) verbal function-altering.

Classifying Verbal Discriminations

Intraverbal relations can be classified by identifying the type of verbal stimulus control that evokes the intraverbal response. In general, each of the verbal discriminations presented below involve increasingly more complex types of verbal stimulus control.

Simple Verbal Discrimination

The first type of intraverbal behavior acquired by typically developing children usually involves **simple verbal discriminations**, where a single-component word or phrase evokes a nonmatching verbal response. For example, upon hearing "Ready, set . . . ," a child says "go," or hearing "Buzz . . . " a child says "lightyear." These early intraverbal responses may be initially multiply controlled by MOs and other supplementary variables (e.g., echoics, tacts), but soon intraverbal stimulus control is established.

Compound Verbal Discrimination

A **compound verbal discrimination** involves convergent multiple control where two or more verbal S^Ds collectively evoke a response. However, the response evoked by the compound stimulus is different from the response evoked by each verbal S^D when presented in isolation (Eikeseth & Smith, 2013). For example, hearing "yellow" might intraverbally evoke any number of responses (e.g., "color," "school bus"), and "fruit" might also evoke any number of responses (e.g., "apple," "orange"), but when combined as "yellow fruit" they evoke a more specific response (e.g., "banana," "lemon"). In a compound verbal discrimination, the individual words do not change the function of each other; they are parts of a larger stimulus configuration, similar to the way individual nonverbal stimuli (e.g., tail, paws) make up objects (e.g., a dog). In the next type of verbal stimulus control presented, the individual words in the antecedent do affect each other.

Verbal Conditional Discrimination (VC^D)

Verbal stimulus control becomes more complicated when verbal stimuli interact with each other in the same antecedent configuration. For example, a conditional discrimination can arise between verbal stimuli in an utterance and more behavior is required to emit intraverbal responses (i.e., questions get harder). A **verbal conditional discrimination** occurs when one verbal stimulus alters the evocative effects of another verbal stimulus

Figure 18.4 Four types of verbal discriminations.

Type of Discrimination	Definition	Example
Simple	A single-component verbal stimulus that evokes a response.	*Speaker*: Saying "meow" after hearing "A kitty says . . ." *Listener*: When asked to "jump" a child emits jumping behavior.
Compound	A verbal stimulus that involves two or more S^Ds that each independently evoke behaviors, hut when they both occur in the same antecedent configuration, a different S^D is generated.	*Speaker:* Saying "blue" after hearing "Red, white, and . . ." *Listener:* When asked to "clap fast," and "clap slow," "walk fast," and "walk slow" the corresponding nonverbal behavior is emitted.
Verbal Conditional	A verbal stimulus that alters the evocative effects of another verbal stimulus in the same antecedent configuration.	*Speaker:* Saying "spoon" and "soap," respectively, when asked, "What do you eat with?" and "What do you wash with?" *Listener:* Pointing to spoon and soap when asked the same questions presented above.
Verbal Function-altering	A verbal stimulus that alters the function of other stimuli or motivating operations (Schlinger & Blakely, 1994).	*Speaker:* Singing at the right time after hearing "When I call your name, sing your part." *Listener:* After hearing "When the doorbell rings, get your father," the correct behavior is emitted at the right time.

within the same antecedent configuration, and that stimulus evokes the response (Axe, 2008; Catania, 2013; Devine, Carp, Hiett, & Petursdottir, 2016; Eikeseth & Smith, 2013; Kisamore, Karsten, & Mann, 2016; Michael et al., 2011; Sundberg, 2016a; Sundberg & C. A. Sundberg, 2011). For example, in the verbal antecedent "Who is not going to dinner?" the reinforcement history related to the conditional word "not" alters the evocative effects of the phrase "going to dinner," changing it to a different verbal S^D that evokes a corresponding intraverbal response. A VC^D effect can be demonstrated by showing a change in the evocative effect when the verbal stimulus is altered to "Who is going to dinner?"

Verbal Function-altering Effect

Verbal stimuli can alter the functional effects of immediate or future S^Ds and MOs and, accordingly, change a listener's behavior. The immediate effects involve straightforward operant and respondent conditioning, but the changes in future behavior are more complex. For example, being told "The bridge is out, turn left at the 7-Eleven and there will be another one in 5 miles" can alter the functional effects of stimuli encountered in the future and evoke verbal and nonverbal behavior at that time (e.g., tacting the 7-Eleven, turning left). Skinner (1957) described this type of effect as *conditioning the behavior of the listener* (p. 357) through instruction. Schlinger and Blakely (1994) and Schlinger (2008b) suggested the term **verbal function-altering** be used to describe the effect that occurs when verbal stimuli immediately condition the behavior of the listener and produce relatively permanent changes in the behavioral function of other stimuli and MOs occurring immediately or later in time The future behavior of a listener can involve any speaker, listener, or respondent relation. Schlinger and Blakely (1987, 1994) suggested that the use of Skinner's (1969) term *rule-governed behavior* be reserved for these types of verbal function-altering effects.

The conditioning of a speaker's future intraverbal behavior would first involve the initial listener conditioning and then an encounter with the newly established verbal stimulus. For example, if a peer says to a teenage friend, "When your mother asks where did you go, tell her the library." Upon encountering the mother's question later, it evokes "the library" as instructed. Under other circumstances, hearing "Where were you?" would have different evocative effects (e.g., "track practice"). However, it is important to note that "this does all not happen in the naïve speaker or listener; it is the end result of a long process of verbal conditioning" (Skinner, 1957, p. 360).

Convergent Multiple Control Involving Verbal S^Ds, Nonverbal S^Ds, and MOs

Verbal S^Ds not only combine with each other as a type of multiple control but also commonly participate with nonverbal S^Ds, MOs, and respondent relations in the control of behavior. As with other examples of convergent multiple control, the effect of combining multiple variables can be additive or decremental. On the one hand, verbal S^Ds can provide a welcome addition to nonverbal stimuli, such as the information provided by a tour guide while viewing an historical site. On the other hand, verbal S^Ds can weaken, block, or distort control by other nonverbal stimuli, verbal stimuli, and MOs. For example, when someone talks during a movie scene the nonverbal action or dialog might be missed.

Intraverbal Control

A distinction can be made between verbal S^Ds that depend on multiple control with nonverbal S^Ds and MOs, and those that do not. Those that do not require multiple control, and have the relevant reinforcement history, can be classified as an intraverbal operant (e.g., upon hearing "What's 6 × 8" a child immediately says "48"). However, some verbal stimuli only supplement other more critical antecedents, but nonetheless play a causal role in evoking behavior. Palmer (2016) recommends that "In cases in which the verbal antecedent is, by itself, insufficient to evoke the relevant response, we should speak of intraverbal control, usually as one of a number of concurrent controlling variables" (p. 99). For example, a common practice in tact training for children with language delays is to hold up an object and say, "What is it?" The verbal stimulus "What is it?" by itself is insufficient to evoke the correct response, but, along with the presented object, it can be an important supplemental S^D that helps to evoke a response from a child learning tacts.

Private Verbal Stimulus Control

Verbal stimuli, like MOs, are free from the support of the physical environment; thus they can be portable and private. We can and do talk to ourselves, often to our benefit (e.g., self-editing, problem solving, thinking) (see Box 18.1). Our own covert verbal behavior provides an abundant supply of verbal stimuli (sometimes too much). These verbal stimuli are no different in function than overt verbal stimuli, except only one person can experience the S^D or MO effect. Covert verbal stimuli can combine with other variables, including overt variables. For example, while traveling through an airport and looking for the right terminal and gate, passengers may engage in a series of overt or covert verbal behavior that assists them in navigating various transitions. This verbal behavior can involve self-echoics (e.g., "Gate B31"), self-intraverbals (e.g., "B31 is in a different terminal"), self-textual (e.g., reading the gate signs), and joint control, all of which can participate as causal variables that ultimately evoke going to the right gate. Covert verbal S^Ds have received little experimental attention due to the privacy issue; nonetheless, they can play an important role in the interpretation of complex behavior (Moore 2008; Palmer, 2011; Schlinger, 2008a; Skinner, 1974; C. T. Sundberg et al., 2018).

Reinforcement Controlling the Duplic, Codic, and Intraverbal Relations

Generalized S^r provided by listeners (e.g., praise, approval) establishes verbal stimulus control over verbal behavior, in the same way it does for nonverbal stimulus control. Four of the five types of reinforcement identified for the tact relation apply to the duplic, codic, and intraverbal relations as well: (1) educational reinforcement, (2) termination of aversive stimuli, (3) automatic reinforcement, and (4) a history of contiguous or correlated usage. The form of reinforcement that does not apply was identified as reinforcement from extending the listener's contact with the physical environment, and that form is unique to the nonverbal stimulus control. However, Skinner identifies an additional type of generalized S^r unique to verbal stimulus control; this type can be termed *facilitative reinforcement.*

Facilitative Reinforcement. Skinner (1957) states that verbal behavior "may be reinforced because it helps in the acquisition of other types of verbal operants" (p. 67). Facilitative reinforcement functions as a type of automatic reinforcement, like that observed in emitting a chain of verbal behaviors in problem solving. The successful acquisition of the next step in the chain is facilitated by an earlier step. Such facilitative reinforcement plays a causal role in more complex behavioral relations such as joint control and BiN. For example, repeating instructions (e.g., turn left at the 7-Eleven) while driving can facilitate the emergence of joint control when the 7-Eleven is encountered (Lowenkron, 1998).

Emergent Intraverbal Relations

Research has demonstrated that intraverbal relations can emerge from previously acquired tact, intraverbal, and listener repertoires, and even from direct observation (e.g., Allan, Vladescu, Kisamore, Reeve, & Sidener, 2014; Braam & Poling, 1983; Devine et al., 2016; Grannan & Rehfeldt, 2012; Pérez-González & García-Asenjo, 2016; Pérez-González, García-Asenjo, Williams, & Carnerero, 2007; Petursdottir, Carr, Lechago, & Almason, 2008; Smith et al., 2016). There are also ways that new intraverbal behavior can emerge from the combinations of existing verbal repertoires (DeSouza, Fisher, & Rodriguez, 2019; Horne & Lowe, 1996).

Intraverbal Bidirectional Naming (I-BiN)

Horne and Lowe (1996) suggested that emergent intraverbal relations could also be produced through intraverbal bidirectional naming (I-BiN) procedures (Miguel, 2016). In I-BiN a bidirectional relation is established between at least two verbal stimuli (e.g., "cat" and "animal"). I-BiN occurs when AB training on a unidirectional intraverbal relation automatically produces a reverse BA intraverbal relation, and vice versa. For example, after learning the unidirectional intraverbal relation between "cat" as the verbal S^D and "animal" as the verbal response, without further training a child can emit "cat" as the response when "animal" is the verbal S^D. The components of I-BiN consist of a combination of echoic, self-echoic, listener, self-listener, and tact repertoires working together. Once established, I-BiN, like C-BiN, can function as a higher-order generalized verbal operant that can produce powerful generative effects (e.g., Horne & Lowe, 1996; Greer & Ross, 2008; Jennings & Miguel, 2017; Miguel, 2016, 2018; Pérez-González et al., 2018).

Simple I-BiNs can be established by teaching a child a relation between two verbal stimuli (e.g., "shoes and socks"), and then teaching the child to emit overt or covert self-echoic repetitions of the trained intraverbal relation (e.g., "shoes and socks, shoes and socks"). When repeated, the basic components of the reverse intraverbal are contained contiguously in the phrase (i.e., the word "shoes" now follows the word

BOX 18.1

I Shouldn't Have Opened My Big Mouth: Skinner's Analysis of Self-Editing

Some people may say things that are offensive, socially inappropriate, or untruthful. Others may make frequent verbal mistakes, tangle their words, or digress repeatedly. Skinner devoted three chapters to self-editing (Chapters 15 to 17) in his book *Verbal Behavior* (1957). He emphasized that a speaker is also a listener, including a listener of her own verbal behavior and may, to her benefit, self-edit that verbal behavior before or soon after it is emitted. Self-editing is extra work for a speaker and occurs due to a history of reinforcement or punishment from listeners. However, Skinner notes that in many cases punishment may play a larger role in self-editing than reinforcement.

Some types of language and social problems can be related to self-editing deficits. Skinner (1957) suggests two behavioral distinctions be made when considering self-editing problems. The first is between a speaker who cares about what she says and a speaker who does not care about what she says. Caring involves a motivating operation (MO) that is related to a history of reinforcement and punishment from listeners. The same speaker may care that her verbal behavior obtains a positive listener response from one audience, but not from another audience. Caring can also involve MOs related to negative responses from listeners. A speaker may care that her words hurt others.

A second distinction can be made between a speaker who is aware of what she says and its effect on listeners and a speaker who is unaware of what she says or its effects. This distinction is based on the degree to which a speaker can tact aspects of her own verbal behavior (e.g., that certain words might be offensive) and aspects of her listener's behavior (e.g., noticing a nonattentive listener), and behave accordingly. Three examples of self-editing problems based on these distinctions are presented, along with some comments regarding intervention.

Offensive Verbal Behavior

Some individuals are aware of the offensive, hurtful, or socially negative things they say to people, but they may not care. They may demonstrate weak MOs for positive reactions from listeners, strong MOs for negative reactions from listeners, or strong MOs for social reinforcement from peers for their offensive behavior. People who say negative things to other people may not seek treatment because they do not feel anything is wrong. It may be hard to change this behavior because of the difficulty in controlling the relevant contingencies, especially the MOs.

Weak Verbal Repertoires

Some individuals are aware of their difficulties in expressing themselves. They might be insecure about what they say, tangle their words, or struggle with public speaking. Individuals experiencing these problems typically care about what they say, but they may have weak intraverbals, fail to tact listener behavior, or have interfering MOs and emotional responses. These individuals are more likely to seek treatment (e.g., Toastmasters, public speaking courses). Skinner (1957, pp. 405–417) describes several techniques for teaching a willing participant to edit her own verbal behavior (e.g., rehearsal with familiar audience, self-prompts, practice self-listening, practice tacting listener behavior, change the audience, change the motivation).

High Rate of Verbal Behavior

Some people may be unaware of the effects of their words on listeners, but they do care (a strong MO) that people respond positively. These individuals may engage in a high rate of talking, dominate a conversation, or provide excessive detail regarding events or their topic of interest. Typically, punishment reduces this behavior, but there may not be enough punishment, or other listeners intermittently reinforce the behavior. These speakers may be automatically reinforced by their own verbal behavior, have weak listener repertoires, or have weak MOs for the listener's point of view. Individuals experiencing these types of editing problems may not seek treatment because they are unaware that a problem exists, although intervention could be successful.

Summary

Skinner's three chapters on self-editing provide a behavioral analysis of many types of self-editing issues and problems. We may open our big mouths, then wish we had not, because we failed to edit our verbal behavior before it was emitted. Self-editing requires extra work for a speaker and may not occur for that reason. Skinner (1957) offers many practical suggestions for clinicians and others interested in understanding or improving self-editing repertoires.

"socks"), and this response is followed by direct or automatic reinforcement (Vaughan & Michael, 1982). When this reverse intraverbal emerges without training, this I-BiN effect is consistent with symmetry and mutual entailment (e.g., Horne & Lowe, 1996; Miguel & Petursdottir, 2009; Pérez-González et al., 2007; Petursdottir & Haflidadóttir, 2009). Once simple bidirectional relations are established between words, new words can be added to the class (e.g., "feet" "shirt") and ever more forms of emergent intraverbal behavior can occur (e.g., saying "feet" upon hearing "shoes go on your . . . ").

When a stimulus change affects one member of an I-BiN class, its effects can transfer to all members of the class.

For example, if a child has acquired the C-BiNs "dangerous" and "spider," and then learns the I-BiN "spiders are dangerous," this new verbal stimulus can produce a generative verbal function-altering effect (Schlinger & Blakely, 1994) for the whole stimulus class of spiders. For example, later when the child sees a spider, if she tacts the spider the response product of the tact (i.e., hearing the word "spider") evokes the intraverbal response "dangerous," bringing with it a history of listener behavior. Furthermore, the nonverbal stimulus of the spider is present when reinforcement is delivered, and as a result the tact of the spider as "dangerous" may also emerge. The new tact and intraverbal relations involving the word "dangerous" are likely members of several different equivalent and non-equivalent classes, and their effects can transfer throughout those classes (Chapter 20). For example, the previously neutral spider may now function as a conditioned stimulus and elicit respondent behaviors or as a CMO-R that evokes avoidance behaviors or as a nonverbal S^D that evokes the emergent tact "dangerous."

The verbal function-altering effect can also transfer to any stimulus that is in the same equivalence class as spiders (e.g., mosquitoes, ants, crickets) and similar respondent, avoidant, and tacting behavior can emerge. What makes this transformation of function important to generative language is that it demonstrates how an emergent tact relation can produce an emergent intraverbal relation, further demonstrating the far-reaching effects of combining verbal cusps (Greer & Ross, 2008; Hayes et al., 2001; Horne & Lowe, 1996; Rosales-Ruiz & Baer, 1997).

There is a growing body of research on more complex I-BiNs and their generative effects (e.g., Carp & Petursdottir, 2015; Greer & Ross, 2008; Jennings & Miguel, 2017; Ma, Miguel, & Jennings, 2016; Pérez-González et al., 2018; Santos, Ma, & Miguel, 2015). For example, Jennings and Miguel (2017) examined the effects of intraverbal and tact training on the emergence of stimulus equivalence. These researchers first taught 17 adult participants to tact birds (A), trees (B), and reptiles (C). Then the experimenters taught them unidirectional intraverbal relations between specific sets of stimuli (e.g., "The tree for Cardinal [A1] is Buckeye [B1] and the reptile for Buckeye [B1] is Black Racer [C1]"). Participants were then administered a visual-visual MTS test and an intraverbal test to assess performance for equivalence class formation. In addition, participants experienced four novel sets of stimuli to assess for generalization. The results for 4 of the 17 participants are presented in Figure 18.5. The closed circles, squares, and triangles represent three types of matching-to-sample tasks that constitute equivalence. Baseline data on equivalence show that these participants responded at chance level. However, following tact and intraverbal training, all 4 participants demonstrated nearly 100% correct performance on all equivalence measures. In addition, all the participants demonstrated emergent intraverbal behavior that participated in establishing the equivalence relations. In total, 13 of the 17 participants demonstrated the emergence of stimulus equivalence. These authors concluded that the participant's equivalence performance was established by the participant's own C-BiN and I-BiN verbal behavior.

LISTENER BEHAVIOR

Skinner's *Verbal Behavior* (1957) was primarily about the behavior of the speaker, but Skinner argued that a complete account of language must include both speaker and listener behavior. In contrast, linguists tended to ignore the speaker and were mainly concerned with the listener (Skinner, 1978). Gradually however, Skinner's book began to affect linguistic theory (Andresen, 1991). In a letter Skinner sent to me in 1989 (see Box 18.2) he muses, "It is quite amazing how linguists are coming around to the position of my book. They had to get around to the behavior of the speaker sooner or later, having spent centuries on how verbal behavior is understood by the listener." Despite Skinner's focus on the speaker, Schlinger (2008b) noted the following: "Skinner did not neglect the listener. In fact, he made frequent mention of the listener throughout the book—the word *listener* occurs 793 times compared to 893 instances of the word *speaker*" (p. 312). In addition two chapters of *Verbal Behavior* are primarily devoted to analyses of listener behavior (Chapters 6 and 7).

Different Roles of a Listener

A **listener** is an active participant in verbal exchanges and serves many roles in this capacity. Skinner (1957) makes a distinction between the nonverbal and verbal duties of a listener. The nonverbal duties include serving as an audience (an S^D or MO) and providing reinforcement for speakers. Reinforcement for a speaker typically involves some kind of listener action directly controlled by the speaker's words. Listener action can be nonverbal (e.g., a child gets his shoes when asked to do so) or it can be verbal (e.g., a child says "Can you help me?"). When a listener takes verbal action, she now becomes a speaker, and her behavior should be interpreted as such (e.g., a mand). Speakers and listeners reverse roles, often rapidly in verbal exchanges, and usually speakers and listeners are also self-listeners of their own verbal behavior. In any given verbal exchange, all of these repertoires interact with each other and with the current context and contingencies. The interaction between speakers and listeners (including self-listeners) constitutes what Skinner termed a **verbal episode**, and can be considered the basic speaker-listener unit of verbal behavior. The roles of the listener and the elements of a verbal episode will be described in more detail.

Mediator of Reinforcement

One role of a listener is to consequate a speaker's behavior, which can occur in a number of ways. Eye contact, head nods, social praise, smiles, and so on can all function as generalized S^r. But listeners do more than just directly reinforce a speaker for emitting verbal behavior; they reinforce the speaker's behavior by acting on her verbal behavior. For example, if a speaker says, "Can you hand me the remote?" the listener's nonverbal behavior of passing over the remote functions as specific reinforcement for the speaker's verbal behavior and abolishes the MO. A listener may also ignore or punish a speaker's verbal

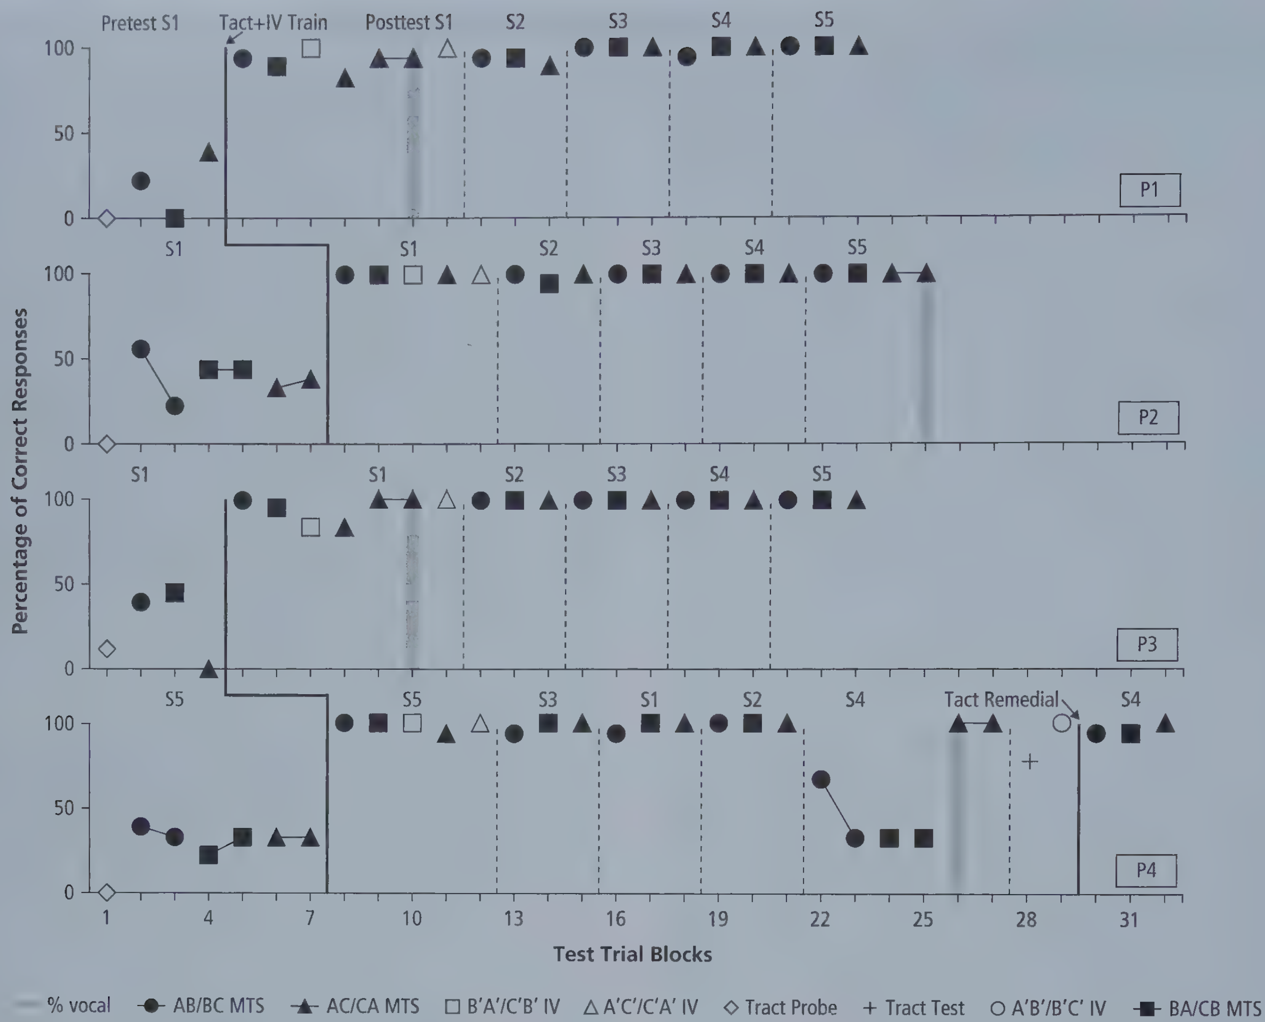

Figure 18.5 Percentage of correct responses during matching-to-sample (MTS) tasks, tacts, listener, and intraverbal tests across five sets of stimuli for 4 of the 17 participants. The closed circles, squares, and triangles represent three types of MTS tasks that constitute equivalence as measured in baseline conditions, followed by performance after tact and intraverbal training, and then across five generalization sets. The open circles and squares represent measures of emergent bidirectional intraverbal behavior.

From "Training Intraverbal Bidirectional Naming to Establish Generalized Equivalence Performance" by A. M. Jennings and C. F. Miguel, *The Journal of the Experimental Analysis of Behavior, 108,* p. 279. Reproduced with permission of John Wiley & Sons, Inc.

behavior, likely resulting in an extinction burst or decrease in responses. These types of consequences delivered by listeners shape and maintain speaking behavior, and help bring it under S^D and MO control.

Serving as an Audience

The listener also serves as a nonverbal S^D for a speaker's behavior. Skinner (1957) devotes an entire chapter to the role of the listener as an audience, and in doing so identifies three subdivisions of an audience. The first and largest subdivision is the language spoken (e.g., an English-speaking audience evokes English words). The second level involves special audiences who evoke differential responses. For example, one might use the term "reward" when talking with parents and laypersons but the term "reinforcement" when talking with behavior analysts. The third and most extensive role of the audience is to "select a subject matter" (Skinner, 1957, p. 175). We talk about different topics with different people. For example, a discussion involving sports may be reinforced by one member of a speaker's verbal community, but punished by another, and each audience acquires multiple and generative discriminative functions.

Understanding a Speaker

The most complex aspect of a listener's behavior involves what can be identified as understanding what a speaker says. Understanding on the part of a listener can be demonstrated by nonverbal or verbal behaviors. Nonverbal understanding can be

Dr. Mark L. Sundberg

Dear Mark:

Thanks for the copy of the new edition. I thought there were some excellent things in it. I like the review of Bruner. It is quite amazing how the linguists are coming around to the position of my book. They had to get around to the behavior of the speaker sooner or later, having spent centuries on how verbal behavior is understood by the listener.

The book you cited must have been my <u>Recent Issues in the Analysis of Behavior</u>, not anything to do especially with verbal behavior.

Things are going well here. I am transcribing and editing a draft of my paper at ABA for the <u>Journal of Behaviorology</u>.

All the best,

B.F Skinner

B. F. Skinner's Letter To Mark Sundberg HARVARD UNIVERSITY DEPARTMENT OF PSYCHOLOGY. Used with permission

demonstrated by a verbal stimulus that evokes a corresponding nonverbal response. For example, in standard receptive language training, a child may be shown an array of buildings and asked, "Where is the post office?" The nonverbal selection of the picture of a post office would demonstrate a type of understanding. Verbal understanding can be demonstrated by a verbal stimulus that evokes an appropriate verbal response from the listener (who is now a speaker). For example, if a tourist asks a passerby for the location of a post office, and the passerby says, "About three blocks down, on the left," understanding what the tourist asked is demonstrated by the intraverbal behavior emitted by the passerby.

The same four types of verbal discriminations previously described for intraverbal relations can be used as a framework to identify various types of nonverbal listener discriminations (Figure 18.4). In addition, there is a fifth type of verbal discrimination that is specific to listener behavior commonly termed an auditory conditional discrimination (e.g., Saunders & Green, 1999; Sidman et al., 1982). Each of these types of listener discriminations demonstrates how multiple control in the form of a conditional discrimination between verbal and nonverbal stimuli is an important aspect of listener understanding.

Speaker and Listener Verbal Episodes

Figure 18.6 presents an example of a verbal episode in which a speaker in a restaurant asks a waiter, "May I have some bread?" The sources of antecedent control are multiple: (1) an MO related to bread (MO_1), (2) the general context (the restaurant) (nonverbal S^{D}_{1}), (3) a receptive audience (the waiter) (nonverbal S^{D}_{2}); if the waiter asks, "Do you need anything else?" these (4) verbal stimuli are relevant (verbal S^{D}_{1}), and if bread is visible, that (5) nonverbal stimulus (nonverbal S^{D}_{3}) could also participate in the antecedent configuration. For the listener (the waiter), his behavior is controlled by the speaker's words, "May I have some bread?" (verbal S^{D}_{2}). The speaker's words can have multiple divergent effects on listener behavior. They can evoke a verbal response (e.g., "Yes, of course") and a nonverbal response (e.g., the waiter delivering bread), but only the delivery of bread functions as the ultimate specific reinforcement for the speaker, and changes the function of the MO to an abolishing operation (AO). Generalized S^r in this example, although encouraging, would not satisfy the MO. There can be other variables involved in this episode as well (e.g., listener MOs, respondent relations, covert behaviors).

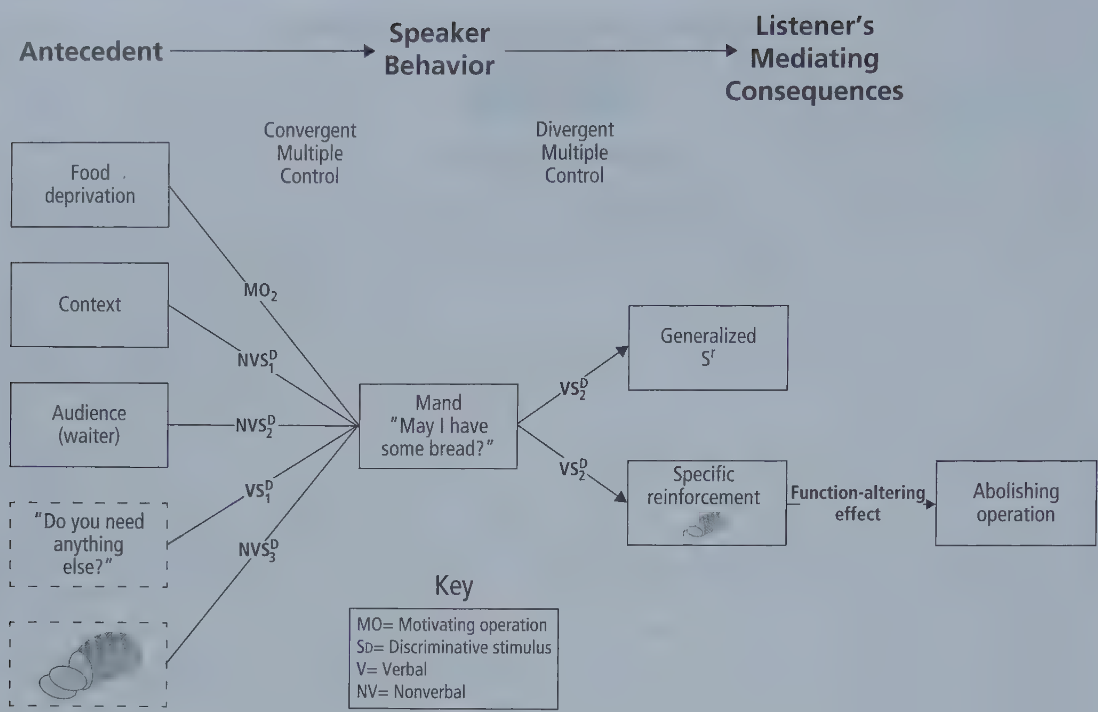

Figure 18.6 A verbal episode between a speaker and a listener.

This interaction could also generate new MOs and S^Ds (e.g., butter, a glass of wine).

Figure 18.6 also demonstrates how the same word can have different meanings for speakers and listeners, and why separate accounts are necessary. In this example, the same word "bread" and its nonverbal referent are involved for each party, but the word "bread" appears in different positions in the individual four-term contingencies affecting the speaker and listener. For the speaker, "bread" is a response, but for the listener, "bread" is a stimulus. In addition, the word has different functions for each participant. For the speaker, "bread" is a response in a mand relation, but for the listener "bread" is a verbal S^D that evokes a nonverbal discrimination. Thus, what the word "bread" means for the speaker is not the same as what the word "bread" means for the listener, despite having the same formal properties and nonverbal linguistic referent.

Emergent Listener Relations

A listener is an active responder, and new listener relations can emerge through the process of stimulus and response generalization. In addition, new relations can emerge through generative processes produced by the combinations of previously acquired skills. Several studies have demonstrated that novel listener behaviors can emerge from direct training on speaker relations (e.g., Byrne, Rehfeldt, & Aguirre, 2014; Cuvo & Riva, 1980; Ingvarsson, Cammilleri, & Macias, 2012; Lowe, Horne, Harris, & Randle, 2002; Petursdottir & Carr, 2011; Petursdottir & Haflidadóttir, 2009). For example, Ingvarsson et al. (2012) showed that direct intraverbal training was sufficient to generate emergent listener discriminations for children with autism.

Common Bidirectional Naming (C-BiN)

The merging of speaker and listener cusps is the foundation of BiN. Once a child has acquired the basic echoic, tact, listener, and self-listener cusps, the prerequisite repertoires for C-BiN are established and a novel word acquired (or observed) as a tact can immediately generate a listener relation without further training (i.e., symmetry, mutual entailment). Several studies have demonstrated this type of bidirectional naming and its effects on emergent listener behavior (e.g., Gilic & Greer, 2011; Greer & Ross, 2008; Horne & Lowe, 1996; Miguel & Kobari-Wright, 2013).

Conditioning the Behavior of the Listener

Emergent listener behavior can also occur through the behavior of a speaker who provides instructions (rules) that condition the immediate or future behavior of a listener (Schlinger, 2008b; Skinner, 1957, 1969). A speaker's words can alter the functional properties of other words, objects, and events for a listener, but not until those stimuli are encountered (Schlinger & Blakely, 1994). For example, if a speaker says, "Don't go to Bill's Restaurant—it's horrible," any stimulus in that equivalence relation can acquire an emergent evocative effect if encountered. Bill's Restaurant may now evoke avoidant behavior or the tact "horrible." In addition, the restaurant, its owner, or patrons may now evoke behavior in equivalence relations with horrible things, which might include aggression or property destruction (e.g., vandalism). These transformation of function effects demonstrate the generative effect of instructions, and show the potential impact that words can have on behavior.

AUTOCLITIC VERBAL BEHAVIOR

In the process of acquiring language, a child learns to listen to the words of others. Along the way, the child also learns to listen and react to her own words. She may self-edit, qualify, order, negate, or elaborate on her words. This is an important and complex secondary type of verbal behavior that is shaped and reinforced by listeners in a speaker's verbal community. For example, a supervisor may pause briefly before saying to a staff member, "That was good." What might be the behavioral effects of the pause? Does it have any special meaning to a listener? The pause can produce a verbal stimulus that accompanies what the listener hears, and it can change the way a listener reacts to what he hears. Speakers manipulate their own verbal behavior, often accidentally or unknowingly, because such behavior is reinforced by listeners. Skinner terms this secondary verbal behavior autoclitic behavior.

The **autoclitic** relation involves "two systems of responses, one based upon the other. The upper level can only be understood in terms of its relation to the lower level" (Skinner, 1957, p. 313). The upper level may be described as a speaker's verbal behavior about her own lower level verbal behavior. Michael (1991, 1992) suggested that these two levels of responses be identified as *primary verbal behavior* as the lower level and *secondary autoclitic behavior* as the upper level. A primary verbal response constitutes any of the verbal operants (e.g., mand, tact, intraverbal, textual), and a secondary autoclitic response is controlled by "some feature of the primary verbal operant or by its controlling variables" (Michael, 1992, p. viii). For example, a primary response such as "The ice is solid" may be accompanied by a secondary response, "I think," that informs the listener of the tenuous nature of the primary tact. Autoclitic behavior is helpful to listeners who may prompt a speaker to identify the sources of control for what she says, as in "Did you test the ice?" The autoclitic response tells the listener more than just the primary response on its own, and listeners reinforce speakers for this extra information.

Michael (1991) suggests that not all of a speaker's secondary verbal behavior has an autoclitic function. Some of a speaker's response to her own verbal behavior consists simply of more primary verbal behavior. For example, covert verbal behavior regarding an upcoming meeting may evoke self-intraverbals or self-mands regarding that meeting. Michael (1991) identifies this type of response to one's own verbal behavior as *simple secondary verbal behavior*. There are several ways to distinguish between secondary autoclitic responses and simple secondary responses. For example, a secondary autoclitic response cannot affect behavior on its own; it must involve some aspect of a primary response. Simple secondary behavior, requires a strict temporal relation between the primary response and the secondary response, with the primary response always occurring first and generating the relevant verbal S^Ds that evoke the secondary verbal behavior. The autoclitic relation differs in that the primary response and secondary autoclitic response can occur in any order, or simultaneously (e.g., "I think that's the right exit," "That's the right exit, I think," or slowly emitting "right"). Peterson and Ledoux (2014) suggested that secondary autoclitic relations be further classified as autoclitic mands and autoclitic tacts.

Autoclitic Mand

The **autoclitic mand** is a type of secondary autoclitic behavior that has the same defining features as a primary mand (responses controlled by an MO and specific reinforcement), except the autoclitic mand is secondary verbal behavior that enjoins a listener to take some specific action regarding the primary response, and autoclitic behavior is reinforced by the listener's action. For example, a speaker who says, "Believe me, they are wrong," is blatantly manding to the listener with "believe me" to verbally accept as fact, without challenge, her statement "They are wrong." The autoclitic mand can take any form, accompany any type of verbal interaction, and range from subtle to obvious.

Autoclitic Tact

An **autoclitic** tact is a type of secondary verbal behavior that is controlled by some nonverbal feature of the primary response or its controlling variables, and the autoclitic response informs the listener of that feature. This behavior is reinforced by listeners who provide generalized S^r. For example, a speaker may say, "I'm sure it's safe," where the secondary autoclitic response "I'm sure " is a tact of the strong source of control for "it's safe." Skinner (1957) identified several types of autoclitic tacts. A *descriptive autoclitic tact* is controlled by the nonverbal properties of the antecedent events and their relation to the primary response. There are several types of descriptive autoclitics. For example, an autoclitic tact of strength could be observed in a speaker who might have a tendency to say, "That's the right house" (a primary response), and covertly tacts the strength of the nonverbal stimulus control (a secondary autoclitic response) and tags on, "I'm sure," before "That's the right house." "I'm sure" is a descriptive autoclitic tact that informs the listener of the strength of the primary relation and as a result alters the listener response to "That's the right house." The listener reinforces the speaker's behavior because he is benefited by this additional information.

Quantifying autoclitic tacts inform the listener of the range of application of a primary response. For example, a speaker may tag on the autoclitic tact "some" to the primary tact "Behavior problems are caused by attention." The autoclitic "some" informs the listener that the whole statement that follows is restricted in its range. If "all" had been tagged on to the primary response, the listener would behave differently. *Relational autoclitic tacts* inform the listener of agreement between aspects of the primary responses. For example, possessive relations indicated by an *'s* can be tagged to a noun, as in the "supervisor's recommendation," and function as a tact of the source of control for the recommendation, and as a tact of the agreement between the source and the recommendation. Skinner suggested that autoclitic relations play a causal role in complex verbal activities involving grammar, syntax, composition, grouping, ordering, punctuation, predication, and so on (e.g., Palmer, 2016).

Intraverbal Autoclitic Frames

An intraverbal autoclitic frame facilitates the relation between words in a given utterance by providing order, agreement, grouping, and composition of larger units of verbal behavior. Moore (2008) describes an autoclitic frame as "conventionally prescribed formats of sequences for emitting verbal behavior, as in subject-verb-object or actor-action-object sentences. These frames may become very generalized, such that they come to be applied in many other situations than the original" (p. 208). Skinner (1957) provides the following example of an autoclitic frame:

> If (a boy) has acquired a series of responses such as *the boy's gun, the boy's shoe*, and *the boy's hat*, we may suppose that the partial frame *the boy's* _____ is available for recombination with other responses. The first time the boy acquires a bicycle, the speaker can compose a new unit *the boy's bicycle*. . . . The relational aspects of the situation strengthen a frame, and specific features of the situation strengthen the responses fitted into it" (p. 336).

Palmer (2016) notes "many of the structural properties of verbal behavior that so excite the linguist arise, at least in part, from the prevalence of intraverbals and intraverbal control. In particular, autoclitic frames and grammatical tags are largely intraverbal" (p. 101). Speakers must acquire these intraverbal autoclitic frames and tags because they play an important role in the effective execution of verbal behavior. Very little research on autoclitic frames is available, but some has begun to emerge (e.g., Luke, Greer, Singer-Dudek, & Keohane, 2011; Martins, Hübner, Gomes, Pinto Portugal, & Treu, 2015; Speckman, Greer, & Rivera-Valdes, 2012).

APPLICATIONS OF SKINNER'S (1957) ANALYSIS OF VERBAL BEHAVIOR

One of the most developed applications of Skinner's work can be found in the behavioral treatment of autism or other types of intellectual disabilities.[4] Linguistic problems are often the primary handicapping conditions of those diagnoses, and effective language assessment and intervention strategies are essential for treatment programs. Joe Spradlin was the first to publish an application of the concepts from *Verbal Behavior* to the communication needs of the intellectually disabled. He created the *Parsons Language Sample* (1963), which was an assessment tool based on the verbal operants. Spradlin was also instrumental in the early research and development of language intervention programs based on verbal behavior (e.g., Spradlin, 1966). Jack Michael was one of the first professors to offer a full course using Skinner's (1957) book *Verbal Behavior*, and he spearheaded the further development of Skinner's analysis of verbal behavior (see Box 18.3).

BOX 18.3

Jack Michael and Skinner's Analysis of Verbal Behavior

Jack Michael began teaching behavior analysis in 1955 at the University of Kansas. He used Skinner's (1953) *Science and Human Behavior* as the textbook for the course. In that book, Skinner mentioned his upcoming book *Verbal Behavior* in a footnote (p. 210). Jack contacted Skinner regarding the book, and Skinner sent him an early version of *Verbal Behavior*. Jack began to incorporate verbal behavior content into his courses. After the book became available, Jack developed a full course on verbal behavior and taught that course nearly every academic year until his retirement in 2003. He maintained, like Skinner (1953), that an analysis of verbal behavior was essential for a complete account of complex human behavior (e.g., Michael, 1984).

One of Jack's primary goals as a teacher was to impart to students the verbal repertoires necessary to precisely use the concepts and principles of behavior analysis to analyze behavior, including verbal behavior, in any context (Michael, 1995, 2004). In the process of teaching others, he was constantly advancing his own understanding of Skinner's writings while refining various concepts along the way (e.g., motivating operations, positive and negative reinforcement, automatic reinforcement, topography-based and selection-based verbal behavior, duplic and codic relations).

Applied research on verbal behavior was important to Jack, but it was slow in developing, despite Skinner's (1957) prediction that "[t]he formulation is inherently practical and suggests immediate technological applications at almost every step" (p. 12). In 1976, Jack started offering a graduate course at Western Michigan University titled "Verbal Behavior Applications." That course inspired many students, especially those needing theses or dissertations, to conduct verbal behavior research. The Midwestern Association for Behavior Analysis (MABA) convention provided contingencies to present the research, and a verbal community arose that eagerly supported verbal behavior research.

Jack and W. Scott Wood were instrumental in starting the Verbal Behavior Special Interest Group (VB SIG). They co-chaired the first meeting, which was held at the 1977 MABA convention. Skinner attended and participated in the discussions, as did many other prominent behavior analysts. It was suggested that an outlet for verbal behavior research and other instructional material was needed. Under Jack's direction, the VB SIG established a newsletter, the *VB-NEWS*, which ultimately became the journal *The Analysis of Verbal Behavior*. Thanks to Jack's relentless dedication to understanding, teaching, advancing, and applying Skinner's analysis of verbal behavior, we now have a robust body of conceptual and empirical research, and many highly successful clinical applications.

APPLICATIONS TO LANGUAGE ASSESSMENT AND INTERVENTION

Behavior analysis provides three major contributions to language assessment and intervention programs for individuals with special needs: (1) applied behavior analysis technology, (2) a behavioral analysis of human development, and (3) a behavioral analysis of language.

Applied Behavior Analysis (ABA) Technology

Behavioral technology provides teachers, speech-language pathologists (SLPs), parents, and others with the necessary procedures and strategies to assess and teach language skills to those who need formal instruction (e.g., Leaf & McEachin, 1999; Lovaas, 1987, 2003; Maurice, Green, & Luce, 1998; Romanczyk & McEachin, 2016). Effective use of behavioral procedures requires specific training and supervision. For example, staff must know when and how to use reinforcement, extinction, prompting, fading, and so on. The content of the current book describes the essential features of ABA, as do a number of other behavior analysis textbooks (e.g., Malott & Shane, 2013; Martin & Pear, 2015; Miltenberger, 2016; Sulzer-Azaroff, Mayer, & Wallace, 2013).

A Behavioral Analysis of Human Development

The development of language and social skills of typically developing children provides a valuable guide and framework for working with children with language delays. Knowing what skills to teach and when those skills appear in typical language development is an important component of establishing and sequencing a language intervention program. Behavior analysis has a long history of child development research, beginning with the books by Bijou and Baer (1961, 1965, 1967). Their work provides a behavioral analysis of how children learn and develop skills throughout their early childhood. There is a dedicated journal (*Behavioral Development Bulletin*) and numerous extensions and applications of a behavioral approach to human development (e.g., Greer & Koehane, 2005; Morris et al., 1982; Novak & Pelaez, 2004; Rosales-Ruiz & Baer, 1997; Schlinger, 1995).

A Behavioral Analysis of Language

Skinner's (1957) analysis of verbal behavior provides a framework for language assessment and intervention. A verbal behavior assessment program involves identifying the strength of the elementary verbal operants, listener skills, self-listener skills, multiply controlled responding, and speaker-listener interactions in a developmentally sequenced fashion. Intervention is based on the assessment results and focuses on establishing missing or impaired speaker or listener skills through the use of ABA teaching procedures. Several publications are now available that provide detail on how to apply Skinner's analysis of verbal behavior in working with individuals who have language delays (e.g., Barbera & Rasmussen 2007; Carr & Miguel 2012; Dixon, 2014; Greer & Ross, 2008; LeBlanc & Dillon, 2009; McGreevy et al., 2012; Partington, 2006; Schramm, 2011; Sundberg, 2014, 2016b; Sundberg & Michael, 2001; Sundberg & Partington, 1998; Weiss & Demiri, 2011).

The Importance of Language Assessment

Parents and pediatricians usually monitor a child's acquisition of language, noting important milestones while watching for discrepancies. Language delays are associated with a variety of diagnoses (e.g., autism, communication disorders) and early identification is valuable. If a child cannot communicate with words, negative behavior (e.g., tantrums, aggression, social withdrawal) may serve the communication function. When a child's language skills fail to develop, or are impaired in some way, professional assistance should be obtained, such as services from an SLP, behavior analyst, or psychologist.

A language assessment for a person with language delays has three primary goals: (1) to identify the nature of the delay or problem, (2) to compare the person's performance with expected norms, and (3) to provide guidance for an appropriate intervention program if necessary. Each type of speaker and listener behavior needs to be assessed independently and in various combinations (e.g., C-BiNs, equivalent and non-equivalent relations) to obtain baseline levels of performance and to identify the direction of an intervention program. The goal is to determine what a child can and cannot do (e.g., mand, echo, listen, tact, demonstrate generative learning). The value of assessing each of the speaker and listener domains, and the interaction between them, is that it is common to encounter language-delayed children who can emit a word as one type of verbal behavior (e.g., a tact) but not as another (e.g., a mand).

A variety of standardized language assessments are available, but none provide measures of all of the verbal operants and listener skills (Esch, LaLonde, & Esch, 2010). However, several criterion-referenced language assessments are available that do measure each of the verbal operants and listener repertoires (e.g., Dixon, 2014; McGreevy et al., 2012; Partington, 2006; Partington & Sundberg, 1998; Spradlin, 1963; Sundberg, 1983, 2014; Sundberg & Partington, 1998; Sundberg et al., 1979). These assessments are framed by the elementary verbal operants, listener behavior, various combinations of speaker and listener behavior, and perceptual behavior. In the following sections, early language assessment and intervention strategies will be described for each of the individual speaker and listener domains.

Mand Assessment

Assessing a child's mand repertoire involves identifying the degree to which MOs control verbal responses. The mand classification system previously described can guide the assessment process. Specifically, the distinctions between the types of MOs (i.e., UMO, CMO-T, CMO-R) and their evocative effects on verbal behavior can be assessed. For example, does the child emit a mand when deprivation UMOs are at strength (e.g., saying "milk" when she wants milk) or when aversive stimuli function as UMOs (e.g., when it is cold, saying "Let's go in"). A similar process is necessary for learned MOs such as the CMO-T (e.g., manding for a missing toy) and the CMO-R (e.g., manding to fix

a broken toy). In addition, the delivery of specific reinforcement should abolish (AO) the CMO-R (e.g., the toy is fixed) and this effect should be assessed.

Mands can also be assessed across MOs relevant to the different parts of speech (e.g., MOs related to action, location, possession) and in social interactions between speakers and listeners (e.g., manding to peers). Also, Skinner's nine types of mands (Figure 18.3) can provide a further quantification of the different MOs that control mands for a specific person. Mands involving multiple variables should also be assessed, such as those involving multiple MOs (e.g., manding "I want scissors and Play-Doh"), MOs accompanied by nonverbal S^Ds (e.g., "I want that red one"), MOs accompanied by verbal S^Ds (e.g., manding for a specific video game after a salesperson's pitch), and MOs accompanied by both verbal and nonverbal S^Ds (e.g., asking a waiter for bread).

Barriers to Manding

An important component of an intervention program is an analysis of the language, learning, and social barriers demonstrated by a child during verbal interactions with others (Sundberg, 2014). The mand is more susceptible to interference from barriers than are the other verbal operants because of the mand's relation to MOs and specific reinforcement. These variables are powerful and can quickly evoke and shape negative behavior. For example, a child's scream may immediately evoke eye contact and attention from an adult, and as a result screaming behavior increases and comes under MO and S^D control. These naturally occurring contingencies may be more efficient than the carefully nurtured and programmed contingencies offered in a structured intervention program. There are several common barriers involving MOs and specific reinforcement, such as demand weakening the MO, quick satiation, competing MOs and S^Ds, response forms inconsistent with the MO, and generalized CMO-Rs dominating behavior.

Mand Intervention

If a toddler fails to develop a mand repertoire, specific intervention may be necessary. Without words, signs, or icons as mands, the probability of negative behavior (e.g., tantrums) functioning as mands increases. The initial focus of an intervention program for nonverbal learners is usually on both establishing acceptable mand forms (preferably speech, but signs and icon selection can also be effective) and reducing existing forms of negative behaviors as mands.

Response Form

An important aspect of mand training for a nonverbal child is to establish a reliable response form that can produce the best possible effects on a listener. In early mand training there are three possible choices: speech, sign language, and icon-selection systems (in some special cases, written words can also be used as a fourth option). The primary focus should be on speech as a response form. However, if a child fails to acquire speech, sign language and icon-selection systems can work as mand forms (e.g., Frost & Bondy, 1994; Sundberg & Partington, 1998). Determining which form is most appropriate for an individual child depends on a variety of factors that should be carefully considered (Bondy, 2012; Carbone, Sweeney-Kervin, Attanasio, & Kasper, 2010; Sundberg, 1993a; C. T. Sundberg & Sundberg, 1990; Tincani, 2004).

Using MOs for Instructional Purposes

Teaching children with absent or impaired mand repertoires requires special skills on the part of caregivers. In addition to basic ABA knowledge, adults must be able to identify and control the different MOs and related specific reinforcement as part of their teaching skills. If the relevant MO is not at strength, early mand training is impossible. MOs are often difficult to control because they can vary in strength across time, be fleeting, have an instant or gradual onset or offset, and combine or compete with other MOs and S^Ds. In addition, too high a response requirement placed on a child may quickly weaken an MO (Alling & Poling, 1995).

Two general methods are used for identifying and controlling the value change of MOs for mand training: (1) capturing the MO value change as it occurs naturally and (2) creating the MO by generating some change that alters the value of a consequence (Michael, 1993; Sundberg, 1993b, 2013). Capturing motivation in the natural environment can be accomplished by observation of collateral behaviors that may be evoked by an MO (e.g., looking at a certain toy). Collateral behaviors provide insight as to the presence of a private MO, and thus an opportunity to teach a new mand to a child (e.g., "ball"). Creating motivation requires an adult to make some direct change (e.g., presenting a desired iPad without turning it on) that increases the value of some other change (e.g., turning on the iPad). The onset of this MO value change can be used to establish a new mand relation (e.g., "iPad on").

Capturing and Creating UMOs

The deprivation-based UMOs (e.g., food, drinks) are often an easier place to start for early or difficult learners because of the powerful evocative effects of these MOs (e.g., teaching "cracker" or "juice" as an early mand). UMOs can be captured for mand training purposes. For example, if a child reaches for a cracker, capture that MO and conduct a mand teaching trial. UMOs can also be created. For example, give the child some salty foods to increase the value of drinks as reinforcement. These conditions are also optimal for the implementation of pairing procedures to facilitate the development of additional behaviors, S^Ds, and forms of S^r (e.g., Esch, Carr, & Grow, 2009; Rader et al., 2014; Stock et al., 2008).

Capturing and Creating CMO-Ts

Capturing CMO-Ts in a child's natural environment can be accomplished by observing the events that increase the value of some object or event. For example, after an adult blows bubbles with a wand, a child demonstrates excitement while watching the bubbles float and pop. After they pop, the value of the wand and specific adult behavior increases, and that is the time to conduct a mand trial. Additional ways to capture MOs include the observation of established chains of behavior that are interrupted (e.g., missing toy piece), routines that are difficult (putting on

a jacket), and preferences (e.g., a certain cup). The pioneering work of Hart and Risley (1975) on incidental teaching exemplifies these teaching strategies.

CMO-Ts can be created by caregivers for language instruction as well (e.g., Albert, Carbone, Murray, Hagerty, & Sweeney-Kerwin, 2012; Hall & Sundberg, 1987; Landa, Hansen, & Shillingsburg, 2017; Oleson & Baker, 2014). For example, if a child likes to cut Play-Doh with scissors, then the presentation of Play-Doh may increase the value of scissors, demonstrated by the child's collateral behavior of reaching for scissors. The adult could block access to the scissors to control the MO and teach the mand. Establishing these mands can be accomplished by the use of prompting, fading, differential reinforcement, and transfer procedures (Sundberg & Partington, 1998).

Parts of Speech. The parts of speech provide a developmental framework for more advanced mand training. For example, in addition to mands for edible and tangible reinforcement, a child needs to learn mands for actions (verbs), for properties of objects (adjectives), for relations between objects (prepositions), and so on. All of these mands are controlled by different MOs, and each particular MO should be at strength at the moment of teaching.

Teaching Additional Types of Mands

Further direction for mand training can come from Skinner's list of nine types of mands (Figure 18.3). For example, a question is a mand controlled by an MO related to verbal information and specifically reinforced by the receipt of that information. Mands for information contribute to the burst in vocabulary growth commonly observed in toddlers between the ages of 2 and 3. These mands involve an increase in the value of the names of things and events (e.g., "What's that?") or the location of things and events (e.g., "Where's Buzz?"), while later questions may involve MOs for the function of things and events (e.g., "How do you turn it on?") or the cause of events (e.g., "How did it break?"). A growing body of research has provided support for the role of MOs in question asking and has demonstrated a variety of effective teaching procedures (e.g., Endicott & Higbee, 2006; Lechago, Carr, Grow, Love, & Almason, 2010; Lechago & Low, 2015; Shillingsburg, Gayman, & Walton, 2016; Sundberg, Loeb, Hale, & Eigenheer, 2002).

Multiple Control

MOs frequently share control with other MOs, verbal S^Ds, and nonverbal S^Ds as types of convergent multiple control. Multiple sources of control can be quite useful for establishing mands. A child's early manding may be controlled by MOs along with echoic, intraverbal, or nonverbal prompts, and through the process of differential reinforcement for higher quality responding, the response can be freed from these additional sources of control.

Teaching Extended Mands

Skinner (1957) identified several ways that mands generalize across MOs and S^Ds, and how the same MO can control different response forms (Miguel, 2017). Recent research has demonstrated methods to establish new mand forms for the same MO by using procedures from relational frame theory (e.g., Hayes et al., 2001; Murphy & Barnes-Holmes, 2009; Rosales & Rehfeldt, 2007). For example, Murphy & Barnes-Holmes (2009) established multiple types of derived mands involving "more" and "less" for three participants with autism. The study was conducted in the context of a board game involving the quantity of tokens required to be successful (more or less). These authors showed that a new mand response form could be established with a supplemental conditional discrimination training procedure that allowed for novel stimuli to become equivalent with existing mand forms. That is, the participants learned, without formal training, a new way to mand for "more" or "less."

Tact Assessment

Assessing a tact repertoire involves determining the degree to which nonverbal stimuli control verbal behavior. This is a sizable task given that the whole of the physical environment contains a massive number of nonverbal stimuli. The different parts of speech provide a frame for tact assessment because each part often demonstrates a different type of nonverbal stimulus control. Many nouns involve nonverbal S^Ds consisting of static objects, and many verbs involve nonverbal S^Ds consisting of movement, while many adjectives and adverbs involve nonverbal S^Ds generated by the properties of objects and events, and relations between them. A similar analysis can be made for the other parts of speech (e.g., prepositions, pronouns). In addition, an assessment of C-BiN relations can identify the strength of this higher order verbal operant (e.g., Greer & Ross, 2008; Miguel, 2016).

Sensory Receptors

Tacts can also be assessed across the different sensory receptors affected by nonverbal stimuli (e.g., visual, auditory, tactile)—for example, testing the tact of a cat when the target is a visual stimulus (e.g., a cat) versus an auditory stimulus (e.g., hearing a cat meow).

Multiple Control

Tacting becomes more complex when multiple variables are involved. For example, a noun-verb tact such as "The water's spilling out" involves at least two sources of stimulus control: One is a nonverbal S^D related to the water, and the other is a nonverbal S^D related to the movement of the water. Important information regarding a tact repertoire can be obtained by sampling the arrangement of various nonverbal stimuli corresponding to the different parts of speech (e.g., possessive-adjective-noun, subject-verb-noun). In addition, nonverbal S^Ds can combine with MOs and verbal S^Ds as types of convergent multiple control. For example, a child may emit the name of a video game she sees due to both an MO and a nonverbal S^D, making the response part mand and part tact.

An important aspect of tact assessment involves identifying the degree to which nonverbal stimulus generalization occurs. The four types of tact extensions provide a framework for assessing a person's skill in this area. In addition, the ability

to tact private events is a component part of a tact repertoire and can be measured by the occurrence of collateral behavior (e.g., limping) or public accompaniment (e.g., a bruise).

Tact Intervention

Learning to tact features of the physical environment is a cornerstone of early language acquisition. Once a tact repertoire is acquired, it can benefit a child in many ways. For example, tacting can facilitate listener behavior and the acquisition of other forms of verbal behavior such as mands, intraverbals, C-BiNs, equivalence classes, and relational frames (Horne & Lowe, 1996; Jennings & Miguel, 2017; Petursdottir & Carr, 2011; Sundberg, 2015). If a tact repertoire does not begin to develop for a toddler, intervention may be necessary. Teaching a child to tact is more straightforward than teaching a child to mand, because the antecedents that control the tact are more observable, measurable, quantifiable, and controllable than MOs. In addition, tacts are consequated by easily manageable and portable generalized S^rs, whereas the specific reinforcement of the mand requires having the right reinforcer at hand.

The goal of a tact intervention program is to establish a fluent and generative tact repertoire that is functional for the child, and integrated with the other speaker and listener repertoires. A tact program for a child depends on the results of an assessment of her existing tact repertoire, along with the other verbal operants and related skills, as well as possible barriers to tact acquisition (Sundberg, 2014). Once these data are obtained, the tact classification system, the different parts of speech, and ABA teaching procedures can provide a framework and guide for an intervention program. The response form for tacts can be spoken words, signs, written stimuli (including Braille), and, under some circumstances, icon selection. Tacts should also be established across the different sensory receptors affected by nonverbal stimuli (e.g., tactile, gustatory). A number of language curricula are available that contain the core elements of a tact intervention program (e.g., Barbera & Rasmussen 2007; Leaf & McEachin, 1999; Lovaas, 2003; Maurice et al., 1996; Sundberg & Partington, 1998).

Multiple Control

Toddlers begin to emit two-word utterances involving novel combinations of nouns and verbs, and other parts of speech, around 2 years of age (e.g., Brazelton, & Sparrow, 2006). For a child who fails to acquire noun-verb combinations or other types of multiple responses (e.g., adjective-noun), teaching the skill involves arranging multiple forms of nonverbal stimulus control (e.g., a ball rolling down a ramp) while prompting the child to tact the object and its movement (e.g., "ball rolling"), fading prompts, and reinforcing the highest quality responses. These types of multiple tacts, once acquired, should be generalized, extended, and framed with the child's other verbal and nonverbal activities. When a child's verbal repertoire reaches the point where novel multiple antecedent stimuli evoke corresponding multiple responses, a new cusp has been achieved.

True Language

Also around 2 years of age is the developmental period at which "true" language has been said to occur (e.g., Hayes et al., 2001; Hockett, 1960; Horne & Lowe, 1996; Malott, 2003). Interestingly, that is also about the developmental point where C-BiN (Horne & Lowe, 1996), equivalence relations (Sidman, 1994), relational framing (Hayes et al., 2001), and joint control (Lowenkron, 1998) begin to emerge. True language may be the point at which these powerful behavioral cusps begin to demonstrate their generative effects

Tacting Private Events

Teaching a child with language delays to tact stimuli arising within her body can be difficult. A child's collateral behavior is the most common method for identifying the presence of a private event. Facial expressions, pauses, body movement, particular words, and certain phrasing have the power to "give away" a private event such as an eagerness, unwillingness, or apathy. Collateral behavior, such as a child holding her stomach, can be used as a teaching opportunity to establish the tact "sick" because the relevant sources of private control are present, allowing for the use of transfer of stimulus procedures. Public stimuli can also accompany a private event (e.g., blood) and provide the observer with a teaching opportunity.

Duplic and Codic Assessment

Assessing the strength of verbal and nonverbal behavior controlled by verbal S^Ds can be organized by the technical distinctions between the duplic, codic, intraverbal, and listener relations. The duplic repertoires (echoic, motor imitation, copying text) are the simplest of the verbal operants to assess because a finite number of units compose each of these atomic repertoires (Alessi, 1987; Palmer, 2012). For example, measuring the strength of an early echoic repertoire can be accomplished with a one-page form (Esch, 2014). Codic relations (textual and taking dictation) are also easy to assess but involve additional skills such as letter discriminations and phonetics. The intervention section only contains duplic applications. A presentation of the codic applications (reading, writing, and spelling) is beyond the scope of the current chapter.

Duplic Intervention

The ability to duplicate the actions and sounds of others plays a critical role in the acquisition of language, social behavior, and generative learning capabilities (e.g., Baer, Peterson, & Sherman, 1967; Greer & Ross, 2008; Horne & Lowe, 1996; Lovaas, 2003; Lowenkron, 1998; Palmer, 2012; Poulson, 2003). For example, imitating an adult playing peek-a-boo allows for specific back-and-forth interactions between the infant and adult. These interactions can generate direct and automatic reinforcement that further establishes other aspects of an imitative repertoire. A generalized imitative repertoire is an important behavioral cusp because it allows a child to easily learn new behaviors without direct teaching or a reinforcement history (e.g., how to put on socks or connect train tracks). Motor imitation can also have a linguistic function (relating to sign language or gestural communication), and when it does, it can be classified as duplic behavior and serve a verbal function that is parallel to the echoic relation. If duplic behavior fails to develop for an infant-toddler, intervention may be necessary.

Teaching Motor Imitation (Relating to Sign Language)

Many nonvocal children with disabilities have been successful in acquiring sign language as a response form when motor imitation is easier to establish than echoic skills. The first goal of a formal program is to teach the child to copy simple motor behaviors emitted by others. Establishing this repertoire can be accomplished with standard ABA procedures. For children who need further assistance, another method is to place an imitative response within a mand frame, that is, combine the motor S^D with an MO and specific reinforcement for training purposes. For example, if a child demonstrates a strong MO for music, an imitative trial (e.g., tapping an arm as the sign "music"), along with physical prompts, can be conducted while that MO for music is strong, allowing for a momentarily strong form of specific reinforcement to be utilized as a teaching tool (Sundberg & Partington, 1998).

Teaching Echoic Behavior

A child's ability to echo words on command is one of the most important measures of her potential for language acquisition (e.g., Lovaas, 1977). The echoic is valuable because it can be used to establish mand, tact, intraverbal, and listener skills. However, a person's inability to echo words presents a major barrier to future language development, and thus is often a key component of early intervention programs (e.g., Leaf & McEachin, 1999; Lovaas, 2003; Ross & Greer, 2003; Sundberg & Partington, 1998). An echoic repertoire can be established with the use of ABA teaching procedures. However, for those who struggle with learning to echo others, the mand frame procedure described for imitation training can also be used with echoic behavior.

Automatic Reinforcement

Echoic behavior can also be established by pairing a word with existing forms of reinforcement. For example, if just prior to pushing a child on a swing, the word "swing" is emitted by an adult, the word "swing" may eventually become an S^r. Research has shown that this pairing procedure can increase the rate of a child's vocal play and result in the emission of targeted sounds under echoic control (e.g., Esch et al., 2009; Rader et al., 2014; Stock et al., 2008; Sundberg et al., 1996). Children who are having difficulty acquiring an echoic repertoire may benefit from a combination of these procedures, as well as the use of sign language or a selection-based icon system.

Listener Assessment

A listener assessment can be framed by the parts of speech and the five types of verbal discriminations previously described for listeners. In addition, an assessment of self-listener skills is essential (Esch, Esch, McCart, & Petursdottir, 2010; Greer & Ross, 2008). Measures should also be taken to assess a child's ability to serve as an audience, mediate reinforcement, and demonstrate emotional listener responding.

Simple Verbal Discriminations

The assessment of the strength of simple verbal discriminations for a listener involves determining if verbal stimuli reliably evoke a corresponding nonverbal response. For example, when asked to "walk" the child walks, and when asked to "run" the child runs.

Auditory Conditional Discriminations

An auditory conditional discrimination is more complex because it involves multiple stimuli and multiple responses. The stimuli include both a verbal S^D (e.g., "Touch shoe") and a nonverbal S^D (e.g., a picture of a shoe) in an array of other stimuli. The responses include both scanning the array of nonverbal stimuli and emitting a nonverbal section response (e.g., pointing to the shoe). The assessment of this repertoire would involve sampling various combinations of the parts of speech in increasing levels of verbal and nonverbal complexity (e.g., Dunn & Dunn, 2007; Sundberg, 2014).

Compound Verbal Discriminations

The assessment of listener behavior controlled by compound verbal stimuli involves determining if multiple words collectively generate a new S^D in a listener discrimination task. For example, if the target is to teach a child to discriminate between red and green vegetables and red and green fruits presented in an array, first test each element individually (e.g., "Can you find some red things?" "Can you find some fruits?"), then present combinations of the target verbal stimuli (e.g., "Can you find a green vegetable?) to determine if the compounding of the stimuli evokes a more specific selection response.

Verbal Conditional Discriminations

In a VC^D involving listener behavior, two separate conditional discriminations are required. The first occurs in the antecedent event where one verbal stimulus alters the evocative effects of another verbal stimulus in the same antecedent configuration. For example, in a listener discrimination involving the verbal stimulus "Which one can't you wear?" and an array of nonverbal stimuli (e.g., shirt, ball, computer), the reinforcement history related to the word "can't" alters the discriminative function of the word "wear," allowing it to function as a new S^D that participates in a second conditional discrimination involving the comparison array. In that second conditional discrimination, the shirt is established as an S^Δ and the ball and computer are established as S^Ds. Contrasting "can't" with "can" embedded in the phrase will determine if a VC^D is occurring. The assessment of a listener's VC^D repertoire can be quite complex, but would involve sampling various combinations of the parts of speech in increasing levels of verbal and nonverbal complexity (e.g., Devine et al., 2016; Smith et al., 2016; Sundberg & C. A. Sundberg, 2011).

Verbal Function-altering Effect

For a listener, the function-altering future effect involves a change in the evocative effect of a nonverbal stimulus encountered at some point in the future (Schlinger & Blakely, 1994). For example, when a child is given a certain instruction by a parent involving a future nonverbal event, such as "When

the commercial comes on, go brush your teeth," the effects of the commercial as a nonverbal S^D can only be determined later when a commercial comes on. The assessment of this repertoire would involve presenting a variety of these types of verbal instructions and nonverbal contexts.

Listener Intervention

If an infant or toddler fails to demonstrate early listener skills, there are a variety of intervention programs and materials that have produced successful results (e.g., Leaf & McEachin, 1999; Lovaas, 2003; Maurice et al., 1996). Early listener discrimination skills should be established simultaneously with tacting skills (e.g., Petursdottir & Carr, 2011). For example, while teaching a child to tact a shoe, also ask the child to select a shoe from an array. This mixed verbal behavior teaching format (Sundberg & Partington, 1998) consists of interspersing speaker and listener teaching trials and can help establish generative C-BiN repertoires (Greer & Ross, 2008; Horne & Lowe, 1996).

Learning to be a listener involves the capability to discriminate between words (or signs, text, etc.), especially when they appear in novel combinations, in different nonverbal environments, and under different MOs. The five types of verbal discriminations can provide some organization to the process of teaching a child with autism or other intellectual disabilities to comprehend words and sentences as a listener.

Simple Verbal Discriminations

Teaching simple verbal discriminations to a listener involves establishing different nonverbal behaviors under the control of different verbal stimuli. For example, teaching a child to clap when someone says "clap" and to jump when someone says "jump" involves a discrimination between words. Establishing these skills can be accomplished with ABA teaching methodology.

Auditory Conditional Discriminations

A common listener training procedure (also termed receptive labeling) involves asking a child to identify objects, actions, properties, locations, and so forth, by emitting some form of selection behavior (e.g., upon hearing "Where's the nurse?" a child selects a picture of a nurse from a comparison array). A critical component of developing auditory conditional discriminations is the configuration of the array containing the target item or activity. Initially, the array should be clear and simple and contain distinct items (e.g., a banana and a cat). Once a child acquires these beginning discriminations, training should systematically progress to more complex verbal stimuli and arrays. As with the tact, the different parts of speech can serve as a classification and curriculum guide for listener conditional discrimination training, and a number of teaching materials and programs are available for developing this repertoire (e.g., Leaf & McEachin, 1999; Lovaas, 2003).

Compound Verbal Discriminations

Establishing compound verbal discriminations for a listener involves the arrangement of different parts of speech into single phrases and the manipulation of corresponding nonverbal arrays (e.g., Devine et al., 2016; Eikeseth & Smith, 2013). Teaching these types of verbal and nonverbal listener discriminations involves presenting the combination of individual words that are already in a child's listener repertoire. For example, a child may be able to respond as a listener to "wiggle" by wiggling, and "fingers" by showing an adult his fingers, but when asked "Can you wiggle your fingers?" the child cannot respond correctly. To teach this skill, imitative prompts can be used and faded, with the goal of establishing "wiggle fingers" as a new compound verbal S^D that evokes finger wiggling. Eventually new nouns and verbs can be added to the instruction (e.g., wiggle toes, point your finger). Matrix training provides an efficacious and generative format for establishing these types of discriminations.

Verbal Conditional Discriminations

Teaching a child to emit VC^Ds as a listener can be accomplished with a procedure identified as listener responding by function, feature, and class (LRFFC) (DeSouza et al., 2019; Smith et al., 2016; Sundberg, 2014; Sundberg & Partington, 1998). In LRFFC training, a child is asked to identify nonverbal stimuli when given verbal S^Ds based on the things that one can do with an object (e.g., ride it, wear it), its features or attributes (e.g., wheels, sleeves), or its class or category (e.g., vehicles, clothing). Elements of these different verbal stimuli can be combined and contrasted to establish the necessary VC^Ds. For example, given a scene of a farm, an adult asks a child a series of LRFFC questions such as "Which animal eats hay?," "Who grows the hay?," "Which animal lays eggs?," and "Who cooks eggs?" The different parts of speech can be used as a framework for LRFFC training procedures. A major advantage of this type of listener training is that it establishes VC^Ds that can also be used to teach intraverbal behavior.

Verbal Function-altering Effect

Teaching a child to respond to verbal stimuli that change the effects of future nonverbal stimuli can be accomplished by gradually increasing the delay between the initial verbal stimulus and contact with the targeted nonverbal event. For example, if the target relation involves telling a child, "When your father gets here show him your award," training could begin with a brief delay between the instruction and the arrival of the father, and then gradually increase the delay. Once acquired, new instructions along with new nonverbal contexts should be introduced to develop this advanced form of listener behavior.

Intraverbal Assessment

Intraverbal relations are perhaps the most difficult of the elementary verbal operants to assess and quantify. Although early intraverbal behavior emitted by children is usually straightforward, intraverbal relations quickly become more complex as multiple verbal stimuli and multiple responses participate in verbal episodes with listeners. The four types of verbal discriminations, along with the parts of speech, and multiple control involving nonverbal S^Ds and MOs, can provide a framework for intraverbal assessment (Devine et al., 2016; Sundberg, 2014, 2016a; Sundberg & C. A. Sundberg, 2011). In addition, an assessment of I-BiN repertoires can identify the strength and effectiveness of this higher order verbal operant (Greer & Ross, 2008; Miguel, 2016).

Simple Verbal Discriminations

Many examples of simple intraverbal discriminations can be sampled during an assessment (e.g., songs, fill-in-the-blank games, common associations). Performance on these types of verbal tasks can be compared to the performances of typically developing children for a developmental perspective.[5]

Compound Verbal Discriminations

The assessment of a speaker's intraverbal behavior controlled by a compound verbal stimulus is similar to the process for the listener, except without the presence of nonverbal stimuli. For example, when the question "Can you tell me a red fruit?" is presented without any pictures and a child says "apple," and when asked, "Can you tell me a red vegetable?" she says "pepper," this constitutes a measure of intraverbal behavior controlled by a compound verbal S^D.

Verbal Conditional Discriminations

The assessment process for intraverbal behavior controlled by verbal conditional discriminations is similar to the process for the listener, except the strength of responding is tested in the absence of nonverbal stimuli. Assessing this repertoire involves the use of contrasting verbal stimuli inserted into intraverbal autoclitic frames. For example, ask a child questions that require conditional intraverbal responding, such as "What can you wear on your feet" along with "What can you wear on your head," "What grows on your head," "What grows in a garden?" and so on.

Verbal Function-altering Effect

Verbal S^Ds can also transform the functional effects of verbal stimuli encountered in the future. The assessment of a child's ability to demonstrate these effects requires the targeted intraverbal to be observed later in time. For example, give the child a verbal instruction such as "When your uncle asks you about your award, tell him you studied hard for it." Then, when the uncle comes in and asks the targeted question, score the child's response. The assessment of this repertoire would involve presenting a variety of these types of verbal instructions and future measures of their effects.

Intraverbal Intervention

Prior to acquiring an intraverbal repertoire, a toddler has already acquired a sizable collection of mands, tacts, and listener skills. An intraverbal repertoire is typically the last of the initial verbal operants acquired (codic skills are acquired later). Some of the first intraverbal relations are simple phrases, songs, fun fill-ins, and common associations. A child's intraverbal repertoire usually expands rapidly between the ages of 2 and 3. This growth corresponds to increases in the complexity of the tact and listener discrimination repertoires, thus providing a child with content to intraverbally talk about. The four types of verbal discrimination (Figure 18.4) and the parts of speech provide organization for early intraverbal training. In addition, the development of intraverbal behaviors by typically developing children can offer a frame of reference for an intraverbal program (Devine et al., 2016; Kisamore et al., 2016; Sundberg, 2014; Sundberg & C. A. Sundberg, 2011).

Simple Verbal Discriminations

Teaching beginning intraverbal behavior to a child involves establishing verbal behavior under the control of simple verbal stimuli. For example, an adult who is playing peek-a-boo may say "peek a . . . " and then implement a brief delay before saying "boo" to evoke the intraverbal response "boo" from the child. Fill-in-the-blank phrases ("You ride a . . . ") are usually easier than WH questions ("What can you ride?") because fill-ins often just involve a simple verbal discrimination, whereas WH questions ultimately involve verbal conditional discriminations. The primary goal at this early intraverbal level is to break the targeted verbal responses free from echoic control, while teaching the child to verbally discriminate among the many verbal stimuli she may encounter. In addition, the fill-in to WH question procedure helps to establish early I-BiN repertoires (Greer & Ross, 2008; Horne & Lowe, 1996).

Compound Verbal Discriminations

Teaching intraverbal behavior controlled by compound verbal stimuli is similar to the procedure previously described for a listener discrimination, except a verbal response is required. For example, the words "brother" and "name" may independently evoke certain behaviors, but when combined to "brother's name" a new stimulus occurs and by prompting, fading, and reinforcing a specific response under these circumstances (e.g., "Cory") compound verbal stimulus control can be established.

Verbal Conditional Discriminations

When considering an intervention program targeting the establishment of VC^Ds, it is important to ensure that the child demonstrates the prerequisite speaker and listener skills (DeSouza et al., 2019; Sundberg & C. A. Sundberg, 2011). For example, prior to being able to intraverbally talk about hot and cold, it is essential that the tact and listener repertoires (e.g., LRFFC) regarding hot and cold are established. If a child can demonstrate these prerequisite skills, and this repertoire has been targeted as a priority, one can turn to a sizable body of research and clinical applications on intraverbal responses controlled by multiple verbal stimuli (for reviews see Aguirre, Valentino, & LeBlanc, 2016; Petursdottir, 2018).

For example, Kisamore et al. (2016) demonstrated the effects of three different procedures for establishing multiply controlled intraverbals with seven participants with autism. The first procedure involved a standard prompt delay and error correction, but this procedure was effective for only three of the participants. Two of the participants benefited from the requirement to echo the question first, termed differential observing response (DOR), and two participants required other modifications of the procedures. Figure 18.7 shows the results for the two participants who failed with prompt delay and error correction, but benefited from the echoic DOR procedure. The data for both participants showed that intraverbal responding during the prompt delay and error correction was variable and did not meet criterion.

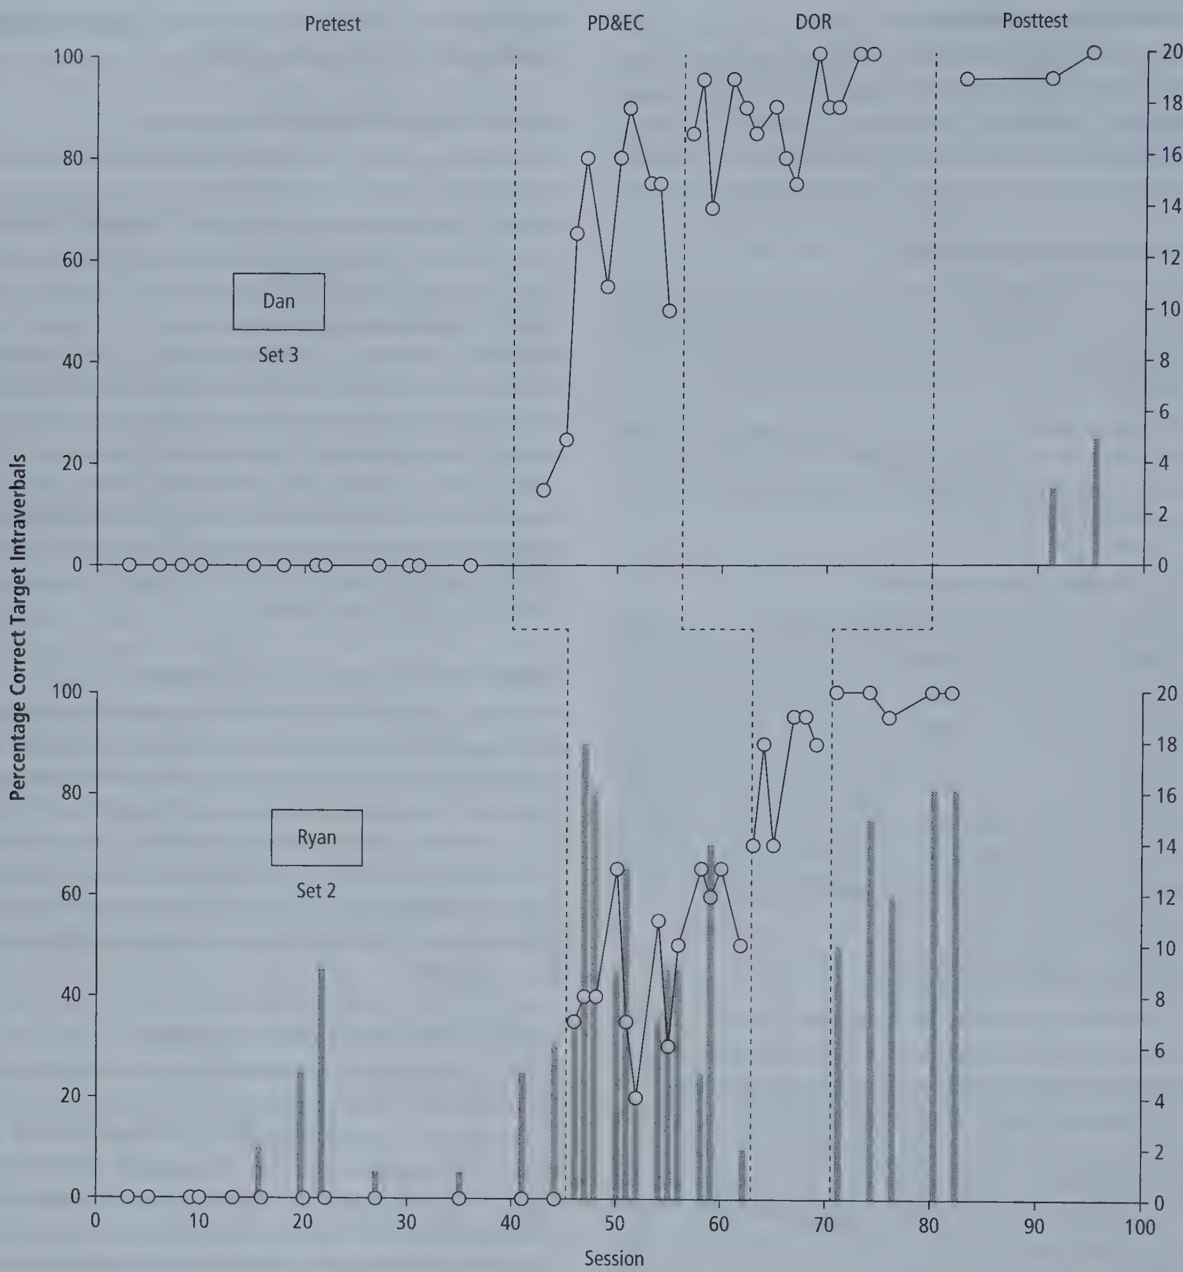

Figure 18.7 Results for the two participants who failed with prompt delay and error correction (PD&EC), but benefited from the differential observing response (DOR) procedure. The open circles show acquired intraverbal responses across conditions, and the bars in the right panel show the number of errors across conditions.

From Teaching Multiply Controlled Intraverbals to Children And Adolescents with Autism Spectrum Disorders" by A. N. Kisamore, A. M. Karsten, & C. C. Mann, © 2016. Reproduce with permission of John Wiley & Sons Inc.,

However, with introduction of the DOR procedure, responding increased to mastery performance.

Verbal Function-altering Effect

The goal in establishing delayed intraverbal behavior is to teach a child how to respond to specific verbal S^Ds that might occur later in time. An instructional program would involve known intraverbal relations and altering the temporal distance between the first and second presentation of the target verbal S^D. For example, if the goal is a future intraverbal interaction in a restaurant, initial conditioning might involve telling a child, "When the waiter asks you, 'What do you want to order?' you tell him chicken nuggets", then engage in role playing involving a second adult and gradually increase the time between each adult's verbal S^D presentation.

Autoclitic Assessment

The following prerequisite skills are necessary to benefit from autoclitic instruction: (1) A speaker's existing verbal skills are sufficient to support secondary verbal behavior,

(2) a speaker demonstrates self-listening skills, and (3) a speaker can tact aspects of her own verbal and nonverbal behavior. Developmental milestones can be helpful for identifying when these types of repertoires emerge (generally around 24 to 36 months of age).

Autoclitic Mands

Secondary autoclitic mands begin to emerge in a speaker's mand repertoire after primary mands have been acquired. For example, does a child put extra stress on certain words, add tags of immediacy, or pause before saying something? If these secondary verbal behaviors are controlled by some MO regarding how a listener should respond to a primary response, along with the relevant history of specific reinforcement, they can be classified as autoclitic mands.

Autoclitic Tacts

The assessment of autoclitic tacts can reveal if a speaker's behavior is controlled by her own verbal behavior and is modified due to its special effects on listeners (e.g., emitting an autoclitic of strength, such as "I KNOW it is mine," or an autoclitic of weakness, such as "I THINK it is mine"). These types of autoclitic tacts begin to demonstrate capabilities with verbal complexities such as self-editing, covert verbal behavior, and verbal self-awareness (Greer & Ross, 2008; Skinner, 1957, 1974). A child's ability to emit tacts controlled by these various types of nonverbal S^Ds can be compared to that of typically developing children for a developmental perspective.

Autoclitic Intervention

Establishing an autoclitic repertoire can be difficult due to the private nature of the relevant controlling variables. In addition, all autoclitic relations involve multiple controlling variables, multiple responses, and a speaker serving as her own listener. Teaching autoclitic mands involves capturing or creating the relevant MOs and using ABA teaching procedures to establish a secondary mand relation. For example, in social interaction with peers a louder voice or a certain phrase may function as an autoclitic mand to prompt a listener to attend better to what the speaker says. Establishing these types of autoclitics can be accomplished with basic ABA procedures, including modeling and role playing.

Teaching an autoclitic tact is complicated by the fact that the target nonverbal S^D must originate from some aspect of the child's own words, and it is that S^D that should evoke the child's autoclitic response. The task for the adult is to bring the child's verbal behavior under the control of some specific aspect of the child's own ongoing verbal behavior. This is not an easy task. For example, a child must first be emitting primary responses in order to generate stimuli to secondarily tact, but a child's own words may be transient, private, multiple, or completely missed by the child. They also may have to compete with other words, ongoing listener behavior, current MOs, and any number of variables that may emerge in verbal exchanges. Two procedures for establishing autoclitic tacts will be described. As with the autoclitic mand, capturing or creating the relevant controlling variables can provide the necessary elements to establish autoclitic tacts.

Capturing Autoclitic Tact Teaching Opportunities in the Natural Environment

Once a repertoire of primary verbal operants is established, autoclitic tacts can emerge in typically developing children without formal instruction. This is because listeners, often unintentionally, provide differential reinforcement for autoclitic behavior. Listeners also prompt speakers for autoclitic expansions of their primary response (e.g., "Where did you hear that?"). Certain settings and activities may be more conducive to evoking primary verbal behavior, such as play activities, arts and crafts, or outdoor events and games. Often, autoclitic behavior is already occurring in the context of ongoing verbal behavior, and if an adult can identify its presence, the adult can provide reinforcement for that behavior. For example, upon observing a wave in a water pool, a child emits the response, "That was SO big"—a response that appears to contain a descriptive autoclitic. An adult can reinforce the additional autoclitic behavior by drawing attention to the "SO" part (e.g., "Wow that was the biggest one!").

Formal Arrangement of Autoclitic Tact Contingencies

If a child demonstrates the prerequisite skills identified above, she may be prepared to learn to emit autoclitic behavior through direct teaching procedures (e.g., multiple exemplar instruction). For example, if the targeted autoclitic relation involves a child informing the listener of the sense mode that is affecting her primary tact, she must first learn to discriminate between seeing things, hearing things, smelling things, and so on. A formal teaching procedure could begin with a primary response evoked with a standard tact trial to set up the necessary conditions for tacting the nonverbal source of control for that response (e.g., visual or auditory). When the stimulus is visual, the echoic prompt "I see the ball" can be used to prompt a response (at this point "I see" is not autoclitic; it is a primary echoic operant). When the stimulus is auditory (e.g., the sound of a ball bouncing), the echoic prompt "I hear the ball" can be provided. Both types of echoic prompts need to be faded, trials presented randomly, and stimulus control transferred to the type of sensory antecedent that controls the primary tact "ball." It is important to transfer what is acquired through direct instruction to natural environment contingencies where sensory information is valuable to the listener (e.g., hide-and-seek games, emergency situations). Similar procedures could be conducted for the many other types of descriptive autoclitics, as well as for quantifying and relational autoclitics.

Autoclitics are an important aspect of a verbal repertoire, but the private nature of the controlling contingencies make them difficult to study. Fortunately, a growing body of autoclitic research is available (e.g., Hübner, Austin, & Miguel, 2008; Lowenkron, 1998, 2006; Luke et al., 2011; Palmer, 2011; Sidener & Michael, 2006; Speckman et al., 2012; C. T. Sundberg et al., 2018).

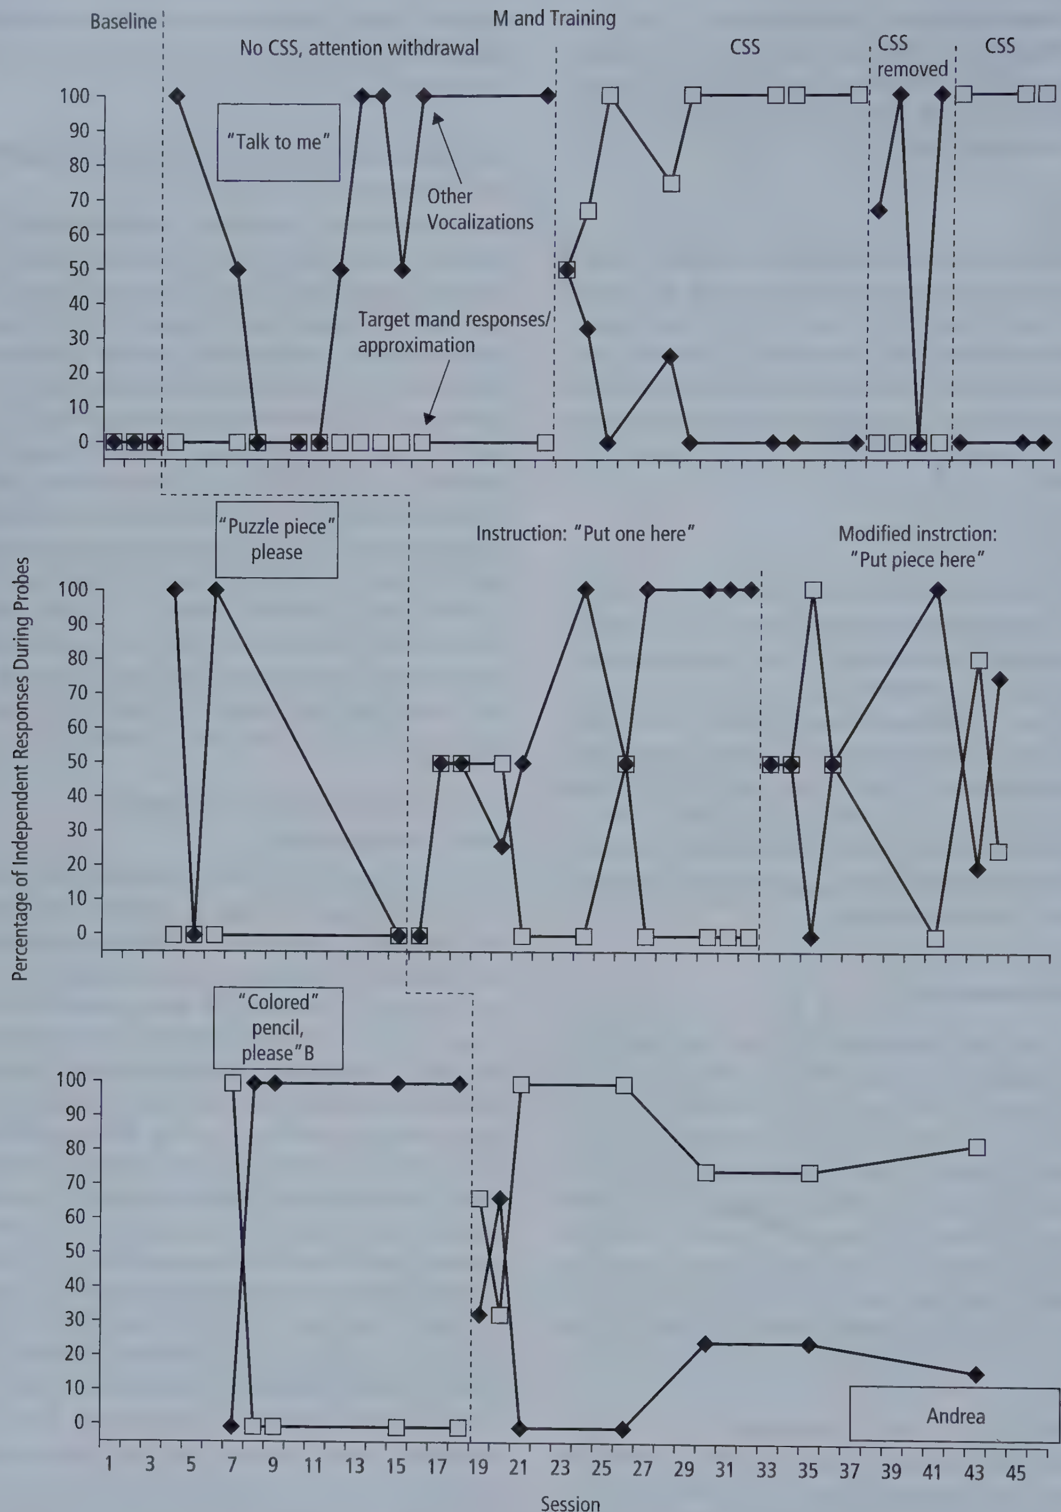

Figure 18.8 The results for Andrea show her absent or weak mands during baseline; the open squares represent the specific target words (e.g., "colored pencil"), and the closed diamonds represent indirect vocal words as mands (e.g., "I don't know what to do," "OK"). The first condition was ineffective in evoking the target mand, but the second condition involving various types of verbal prompts such as a contingency specifying stimulus (CSS), produced successful manding and reduced inappropriate mands.

THE LOSS OF VERBAL BEHAVIOR

Skinner's analysis of VB can serve as a guide for language assessment and intervention for an individual experiencing a verbal loss, much in the same way it does for initial language acquisition. Verbal repertoires can weaken significantly, as observed in cases of dementia, Alzheimer's disease, aphasia, and traumatic brain injury (Baker, LeBlanc, & Raetz, 2008; Gross, Fuqua, & Merritt, 2013; Palmer, 1991; Sundberg, 2016b; Sundberg, San Juan, Dawdy, & Arguelles, 1990; Trahan, Donaldson, McNabney, & Kahng, 2014). An adult with dementia may, for example, experience memory loss, engage in off-topic verbalizations, or neglect important aspects of daily living (e.g., Bourgeois, 1993; LeBlanc, Raetz, & Feliciano, 2011).

In his discussion of aphasia and the loss of verbal behavior, Skinner (1957) points out the following: "The order of damage seems to follow the order of 'difficulty' deducible from the availability of a minimal repertoire. Textual and echoic behavior often survive (unless relevant sensory defects are involved) while intraverbals and tacts appear to be most vulnerable" (p. 219). Identifying the strength of each verbal operant and the functional sources of control for an adult's impaired verbal behavior can provide direction for an intervention program. For example, data regarding the nature of a person's loss can be obtained by assessing intraverbal repertoires regarding recent and past events, mands for information, tacting complex stimuli, and the occurrences of odd or irrelevant VB (e.g., Gross et al., 2013; Sundberg, 2014).

The body of research on applying Skinner's analysis of verbal behavior to problems related to the loss of language is expanding (e.g., Dixon, Baker, & Sadowski, 2011; LeBlanc et al., 2011; Oleson & Baker, 2014). For example, Oleson & Baker (2014) examined manding problems experienced by older adults with dementia. These authors suggested that "[t]raining mands could not only lead to an improved quality of life by providing individuals with dementia the ability to access desired items and activities . . . but may also reduce aggression and other challenging behavior" (p. 115). In Oleson and Baker's (2014) study, two participants with dementia experienced a mand training condition consisting of contriving an MO (e.g., providing paper and no colored pencils), verbal prompts, fading, specific reinforcement, and error correction. The results revealed that the procedure was effective with one participant, but results were inconsistent with the second participant. Figure 18.8 shows the results for the successful participant, Andrea, who acquired two mands and partially acquired a third. In the mand baseline condition, Andrea emitted indirect vocal words as mands (e.g., "I don't know what to do," "OK"), as indicated by the closed triangles, but rarely emitted the specific target words (e.g., "colored pencil"), as indicated by the open squares. The first condition consisted of contriving the EO alone, which was ineffective in evoking the target mand. However, the second condition involving the contrived MO plus an indirect supplemental verbal prompt resulted in successful manding and reduced inappropriate mands. These data are similar to the results reported for Jason in the opening vignette, where Jason's inappropriate mand was replaced by an acceptable response form through a basic mand training procedure. Many other teaching procedures have proven effective for children with autism or other intellectual disabilities that can be modified and used for individuals experiencing a loss of verbal behavior.

SUMMARY

Skinner's (1957) Analysis of Verbal Behavior

1. Skinner argues that language constitutes learned speaker and listener behavior that is acquired, maintained, and extended by environmental contingencies of reinforcement.
2. A given utterance is comprised of formal properties (the words spoken) and functional properties (why those words were spoken).
3. The formal properties of language involve the topography and structure of verbal responses usually classified in terms of the parts of speech, clauses, and sentences.
4. The functional properties of language involve the causes of a response often referred to as semantics, or the meaning of words.
5. From a behavioral perspective, the meaning of a word can be found in the immediate and historical antecedents and consequence that evoke that word.
6. By treating language as learned behavior emitted by speakers and listeners, the focus of the analysis and its applications is on the contingencies responsible for that behavior.
7. Skinner (1957) defined verbal behavior "as behavior reinforced through the mediation of other persons" (p. 2), but those other persons "must be responding in ways which have been conditioned *precisely in order to reinforce the behavior of the speaker*" (p. 225).
8. Language involves an interaction between a speaker and a listener, including when a speaker is her own listener. Skinner terms the basic unit of analysis for this interaction a *verbal episode*.
9. In a verbal episode, a speaker emits any type of verbal behavior (e.g., mand, tact, intraverbal), in any form (e.g., speech, sign language, eye contact).
10. In a verbal episode, a listener (1) serves as an audience for a speaker, (2) provides reinforcement for a speaker, and (3) responds in specific ways to the speaker's behavior.

11. The roles of speaker and listener alternate in verbal episodes, and usually involve covert speaker and listener behavior as well.

12. Verbal behavior is not restricted to spoken words. Any form of operant behavior can acquire a verbal function (e.g., sign language, fingerspelling, icon selection, Braille, facial expressions, intonation).

13. In topography-based verbal behavior, each verbal relation involves a distinguishable response form given some specific controlling variable.

14. In selection-based verbal behavior, the response form is the same for each verbal relation (e.g., pointing, selecting); what is conveyed to the listener is the stimulus indicated.

15. A behavioral cusp is a form of generative learning in which the acquisition of one skill or specific set of skills enables the acquisition of other skills without direct teaching or a history of reinforcement. A cusp can allow access to new MOs, stimuli, reinforcers, and punishers, which in turn generate new behavior.

16. The basic components of a speaker's verbal repertoire are called the elementary verbal operants (e.g., mand, tact, intraverbal).

17. The mand is a verbal operant in which the form of the response is under the functional control of motivating operations (MOs) and a history of specific reinforcement.

18. The tact is a verbal operant in which the form of the response is under the functional control of a nonverbal S^D and a history of generalized S^r.

19. There are three types of dupic relations: echoic, motor imitation, and copying text, and two types of codic relations: textual and taking dictation.

20. The echoic (duplic) is a verbal operant in which the form of the response is under the functional control of a verbal S^D that has formal similarity with a verbal response and a history of generalized S^r.

21. Formal similarity occurs when the controlling antecedent stimulus and the response product (a) share the same sense mode (i.e., both stimulus and response are visual, auditory, or tactile) and (b) physically resemble each other.

22. The intraverbal is a verbal operant in which the form of the response is under the functional control of a verbal S^D that does *not* have point-to-point correspondence to the verbal response, but does have a history of generalized S^r.

23. Point-to-point correspondence between the stimulus and the response or response product occurs when the beginning, middle, and end of a verbal stimulus matches the beginning, middle, and end of a verbal response.

24. The textual relation (codic) is a verbal operant in which the form of the response is under the functional control of a written verbal S^D that does not have formal similarity, but does have point-to-point correspondence and a history of generalized S^r.

25. Taking dictation (codic) is a verbal operant in which the form of the response is under the functional control of a verbal S^D that controls a written, typed, Braille punched, or Fingerspelled response. Like the textual relation, there is no formal similarity, but there is point-to-point correspondence and a history of generalized S^r.

26. Listener discriminations (commonly referred to as receptive language) can be defined as a verbal S^D that evokes a corresponding nonverbal response (or class of responses) due to a history of generalized S^r.

27. The generalized ability to match nonverbal sample stimuli to nonverbal comparison stimuli can facilitate the establishment of equivalent and nonequivalent relations.

28. Classifying verbal relations allows us to more precisely identify, organize, and account for the specific variables that might be responsible for a given utterance.

The Verbal Operants and Listener Behavior in more Detail

29. Mands can be classified by identifying the different types of MOs that control manding behavior (e.g., UMOs, CMOs), and by the different ways mands affect the behavior of the listener and produce specific reinforcement.

30. The defining consequences for the mand constitute what Skinner identifies as specific reinforcement. Specific reinforcement involves reinforcement that is established by its relation to a specific MO (e.g., water deprivation establishes water as specific reinforcement).

31. Several types of MOs are related to aversive stimulation (e.g., too hot, loud noises, demands), and their removal functions as specific negative reinforcement.

32. When sufficient specific positive or negative reinforcement has been provided, it abolishes the MO (e.g., satiation).

33. Any instance of human behavior is usually a function of multiple variables operating simultaneously. There are two types of multiple control: convergent multiple control and divergent multiple control.

34. In convergent multiple control, a single response is controlled by more than one antecedent variable.

35. In divergent multiple control, a single antecedent variable controls more than one response.

36. It is common to have multiple MOs and S^Ds operating simultaneously within a single verbal episode.

37. The involvement of multiple antecedent variables can enhance or weaken an evocative effect.

38. A private event is only felt by one person. However, private events can have immediate behavioral effects (e.g., MOs, covert verbal S^Ds), and should be taken into account for a complete interpretation of behavior.

39. Public accompaniment occurs when a publicly observable stimulus reliably occurs with a private stimulus.

40. Collateral responses are publicly observable behaviors that reliably occur with a private stimulus.

41. Once a child has acquired basic echoic, mand, tact, and listener repertoires, the combination of these cusps can produce emergent mands and generative learning in a number of different ways (e.g., tact to mand transfer, incidental mand acquisition).

42. Classifying tacts can be accomplished by identifying the different types of nonverbal S^Ds that control responses, and by the different ways these verbal responses affect the behavior of the listener.

43. Nonverbal S^Ds commonly participate in verbal episodes with other types of antecedent variables (e.g., CMO-Ts, verbal S^Ds).

44. Once a tact relation has been established, the tact response can extend to novel stimulus conditions through the process of stimulus generalization.

45. In generic tact extension, the novel stimulus shares all of the relevant or defining features associated with the original stimulus.

46. In metaphorical tact extension, the novel stimulus shares some, but not all, of the relevant features of the original stimulus.

47. In metonymical tact extension, the novel stimulus shares none of the relevant features of the original stimulus configuration, but some irrelevant but related feature has acquired stimulus control.

48. In solecistic tact extension, a stimulus property has no clear connection to the original stimulus, but the novel stimulus has acquired control through some type of reinforcement history.

49. Listeners provide five different types of generalized S^r for tacting: (1) educational reinforcement, (2) escape from or avoidance of aversive stimulation, (3) extending the listener's contact with the environment, (4) automatic reinforcement, and (5) a history of contiguous or correlated usage.

50. Skinner (1957) used the term "automatic" to identify circumstances in which behavior is evoked, shaped, maintained, strengthened, or weakened by environmental variables occurring without direct manipulation by other people.

51. Automatic reinforcement can occur when the reinforcement is provided by the response product emanating from the behavior.

52. Automatic reinforcement can occur when the reinforcement is provided by the behavior's reinforcing effects emanating from the physical environment.

53. Generative verbal learning is a behavioral effect where previously acquired speaker and listener skills enable or accelerate the acquisition of other speaker and listener skills, without dependence on direct teaching or a history of reinforcement.

54. Once a child has acquired basic echoic, tact, listener, and matching-to-sample repertoires, the combination of these cusps can produce emergent tacts in a number of different ways (e.g., stimulus equivalence, recombinative generalization, common bidirectional naming, joint control, and relational framing).

55. Stimulus equivalence occurs when, for example, the direct teaching of an AB relation between a word (stimulus A) and an object (stimulus B), and the direct teaching of a BC relation between the same object (stimulus B) and a different stimulus (stimulus C), can generate several untrained speaker and listener relations (BA/CB symmetry and AC/CA transitivity). When emergence occurs with both symmetry and transitivity, equivalence has occurred (Chapter 19).

56. Recombinative generalization is a type of multiple control involving learning to respond to novel combinations of antecedent variables as both a speaker and a listener.

57. Bidirectional naming (BiN) is a higher order verbal cusp consisting of the fusing of the speaker and listener repertoires in bidirectional relations. In common BiN, a new word acquired as listener can generate a tact relation without further training, and a new word acquired as a tact can generate a listener relation without further training.

58. Joint control involves the combination of verbal skills (e.g., echoic and tact) and occurs when two separately established antecedents that evoke the same response topography arise simultaneously and produce an emergent S^D that evokes behavior.

59. Relational framing involves an extension of Sidman's equivalence theory to nonequivalent stimulus relations such as comparison, opposition, and difference (Chapter 20).

60. Verbal S^Ds have the same causal status as nonverbal S^Ds in that both types of S^Ds acquire discriminative control over behavior through a history of differential reinforcement.

61. Six types of elementary verbal operants are controlled by verbal S^Ds: echoic, motor imitation (relating to sign language), copying text, textual, taking dictation, and intraverbal. All of these relations are duplic or codic, except for the intraverbal.

62. Intraverbal relations can be classified by identifying the type of verbal stimulus control that evokes the intraverbal response.

63. The intraverbal response can be controlled by four different types of verbal stimulus control: (1) simple verbal discriminations, (2) compound verbal discriminations, (3) verbal conditional discriminations, and (4) verbal functional-altering discriminations.

64. A simple verbal discrimination involves a single-component word or phrase that evokes an intraverbal response.

65. A compound verbal discrimination involves two or more verbal S^Ds (convergent multiple control) that each

independently evoke behavior, but when they both occur in the same antecedent configuration, a different S^D is generated, and a more specific intraverbal response is evoked.

66. A verbal conditional discrimination is a type of convergent multiple control involving a verbal stimulus that alters the evocative effects of another verbal stimulus in the same antecedent configuration, and evokes a corresponding intraverbal response.

67. The verbal function-altering effect occurs when verbal stimuli condition the behavior of a listener by changing the functions of other stimuli and MOs that the listener encounters immediately or later in time (e.g., instructions).

68. Generalized S^r provided by listeners (e.g., praise, approval) establishes verbal stimulus control over verbal behavior, in the same way it does for nonverbal stimulus control.

69. Research has demonstrated that intraverbal relations can emerge from previously acquired tact, intraverbal, and listener repertoires, and even from direct observation. Intraverbal behavior can also emerge through the process of bidirectional naming.

70. Intraverbal bidirectional naming (I-BiN) involves a bidirectional relation that is established between at least two verbal stimuli (e.g., "cat" & "animal"). I-BiN occurs when AB training on a unidirectional intraverbal relation automatically produces a reverse BA intraverbal relation, and vice versa.

Listener Behavior

71. A listener is an active participant in verbal exchanges and serves many roles in this capacity, such as acting as an audience, providing reinforcement for speakers, and taking action upon a speaker's words.

72. The same four types of verbal discriminations described for intraverbal relations can be used as a framework to identify various types of nonverbal listener discriminations. In addition, there is a fifth type of verbal discrimination that is specific to listener behavior commonly termed an auditory conditional discrimination.

73. In an auditory conditional discrimination, a verbal stimulus alters the evocative effect of a nonverbal stimulus due to a history of reinforcement and evokes a corresponding nonverbal response.

74. A listener often engages in overt or covert verbal behavior in the process of listening to a speaker; when this occurs the listener is now a speaker, and his behavior should be classified as such.

75. A speaker can also be her own listener. We can, and often do, talk to ourselves.

Autoclitic Verbal Behavior

76. A speaker often adds autoclitic responses to her on-going primary verbal behavior because autoclitic responses provide a listener with more information about a speaker's primary response, and a listener reinforces a speaker for this extra information.

77. A primary verbal response constitutes any of the verbal operants (e.g., mand, tact, intraverbal).

78. A secondary autoclitic response is controlled by some aspect of the primary verbal operant or by its controlling variables. There are three types of secondary autoclitic behavior: autoclitic mand, autoclitic tact, and autoclitic intraverbal frames.

79. The autoclitic mand enjoins a listener to take some specific action regarding the primary response, and the autoclitic behavior is reinforced by that action.

80. The autoclitic tact is controlled by some nonverbal feature of the primary response or its controlling variables, and the autoclitic response informs the listener of that feature. This behavior is reinforced by listeners who provide generalized S^r.

81. Intraverbal autoclitic frames provide order, agreement, grouping, and composition of larger units of verbal behavior. An autoclitic frame facilitates the connections between words in a given utterance and is reinforced by listeners who provide generalized S^r.

Applications of Skinner's (1957) Analysis of Verbal Behavior

82. Behavior analysis provides three major contributions to language assessment and intervention programs for individuals with special needs: (1) applied behavior analysis technology, (2) a behavioral analysis of human development, and (3) a behavioral analysis of language.

83. Applied behavior analysis can provide professionals and parents with the necessary intervention procedures and scientific methods to teach language skills.

84. The development of language and social skills by typically developing children can provide a valuable guide for a language intervention curriculum.

85. Skinner's analysis of verbal behavior can serve as a framework for specific language assessment and intervention programs.

86. A language assessment for a person with language delays has three primary goals: (1) to identify the nature of the delay or problem, (2) to compare the person's performance with expected norms, and (3) to provide guidance for an appropriate intervention program if necessary.

87. Language assessment for a person with language delays involves measuring the strength of the elementary verbal operants, listener skills, self-listener skills, multiply controlled responding, speaker-listener interactions.

88. Assessing a child's mand repertoire involves identifying the degree to which the various MOs control verbal responses.

89. There are two general methods are used for identifying and controlling the value change of MOs for mand training: (1) capturing the MO value change as it occurs naturally and (2) creating the MO by generating some change that alters the value of a consequence.

90. Assessing a tact repertoire involves determining the degree to which nonverbal stimuli control verbal behavior.

91. The goal of a tact intervention program is to establish a fluent and generative tact repertoire that is functional for the child, and integrated with the other speaker and listener repertoires.

92. A listener assessment can be framed by the parts of speech and the five types of verbal discriminations previously described. In addition, an assessment of a child's self-listener skills is important.

93. Early listener discrimination skills should be established simultaneously with early tacting skills.

94. Learning to be a listener involves the capability to discriminate between words (or signs, text, etc.), especially when they appear in novel combinations, in different nonverbal environments, and under different MOs.

95. The four types of verbal discriminations, along with the parts of speech, and multiple control involving nonverbal S^Ds and MOs, can provide a framework for intraverbal assessment and intervention.

96. The development of intraverbal behaviors by typically developing children can offer a frame of reference for an intraverbal intervention program.

97. There are several prerequisite skills are necessary to benefit from a formal autoclitic intervention program: (1) A speaker's existing verbal skills are sufficient to support secondary verbal behavior, (2) a speaker demonstrates self-listening skills, and (3) a speaker can tact aspects of her own verbal and nonverbal behavior.

98. Generative verbal learning is a major goal for a language intervention program. Procedures from stimulus equivalence, relational framing, bidirectional naming, and joint control can all help to facilitate the emergence of generative repertoires for a person with language delays.

The Loss of Verbal Behavior

99. Verbal repertoires can also deteriorate, as observed in cases of dementia, Alzheimer's disease, aphasia, and traumatic brain injury. Skinner's analysis of VB can serve as a guide for language assessment and intervention for these individuals much in the same way it does for those learning to communicate for the first time.

KEY TERMS

audience
autoclitic
automatic punishment
automatic reinforcement
convergent multiple control
copying a text
divergent multiple control
echoic
formal similarity
generic (tact) extension
impure tact
intraverbal
listener
mand
metaphorical (tact) extension
metonymical (tact) extension
multiple control
point-to-point correspondence
private events
solistic (tact) extension
speaker
tact
textual
taking dictation
verbal behavior
verbal operant

MULTIPLE-CHOICE QUESTIONS

1. The formal properties of language involve the:
   a. Cause of the verbal response
   b. Topography of the verbal response
   c. Unseen forces of verbal language
   d. Language properties are not formal
   Hint: (See "Form and Function of Language")

2. The functional properties of language involve:
   a. Causes of the verbal response
   b. Topography of the verbal response
   c. Language properties do not have functional components.
   d. Unobservable psychic antecedents.
   Hint: (See "Form and Function of Language")

3. A mand is a type of verbal operant in which a speaker:
   a. Differentially responds to the verbal behavior of others
   b. Asks for (or states, demands, implies, etc.) what he or she needs or wants
   c. Repeats the verbal behavior of another speaker
   d. Names things and actions that the speaker has direct contact with through any of the sense modes

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

4. An intraverbal response is a type of verbal operant in which a speaker:
   a. Differentially responds to the verbal behavior of others
   b. Asks for (or states, demands, implies, etc.) what he needs or wants
   c. Repeats the verbal behavior of another speaker
   d. Names things and actions that the speaker has direct contact with through any of the sense modes

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

5. A tact is a type of verbal operant in which a speaker:
   a. Differentially responds to the verbal behavior of others
   b. Asks for (or states, demands, implies, etc.) what he needs or wants
   c. Repeats the verbal behavior of another speaker
   d. Names things and actions that the speaker has direct contact with through any of the sense modes

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

6. A textual operant has
   a. Point-to-point correspondence but no formal similarity
   b. Point-to-point correspondence and formal similarity
   c. No point-to-point correspondence and no formal similarity
   d. None of these

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

7. Taking dictation consists of:
   a. A discriminative stimulus evoked by a verbal response that does not have point-to-point correspondence.
   b. Reading without any implications so that the reader understands what is being read
   c. Writing and spelling words that are spoken
   d. None of these

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

ESSAY-TYPE QUESTIONS

1. Explain some of the factors in the slow appreciation of Verbal Behavior.

   Hint: (See "Form and Function of Language")

2. Describe the term mand. Be sure to include in your answer the definition of the term and its importance for the early development of language.

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

3. Describe the term tact.

   Hint: (See "The Elementary Verbal Operants and Listener Discriminations")

4. Compare and contrast convergent multiple control and divergent multiple control.

   Hint: (See "Multiple Control")

NOTES

1. For ease of reading throughout the chapter, the male pronoun will be used for the listener and the female pronoun will be used for the speaker.
2. However, when using the term *verbal behavior* to refer to Skinner's analysis of language, the "verbal" part involves the behavior of the speaker, but where is the behavior of the listener in that term? Skinner did not neglect the listener in the analysis, but one must add the phrase "and the behavior of the listener" when describing Skinner's analysis of verbal behavior. An alternative is to use the phrasing "speakers and listeners" when describing the complete verbal field.
3. For more detail, see Carbone (2013); Endicott and Higbee (2005); Hall and Sundberg (1987); Landa, Hansen, and Shillingsburg (2017); Lechago, Carr, Grow, Love, and Almason (2010); Oleson and Baker (2014); and Sundberg, Loeb, Hale, and Eigenheer (2002).
4. For reviews and research topics, see Aguirre, Valentino, and LeBlanc (2016); Dymond, O'Hora, Whelan, and O'Donovan (2006); Gamba, Goyos, and Petursdottir (2015); Petursdottir (2018); Petursdottir and Devine (2017); Sautter and LeBlanc (2006); Sundberg (2013).
5. See Sundberg and C. A. Sundberg (2011) for a developmentally sequenced 80-item intraverbal subtest for the *Verbal Behavior Milestones Assessment and Placement Program (VB-MAPP)* (Sundberg, 2014).

PART 8

Developing New Behavior

The five chapters in Part 8 describe methods for developing new behavioral repertoires. Chapter 19, by Carol Pilgrim, outlines the research foundations and core concepts for equivalence-based instruction (EBI) and discusses several key outcomes of EBI, namely, class formation, delayed emergence, class expansion and class merger, transfer of function, and contextual control. The chapter ends with a treatment of how to apply EBI in instructional and generalized settings, as well as applications viewed through the perspectives of Naming Theory and Relational Frame Theory.

Chapter 20, by Tom Critchfield and Ruth Anne Rehfeldt, describes how learning can be engineered with nonequivalent relations. After defining nonequivalence classes and why they matter, these authors present the basic vocabulary for explaining nonequivalence relations, describe types and examples of nonequivalence relations, review key theoretical concepts, address the role of nonequivalence relations in higher-order psychological constructs, and explain how nonequivalence relations provide a basis for enhancing well-being in ways that are quite different from typical approaches in applied behavior analysis.

Chapter 21 details how new behaviors are acquired through modeling, imitation, and observational learning. After defining and providing examples of these terms, and outlining a training protocol for learners who do not display imitative behavior, the chapter describes how practitioners can use modeling as a behavior change strategy and teach children to be skilled observational learners.

Chapter 22 describes how to shape new behavior by reinforcing successive approximations to a terminal behavior. The chapter also includes procedures for increasing the efficiency of shaping and guidelines for using shaping in applied settings.

Chapter 23 explains how discrete responses can be linked to create behavior chains of more complex behaviors. Procedures for task analysis—breaking down complex tasks into sequenced steps for instruction—are described. The chapter addresses the varied methods of chaining and factors affecting the performance of behavior chains.

CHAPTER 19

Equivalence-based Instruction

Carol Pilgrim

LEARNING OBJECTIVES

- Understand the research foundations and core concepts of equivalence-based instructions.
- Learn the designing of equivalence-based instructions procedures.
- Discuss the application and generality of equivalence-based instructions with varied participant populations.
- Discuss the applications stemming from alternative theoretical approaches to relational responding.

It would be difficult to overestimate the role played by symbols in our everyday lives. Consider my commute to work this morning: As I left the house, I discovered a small vase on my vanity, filled by my better half with fresh azaleas from our garden. With considerable goodwill toward the world, then, I pushed the button marked "Start" on my car's dash, moved the shifter to "R," and punched "5" on the console for our local NPR station. An angry debate was in progress on the meaning of "building the wall" for U.S. Democrats and Republicans, for American immigrants (past, present, and future), and, indeed, for observers from around the world. With a quick shift to my shuffled music play list, John Lennon's "Give Peace a Chance" created a powerful contrast. Shortly thereafter, a swing by the drive-through of my local bank branch allowed me to deposit a check and move funds from one account to another, with nary a coin exchanged. Next, while crossing campus, I negotiated traffic lights, traffic signs, and hand signals from Officer O'Malley. Graduating seniors in regalia, having just received their caps and gowns, were posing in front of every Seahawk sculpture on the university grounds, hamming it up for selfies with friends. As I parked and approached my office, the chime of the clock tower quickened my pace to a meeting with one of my graduate students, to review her thesis progress.

This short vignette relates a sequence of ordinary events—ones that flow so automatically they'd be unlikely to receive a second thought, all seemingly unremarkable. On closer inspection, however, an observant reader might note that every detail of this anecdote involves a symbol. Ranging from the mundane to the sublime (e.g., from braking to love), these symbols were responsible for my very ability to have an ordinary morning. Indeed, much of the richness of our lives, both the precision (e.g., account balances) and the breadth (e.g., abstractions like peace) of our experience, is made possible by the symbolic function of the events that surround us. Imagine the limitations that would necessarily characterize the world of individuals for whom symbolic function is not so easily acquired and, conversely, the benefits that accrue when multiple symbolic functions are generated rapidly. What sorts of steps might be taken to establish symbols when they are lacking, or to maximize their number efficiently? How can a single symbol come to hold a range of different meanings across individuals (e.g., from security to oppression)? And while we may feel that "we know one when we see one," what, exactly, do we mean when we speak of a symbol anyway? The few examples given here should help to illustrate that if we are ever to achieve a healthy and happy world, or even a minimally functional one, it will be important to find answers to such questions. In point of fact, these are the questions that lie at the heart of the study of stimulus equivalence.

Behavior analytic research on stimulus equivalence explores how a person's experience with the environment establishes or changes the function of symbols—that is, their ability to impact our behavior, or their meaning. In doing so, this research helps us understand a great deal about human behavior and about how instruction can be designed and delivered to maximize learning outcomes. Indeed, one of the most significant characteristics of equivalence-based instruction (or EBI) is its generativity. When designed properly, a small amount of explicit instruction can yield an extensive and predictable network of new relations that were not directly targeted by the teaching, which is certainly a win-win scenario for student and teacher alike. The tremendous "bang for the buck" nature of EBI makes it especially relevant to today's pressing need for efficient and effective educational strategies. This chapter further develops the basic concept of stimulus equivalence by illustrating a wide range of equivalence outcomes in applied research

and by outlining key features of the equivalence procedures that practitioners or teachers can incorporate into their own instruction efforts.

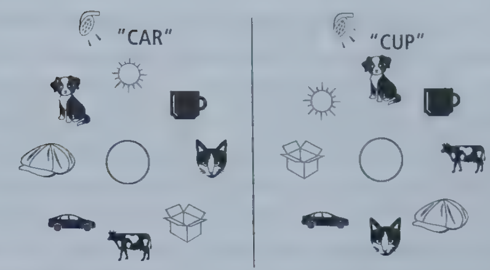

Figure 19.1 An illustration of two trials of the AB matching-to-sample procedure, with the spoken sample stimulus indicated at the top of each diagram.

From "Equivalence Relations and Behavior: An Introductory Tutorial," by M. Sidman, 2009, *The Analysis of Verbal Behavior*, *25*, p. 8. Used by permission.

RESEARCH FOUNDATIONS AND CORE CONCEPTS

The behavior analytic approach to symbolic function known as **stimulus equivalence** made its debut in the early 1970s (Sidman, 1971; Sidman & Cresson, 1973) and received its first full operational treatment in 1982 (Sidman & Tailby, 1982; Sidman et al., 1982). That's not so very long ago in science years. Since that time, probably no other single topic has occupied more attention across the domains of basic experimental, conceptual, and applied behavior analytic science. Let's begin with a brief review of the equivalence phenomenon, before turning our attention to the reasons for its emphasis within the field.

Pioneering Research on Symbolic Stimulus Relations

What Was Taught

Sidman's initial studies on reading acquisition (Sidman, 1971; Sidman & Cresson, 1973) provide a perfect context for an introduction to the basic terms and concepts of an equivalence approach. Because these terms and concepts will play a critical role in the descriptions to follow throughout this chapter, we will spend some time here developing each of them with respect to Sidman's landmark studies. The participants in these experiments were three institutionalized young men (ages 17 to 19) with severe intellectual disabilities. Despite extensive teaching histories, none of the participants had developed any reading skills whatsoever. Sidman targeted this critical functional repertoire with a teaching arrangement known as the **matching-to-sample procedure**, an arrangement that has much in common with everyday classroom teaching approaches. Matching-to-sample is a *discrete-trial procedure*; in Sidman's case, each teaching trial began with the repeated presentation of 1 of 20 different spoken words, referred to as *sample stimuli*, and the illumination of a round key in the center of the teaching apparatus. The participant was required to touch the illuminated key, to indicate that the spoken word had been noticed, a response referred to as an *observing response*. The observing response resulted in presentation of eight simple line drawings, known as *comparison stimuli*, arranged in a circular configuration around the sample key. One of the comparison drawings corresponded to the spoken word presented as the sample stimulus on that trial; for example, given the spoken word "car" as the sample, the comparisons might include drawings of a car, a sun, a cup, a cat, a box, a cow, a cap, and a dog. (See Figure 19.1 for an illustration of two trial presentations.) The participant's job at this point was to select one of the comparison stimuli, again by touching it. Selecting the drawing that corresponded to the spoken word (e.g., selecting the picture of a car after hearing "car") produced pennies and a chime; that is, the corresponding comparison was *discriminative* for reinforcement. Selecting any of the nonmatching comparison stimuli had no programmed consequences. In either case, a brief interval followed, after which the next trial began.

Across trials, each of the 20 words was presented as a sample stimulus. Thus, the comparison stimulus designated as correct, or discriminative, on any given trial varied as a function of the specific sample stimulus presented on that trial. After hearing "car," selecting the picture of a car produced reinforcers; after hearing "cup," selecting the picture of a cup produced reinforcers; and so on. The participant could not earn reinforcers consistently by selecting the correct comparison from the previous trial; correct selections had to "match the sample." Said a bit more technically, stimulus control by the sample stimulus determined the discriminative comparison stimulus. The matching-to-sample procedure thus arranges a *four-term contingency*, the positive elements of which include two antecedent stimuli (the sample stimulus and the correct comparison stimulus), the selection response, and the reinforcer. The four-term contingency brings the more familiar three-term contingency under another level of antecedent stimulus control in that the sample stimulus determines the appropriate three-term, or discriminative, unit. The performance produced by this four-term contingency (i.e., selecting the appropriate comparison on each trial) is known as **conditional discrimination** because discrimination between the comparison stimuli is conditional upon, or depends upon, the sample stimulus present on each trial. It follows that the sample stimuli are also known as *conditional stimuli* in this arrangement. In Sidman's first training phase, then, the discriminative function of each picture was conditional on the word spoken. Also with respect to terminology, Sidman's teaching arrangement could be described as an *arbitrary* or sometimes even a *symbolic* matching-to-sample procedure, because the correct comparison stimulus on a given trial did not depend on any physical relation to the sample (as opposed to *identity matching-to-sample*, where the sample and correct comparison are physically identical, or *oddity matching-to-sample*, in which the correct comparison is the only one physically different from the sample).

It is common in the literature on equivalence to find alphanumeric labels used to specify individual training stimuli. This practice is useful in providing a standard descriptive system that readily accommodates the many variations in stimulus types and

training procedures that are represented in the literature. It can take a little getting used to, but gaining some familiarity with this system will facilitate descriptions of the studies presented throughout the remainder of this chapter and make them easier to follow as a reader. Each alphanumeric label designates a physically unique stimulus, where the letter denotes a stimulus set (e.g., a set of sample stimuli, or a set of comparisons) and the number denotes a potential equivalence class. For example, the spoken-word sample stimuli in Sidman's reading studies could be designated as A1, A2, A3, . . . A20; and across training trials, each sample would be presented along with an array of eight drawings from the B stimulus set, designated as B1, B2, B3 . . . B20. As reviewed previously, during training, selecting comparison B1 in the presence of sample A1, selecting B2 in the presence of A2, and so on, would produce a consequence determined to serve as a reinforcer, while selecting any of the alternative comparisons would result in the intertrial interval only. Once selection of the appropriate B comparison stimulus is demonstrated reliably in the presence of each A sample, the performance is described as an *AB conditional discrimination.* In Sidman's studies, correctly matching pictures to spoken words constituted the AB conditional discrimination.

Sidman's second teaching phase began for each participant once all AB performances were strong. (In fact, his participants were able to match a number of the pictures to words even before training began.) Teaching Phase 2 was conducted exactly as Phase 1 had been, but with one important difference. Instead of the pictures, 20 written words now served as comparison stimuli, with 8 of the words presented on any given trial. Spoken words served again as sample stimuli. (See Figure 19.2.) Thus, Phase 2 was designed to establish an *AC conditional discrimination.*

This training phase took some time to complete, and for two participants (from Sidman & Cresson, 1973) the words were taught in increasing set sizes; first, 9 words were taught to a mastery criterion, then 5 more words were added for a total of 14, and then all 20 words were presented together. When all AB and AC performances were strong, the important questions could then be addressed. Had these young men acquired skills that might reasonably be described as true reading comprehension? Did they really understand the words as symbols, or had they simply learned the rote pairings that had been directly targeted by the training procedures?

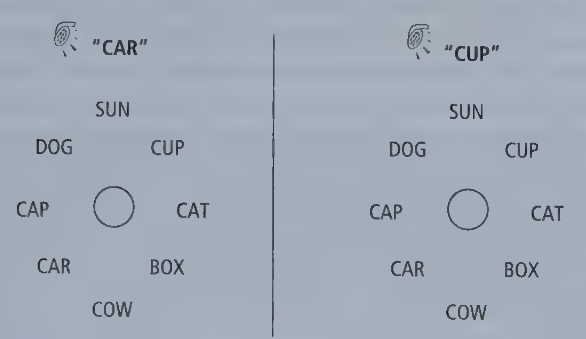

Figure 19.2 An illustration of two trials of the AC matching-to-sample procedure, with the spoken sample stimulus indicated at the top of each diagram.

Adapted from "Equivalence Relations and Behavior: An Introductory Tutorial," by M. Sidman, 2009, *The Analysis of Verbal Behavior, 25*, p. 7.

What Was Learned

To distinguish between the two possibilities, Sidman designed an ingenious series of test or *probe trials*, still presented in the matching-to-sample format, but in the absence of any programmed consequences. In other words, each probe trial was presented under extinction conditions, which allowed interpretations in terms of symbolic, or true matching, function. (In fact, these same tests had been presented at the very start of the studies, prior to any teaching, to determine baseline levels of performance; with the exception of some correct selections on AB trials, as noted above, and some correct picture-naming responses, baseline accuracy levels were uniformly low.) The probe trials presented new combinations of sample and comparison stimuli that were never encountered during training. Thus, any consistent patterns of responding observed on the probes (in the absence of reinforcement) could be described as **emergent stimulus relations**. The term **derived stimulus relations** is sometimes used as a synonym for these emergent performances.[1]

There are four critical types of probe trials in equivalence studies. To illustrate Sidman's training and testing design, Figure 19.3 presents a schematic of the trial types involved, simplified for the sake of space to show only 3 of the 20 stimuli from each training set. Figure 19.4 presents exactly the same information using the alphanumeric stimulus-designation system, to illustrate the relation between the two descriptive approaches. In both formats, arrows point from the sample stimuli, which would be presented individually, to the comparison stimulus array. Solid arrows indicate stimulus relations for which explicit reinforcement contingencies had been arranged during training phases (i.e., the AB and AC conditional discriminations described above). Broken arrows indicate the untrained stimulus relations that could be tested by probe trials. In his 1982 papers (Sidman & Tailby, 1982; Sidman et al., 1982), Sidman provided descriptors for each probe-trial type, taken from the mathematical set-theory definition of equivalence. He reasoned that these behavioral tests captured operationally the abstract mathematical properties said to hold when a set of events are defined as equivalent to one another.

To explain further, after teaching AB and AC conditional discriminations, stimulus **reflexivity** is tested by probes for *generalized identity matching* between each of the experimental stimuli. For example, with stimulus B2 as sample, and stimuli B1, B2, and B3 as comparisons, selecting stimulus B2 would be indicative of reflexivity. Consistent reflexive selections with all of the experimental stimuli (e.g., the pictures and the written words, in Sidman's studies), in the absence of reinforcement for such selections, indicate that each stimulus is functioning as equal to itself. The mathematical statement of reflexivity holds that A = A; thus, generalized identity matching provides an operational definition of the mathematical property. The mathematical statement of **symmetry** holds that if A = B, then B = A or if A = C, then C = A. This property is typically operationalized by probe trials that reverse the roles of the

"Efficiently Establishing Concepts of Inferential Statistics and Hypothesis Decision Making through Contextually Controlled Equivalence Classes" by D.M. Fienup and T.S. Critchfield, 2010, Reproduced with permission of John Wiley & Sons Inc.

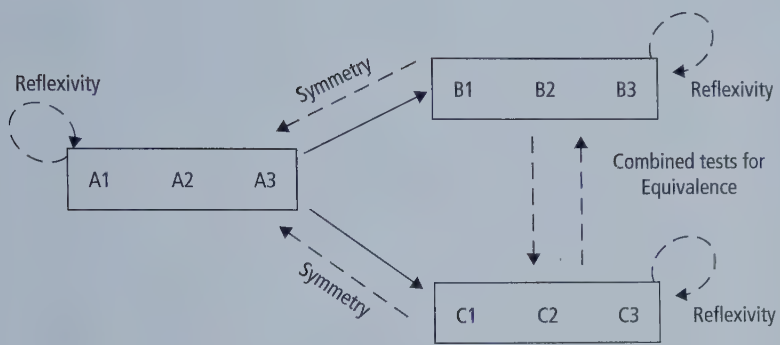

Figure 19.4 Schematic representation of the trained and tested conditional discriminations, with individual stimuli indicated by their alphanumeric designations.

stimuli presented as sample and comparisons during training. For example, after learning to select the appropriate B comparison given an A sample (i.e., selecting B1 given A1, B2 given A2, and B3 given A3), a symmetry probe would present one of the B stimuli as a sample, with A1, A2, and A3 as the comparison choices. Similarly, after establishing selections of the appropriate C comparison stimulus given an A sample, probe trials would present each of the C stimuli as samples with A1, A2, and A3 as the comparison array. Consistent patterns of reversible stimulus selections (e.g., choosing A1 given B1, or choosing A2 given C2), again in the absence of reinforcement for the selections, across all relevant probe trials would demonstrate the property of symmetry. The young men in Sidman's early studies received a modified version of the typical symmetry probes because the A stimuli in their training consisted of spoken words, and it is difficult to present multiple spoken words simultaneously as choices for selection. Instead of the standard symmetry test, then, each of the B and C stimuli was presented individually, and the participant was asked to name it (a tact or textual response, respectively), arguably a more demanding task, as the appropriate response had to be produced rather than selected from an array. Nevertheless, the exciting result was that these boys not only named the pictures correctly but also read the written words; that is, they read the words orally where they had been unable to do so prior to the teaching phases, despite the fact that oral reading had not been directly targeted during training, and despite the fact that no reinforcers were available on the probe trials. This was a striking accomplishment, but did the boys understand the meaning of the words?

A third probe-trial type evaluated this possibility. The mathematical statement of **transitivity** holds that if A = B, and if B = C, then A = C, and when both symmetry and transitivity hold, C = A. This latter arrangement is often described as a *combined test for equivalence*, or even more simply, an **equivalence test**, because both properties are evaluated simultaneously. The participants in the present studies had received AB and AC training; thus, their combined tests for equivalence involved either B stimuli presented as samples with C stimuli as comparisons, or the converse—C stimuli as samples with B stimuli as comparisons (i.e., if A = B, and if A = C, then B = C and C = B). On some probe trials, a picture (from stimulus set B) was presented first and the task was to select the matching written word (from stimulus set C). On other probe trials, a written word was presented first, and the task was to select the matching picture. All 20 of the possible picture-word combinations were evaluated in this way. Consistent and appropriate matching of pictures to words (e.g., selecting a picture of a sun when the sample was the written word "SUN," or selecting the written word "CAR" when the sample was a picture of a car), again in the absence of reinforcement for the selections, across all relevant probe trials would demonstrate the combined properties of symmetry and transitivity. More importantly for these young men, such consistent patterns would also represent true reading comprehension, an indication that the meaning of the words was understood. Sidman (2007) describes observing the first probe trials conducted with these young men; he and his colleagues watched from behind a one-way mirror, all with baited breath. As one correct response after another was demonstrated, the scientists literally danced, and at the end of the session, the research assistant jumped up, hugged the participant, and shouted, "Kent, you can read!" (Sidman, 2007, p. 315). This excitement on the part of the researchers helps to communicate the power and the potential of the outcome that had just been observed. Indeed, all three of the young men involved went on to show the emergent patterns

indicative of oral reading and reading comprehension for the first time in their lives, even though these particular performances had not been directly taught.

To complete our lesson on basic equivalence terminology, when successful performances like those just described are obtained on probe trials of all three types—reflexivity, symmetry, and transitivity (or combined tests for equivalence)—in the absence of reinforcement, the defining criteria for **equivalence-class formation** are satisfied. In the studies at issue here, 20 different stimulus classes, each including a spoken word, a picture, and a printed word (i.e., A1B1C1; A2B2C2; . . . A20B20C20) could be characterized as *equivalence classes* in that the members of each class were perfectly interchangeable within a given context. Said another way, each stimulus from a given class functioned identically, whether as a sample or as a comparison stimulus, in relation to any other member of the same class. It is exactly this emergent interchangeability that allows us to interpret the stimuli within each class as symbolic of one another (e.g., a symbolic relation was demonstrated between the spoken word, "car," the written word, [CAR], and the picture of the car). What's more, this interchangeability was the result of a structured teaching approach involving only a small subset of the total number of relations generated.

Why It Mattered

The reading accomplishments of these three young men thus served to inspire the study of equivalence on multiple fronts. First, new forms of stimulus control were created that had never been targeted directly by the teaching procedures. Consider the productivity of the approach taken in these cases: 20 AB (spoken word–picture) and 20 AC (spoken word–written word) relations either were already demonstrated by these participants or were explicitly established by the reinforcement contingencies of the matching-to-sample training procedure. The resulting performances included those 40 relations, as well as the potential for 60 new reflexivity relations, 40 new symmetry relations, and 40 new combined equivalence relations, for a grand total of 180 discriminated operant units! This production of reliable and predictable patterns of novel stimulus-control relations, particularly when the novel control is not based on physical similarities across the stimuli (as in primary stimulus generalization), is a striking behavioral phenomenon, demanding of research in its own right, just to understand the processes that might be responsible. Prior to Sidman's work (Sidman, 1971; Sidman & Cresson, 1973; Sidman & Tailby, 1982), there was nothing within an extensive behavior analysis literature to suggest such generative capacity after basic four-term contingency training. A tremendous research effort has followed.

A second reason for immediate excitement about Sidman's early findings followed unequivocally from the first, and is perhaps most relevant to the content of this textbook. Given the focus on reading in Sidman's studies, the potential for utilizing an equivalence approach to promote teaching efficiency was immediately apparent. Sidman's early successes had captured that holy grail of applied outcomes—establishing extensive, varied, and flexible repertoires with only a modicum of direct training. The way had been paved for creative extensions of the equivalence approach to behavioral targets across a broad spectrum of academic and functional life skills, a number of which will be reviewed in the pages that follow.

A third striking feature of the equivalence outcome just described is the degree to which it captured the essence of what is meant when we speak of a "symbol." The three defining probe-trial types revealed that an arbitrary sound (i.e., a spoken word), an abstract set of black-and-white markings (i.e., a written word), and a related picture were each treated identically and interchangeably, just as would be expected of a symbol and its referent. This sort of substitutability has often been described in terms of a symbol "standing for," or "meaning the same as," its referent; however, a clear specification of the behaviors necessary for identifying a true symbol had long been lacking (e.g., Sidman, 1994; Wilkinson & McIlvane, 2001; Box 19.1 provides an example of the confusions that often result). Sidman's equivalence criteria had thus established a compelling operational definition of symbolic function. In so doing, these criteria also provided a basis for empirical behavioral analysis of other complex performances critical to much of human behavior (e.g., categorization, semantic correspondence, syntax), as well as a possible approach to the development of (or change to) these sorts of performances as clinical targets. One case in point involves the study of behavioral novelty or creativity. Indeed, creativity has sometimes been erroneously characterized as unamenable to behavioral accounts, given that a history of reinforcement is lacking, by definition, when a behavior occurs for the first time. With equivalence procedures, however, novel behavior is illustrated reliably and in predictable patterns by the emergent performances on probe trials. Other examples of extensions to complex human functioning include equivalence-based models of instruction following, social stereotypes, false memories, and clinical issues such as the spread and treatment of generalized anxiety or phobias, just to mention a few.[2] An important shared characteristic of these complex patterns of responding is the involvement of emergent symbolic function.

Continued Development of Equivalence Research: Key Outcomes Obtained with Equivalence Approaches

Recent years have seen a repeated emphasis on the importance of *translational research*, both for science in general (e.g., Woolf, 2008; Zerhouni, 2005) and for behavior analysis in particular (e.g., Critchfield, 2011; Mace & Critchfield, 2010). A traditional conceptualization of translational research has focused on moving the findings from our basic laboratory science into the hands of practitioners, where our increased understanding can be put to important functional ends. In fact, this pragmatic strategy has been a defining characteristic of behavior analysis since its early formulations. "What we call the scientific conception of a thing is not passive contemplation. When we have discovered the laws which govern a part of the world about us, we are then ready to deal effectively with that part of the world" (Skinner, 1953, p 13). At the same time, behavior analysts have long realized that when those behavioral principles emerging from our labs are applied to significant social problems (Bear, Wolf, & Risley, 1968, 1987), additional critical questions about the principles and their operation inevitably arise. This often necessitates a return

BOX 19.1

But I Know My Dog Understands Me

We often hear heartwarming stories in the media about clever pets—especially dogs—who understand their owner's words so well that they perform life-saving rescues (remember Timmy telling Lassie to go get help?), even calling 911 and barking into the phone. Indeed, well-trained dogs help owners with mental health issues cope with emotional overload; they follow commands from owners with physical disabilities to retrieve dropped items, open and close doors, and provide support for standing and walking; and they fetch medications, phones, and other items for the elderly in emergency situations. There are reports of dogs who recognize more than 1000 human words, and one recent functional magnetic resonance imaging (fMRI) study (Andics et al., 2016) found different types of brain activity when dogs were presented with meaningful words in either a praising or a neutral tone compared to meaningless words presented as praise. Further, many dog owners are convinced that their pets understand not only their words but their emotions as well; we all know pets who respond very differently in the face of an owner's laughter versus tears. Surely these reports, and scads of others like them, document that dogs understand what we say, right?

This question gets right to the heart of what it means to speak of "understanding a word." To pose the issue a bit differently, is there any reason to believe that a dog's response to "Sit," for example, differs from a child's, or from our own, for that matter? In all three cases, the appropriate bodily position may be executed perfectly and immediately upon hearing the verbal command, so observation of that particular interaction does little to reveal a distinction between the three instances. Nevertheless, should we feel comfortable concluding that the dog in question actually understands the meaning of the word "Sit" in the same sense that the child does? Is "Sit" a true symbol for a certain action or posture, or is the dog's "understanding" limited to performing a single response that has been explicitly trained in the presence of a specific discriminative stimulus? These are essentially the same questions Sidman was grappling with in his early equivalence studies (Sidman, 1971; Sidman & Cresson, 1973; described above), when he sought to find out whether the match-to-sample teaching procedure had produced true reading comprehension for the boys who participated. When the boys came to choose the appropriate written word upon hearing it spoken after repeated reinforcement for doing exactly that, did they understand the meaning of the words, or were they simply performing a trained rote response? As with the dog example, accurate selection of the directly trained option, in and of itself, did not reveal an answer. Further indicators, beyond the explicitly reinforced behavior patterns, are needed to make judgments about understanding, comprehension, and symbolic function. To return to the "Sit" example, after learning to take a seat when asked to, a child might then also request that her mother "sit" in an appropriate circumstance, accurately label or describe other people as sitting, match "Sit" with pictures of novel individuals doing so, and point out suitable objects on which one might sit, all in the absence of further teaching. These novel or emergent performances provide the types of evidence necessary to reflect understanding of the word. In contrast, responses to "Sit" for even the cleverest pets would likely be limited to executing the one physical position they had been taught to perform. Dogs may indeed be taught to make specific and even useful responses when presented with many different spoken words, which is impressive, to be sure. It falls short, however, of demonstrating true symbolic understanding.

Of course, operationalizing exactly what is needed to convince us of understanding and comprehension provided the impetus for Sidman's development of equivalence, or symbolic matching-to-sample, as characterized by the properties of reflexivity, symmetry, and transitivity (Sidman & Tailby, 1982). Indeed, ever since those defining features were first introduced, the possibility that equivalence patterns might be demonstrated by (nonhuman) animals has been a topic of considerable research activity. Early work on the topic found little support for responding consistent with the properties of equivalence, particularly symmetry, with species ranging from pigeons (e.g., Hogan & Zentall, 1977), to *Cebus* monkeys (D'Amato, Salmon, Loukas, & Tomie, 1985), to rhesus monkeys and baboons, (Sidman et al., 1982), and even to chimpanzees (e.g., Dugdale & Lowe, 1990). More recent work has focused on the very real possibility that the experimental procedures designed for humans may not be optimal for assessing equivalence-class formation in animals—in other words, we may have been asking questions of our animal subjects in the wrong ways. Methodological arrangements better suited to the strengths and learning styles of a given species (e.g., using olfactory stimuli with rats; Pena, Pitts, & Galizio, 2006) have yielded some promising leads. Interestingly, some of the most compelling evidence to date for equivalence-class formation in animals has come from two sea lions, Rocky and Rio (Kastak, Schusterman, & Kastak, 2001).

The experimental histories of these subjects took place over many years, and included extensive training on a number of related tasks, so the complete set of factors responsible for their strong test performances cannot be specified. You can rest assured, however, that the search for equivalence in animals is alive and well in research labs around the world (e.g., Galizio & Bruce, 2017).

to the lab for further investigation, followed by a new round of refined applications, and so the cycle continues. In this way, translational research represents a reciprocal and dynamic process in which the laboratory and the field inform and inspire each other, leading to increased effectiveness in both domains, and providing for the strength of behavior analysis as a discipline. For present purposes, there is perhaps no better example of a translational research agenda than the one that has characterized stimulus

equivalence. The equivalence-research story is especially notable in this context in that the core phenomenon was brought to light initially in an application, reading instruction, which then demanded laboratory follow-up, rather than the other way around—a valuable exemplar for applied behavior analysts and basic researchers alike. Since Sidman's landmark studies, many hundreds of basic laboratory analyses have investigated the conditions necessary and sufficient for equivalence-class formation, while equivalence applications have benefited learners ranging from young typically and atypically developing children, to college students, to adults with brain damage and dementia. As this body of work developed and progressed, several key outcomes were identified that added fuel to excitement about the scope and power of equivalence approaches for applied behavior analysis. These outcomes include class formation, expansion and merger, transfer of function, and contextual control.

Class Formation

The outcome of primary importance in any study of equivalence is demonstration of the emergent performances that indicate stimulus interchangeability and thus the formation of equivalence classes. The defining criteria for interpretations of equivalence have traditionally included strong and stable class-consistent responding on reflexivity, symmetry, and transitivity/equivalence probe trials in the absence of reinforcement (e.g., Sidman & Tailby, 1982; see the dashed lines in Figures 19.3 and 19.4 for illustration of these critical tests). The most common measure of class formation has been the percentage of probe trials on which a comparison selection is consistent with equivalence, for each defining property. For example, after training AB and AC conditional discriminations, stimulus C1 would be presented as the sample on some probe trials; selecting C1, A1, or B1 would be consistent with equivalence-class formation on probes for reflexivity, symmetry, or combined tests for equivalence, respectively. (Again, see Figure 19.4.)

To illustrate, Figure 19.5 provides data from one of Sidman's original participants (Sidman & Cresson, 1973). The three panels present outcomes on the test types of particular interest in that study: word-name relations (i.e., textual responses, or CA oral naming) in the top panel, with picture–printed word (BC) and printed word–picture (CB) relations (i.e., reading comprehension) in the middle and bottom panels, respectively. The trial types were intermixed in the actual test administration but are separated in this figure so that each performance can be followed individually. Each bar represents the percentage of responses on a given probe-trial type (CA, BC, or CB) that were consistent with the potential equivalence classes, for each of a series of test administrations. (As a reminder, 20 three-member classes were made possible by the training, where each class included a spoken word, a picture, and a written word.)

In this study, four pretest administrations were conducted over the course of approximately 1 year. This type of pretesting is often required in studies of equivalence-based instruction when the stimuli targeted for training are common ones found in everyday environments. Pretest results play an important role in judging whether the performances of interest may have been due to learning that occurred outside the programmed

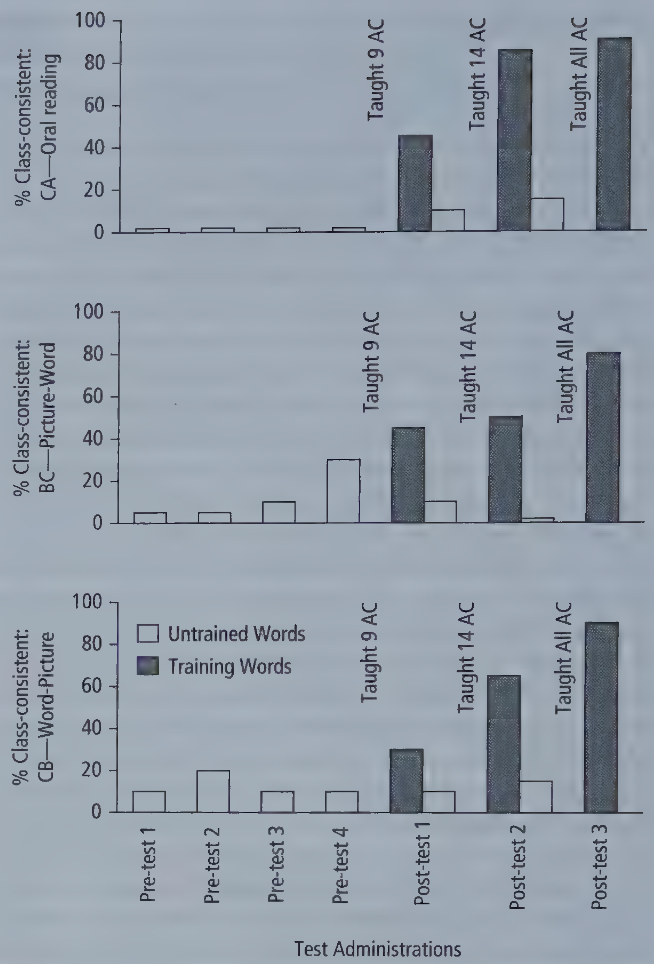

Figure 19.5 Percentage of trials on which class-consistent comparisons were selected for each of three probe types, CA (top panel), BC (middle panel), and CB (bottom panel). Each bar or pair of bars represents data from a single test administration. Open bars show performances on trials with words that had not been involved yet in training; filled bars show performances on trials with words that had been part of training.

Adapted from "Reading and Crossmodal Transfer of Stimulus Equivalences in Severe Retardation," by M. Sidman and O. Cresson, 1973, *American Journal of Mental Deficiency*, *77*, p. 515–523.

instruction under evaluation. In the present case, the percentage of class-consistent responses was consistently low for each of the three probe types across the four pretests, never exceeding chance levels of accuracy, despite repeated practice with each test and despite the fact that the 20 spoken words were being matched with their appropriate pictures (that is, the AB relations had already been learned). Thus, pretest results indicated that the performances of interest were not improving as a result of ongoing extra-experimental experiences for this participant. The AC spoken word–written word relations were taught in three separate instructional phases involving 9, then 14, and then all 20 of the words. A posttest with all 20 words followed each teaching phase. Results from the first two posttests are presented with two bars. The filled bars indicate scores on trials with written words that had been included in the preceding teaching phase, and the open bars indicate scores on trials with written words that had

not yet been taught. By the third posttest, all 20 of the written words had been included in training. Posttest results were similar across the probe-trial types. The percentage of class-consistent responses increased well over pretest levels for each posttest, but only when the trials included a word from the training set. Responding remained at approximately chance levels for those trials involving an untrained word. This important finding indicates that improvements were specific to the instructional procedure, as opposed to some other extraneous factor (e.g., increased motivation or task familiarity, classroom experiences outside the experiment). By the final posttest, class-consistent responding was very strong, at 80% or better, for all probe types, indicating the formation of 20 three-member equivalence classes.

This example illustrates well the type of data and the experimental reasoning that characterize conclusions about equivalence-class formation. While the specific criteria required to make judgments about class formation vary slightly across studies, depending on procedural details, they are always quite high (e.g., 90% class consistency or greater across probe types), and often include further specification that the number of inconsistent responses made on any given probe type is low (e.g., no more than a single error per probe type).

With many participants, equivalence outcomes are observed immediately, on the very first probe tests. However, another relatively common finding, known as *delayed emergence*, is that probe responses become increasingly consistent with class formation as testing continues, sometimes beginning at chance levels and improving to perfect or near-perfect class consistency across test administrations, despite the absence of consequences on these trials (e.g., Sidman, Kirk, & Willson-Morris, 1985; Spradlin, Cotter, & Baxley, 1973). In fact, the data from Figure 19.5 illustrate this pattern. Even for the words that had been included in training, the percentage of class-consistent probe responses increased across the successive posttests. Delayed emergence has important implications for conclusions about equivalence "failures" when probe exposure has been limited, and its frequent occurrence suggests that tests should be repeated when initial performances are weak, especially if the data suggest an improving trend.

Class Expansion and Class Merger

If equivalence-based instruction is to provide a basis for generating truly functional repertoires, class size becomes an issue of interest. In the studies described thus far, three-member equivalence classes (e.g., a spoken word, picture, and written word; Sidman, 1971; Sidman & Cresson, 1973) were produced, this being the minimum number of members necessary to demonstrate all equivalence properties. While clearly valuable, and often a huge improvement from beginning skill levels, three-member classes might not take a child (or adult) very far toward fluency in verbal behavior, numeracy, coin usage, categorization, and so on. Fortunately, equivalence outcomes known as **class expansion** and **class merger** have been studied and documented extensively (e.g., Saunders, Saunders, Kirby, & Spradlin, 1988; Saunders, Wachter, & Spradlin, 1988), providing strong evidence that classes can be increased to include a potentially unlimited number of members. Importantly, as class size increases, the number of generative or emergent performances also grows exponentially.

In class expansion, a new member is added to demonstrated equivalence classes, typically by teaching a new conditional discrimination. One member from each of the original classes serves as either sample or comparison in the new training, and a novel stimulus set serves in the alternative role. To illustrate, consider again the equivalence classes demonstrating Sidman's reading work, where each class included a spoken word, a picture, and a written word (A1B1C1, A2B2C2, etc.). Suppose that for the young men involved, learning the corresponding signs from American Sign Language would also have been useful for their living circumstances. EBI could be used to expand their three-member classes to four members by teaching the young men to match the signs to spoken words. In other words, the signs could be presented as comparison stimuli (e.g., D1, D2, D3) with the spoken words serving as samples (e.g., A1, A2, A3), and an AD conditional discrimination could be taught by reinforcing the appropriate comparison selections. Figure 19.6 illustrates the new training with a solid gray arrow. Class expansion would be evidenced by equivalence-consistent responses (e.g., selecting the appropriate sign given a picture or written word; selecting the appropriate written word or picture given the sign) on probe trials DA, BD, CD, DB, and CB. Figure 19.6 illustrates all of the newly possible emergent relations with dashed gray arrows. Note that after teaching one additional conditional discrimination (AD), a total of six new relations are created for each equivalence class (i.e., AD, DA, BD, DB, CD, and DC), dramatically increasing the impact of a small amount of teaching. Instructing additional conditional discriminations, one by one, can produce a gradual increase in class size from three, to four, to five members or more, even with young children (e.g., Lazar, Davis-Lang, & Sanchez, 1984).

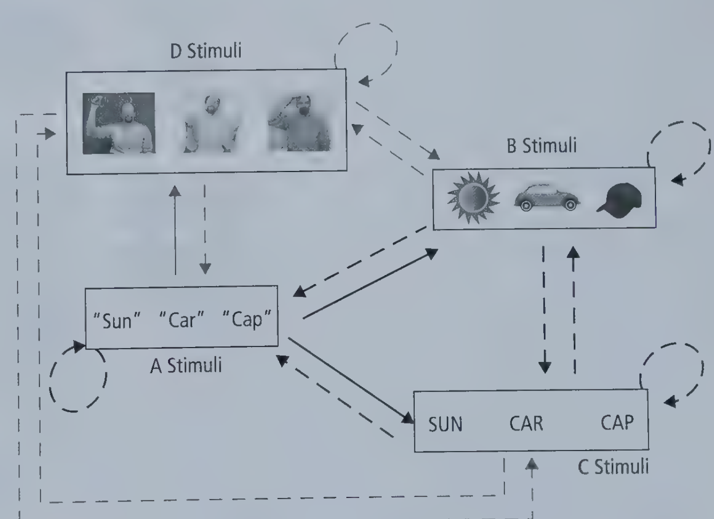

Figure 19.6 Schematic representation of trained and tested conditional discriminations. The solid gray arrow indicates the new conditional discrimination training, and the dashed gray arrows represent the new emergent relations made possible by the training.

In class merger, independent equivalence classes can be combined to produce a larger class by teaching a new but interrelated conditional discrimination. Consider the teaching arrangement illustrated in Figure 19.7, which might be appropriate for young children or individuals with intellectual disabilities who lack coin skills. Here, teaching AB and AC conditional discriminations could result in two three-member equivalence classes, one including the spoken word, "Dime," the printed stimulus, 10¢, and an actual dime (i.e., A1B1C1), and the other including the spoken word, "Quarter," 25¢, and an actual quarter (i.e., A2B2C2).[3] As usual, we would look for evidence of these classes having formed by presenting the test trials represented by the dashed lines. Next, two additional conditional discriminations, DE and DF, are taught. Again, performances on the tests represented by the dashed lines would evaluate the formation of two new equivalence classes, one including the spoken "10 cents," two nickels, and five pennies plus a nickel (i.e., D1E1F1), and the other including "25 cents," two dimes plus a nickel, and five nickels (i.e., D1E2F2). At this point a total of four independent three-member classes have been made possible by the training.

Once class-consistent probe performances confirm the formation of these classes, Figure 19.8 illustrates an additional teaching step that could result in class merger. The bold solid arrow shows that one more conditional discrimination—CE—is taught. Given 10¢ or 25¢ as a sample stimulus, reinforcers would follow selection of two nickels or two dimes plus one nickel, respectively.

Class merger describes an outcome in which stimuli from the originally independent classes A1B1C1 and D1E1F1 are matched to each other, such that a single six-member class (A1B1C1D1E1F1) emerges. In our example, the spoken words, "Dime" and "10 cents," the written stimulus, 10¢, and each appropriate coin arrangement, whether a dime, two nickels, or five pennies plus a nickel, could all prove to be completely interchangeable. Similarly, the six stimuli relevant to the "quarter" class could merge and become interchangeable for a second six-member class (A2B2C2D2E2F2). In short, the four original equivalence classes, composed of three members each, could give rise to two six-member classes. Figure 19.9 represents with dashed gray arrows all of the emergent relations made possible by teaching the CE conditional discrimination, and those that would have to be tested to reach conclusions about class merger. Positive, class-consistent responding across the various probe types would provide not only a basis for important functional skills in coin usage but also exactly the evidence necessary for inferences about understanding or comprehension of the symbolic relations between these stimuli. The network of new performances illustrated also paints a striking picture of the generative potential of equivalence-based instruction, especially as class size increases. Indeed, the balance of solid arrows (directly taught relations) to dashed (emergent relations) for the figure as a whole captures nicely the "bang for your teaching buck" impact of equivalence-based teaching procedures.

Class merger outcomes like those just described have been demonstrated repeatedly in the equivalence literature, and with many populations, including typically developing children and adults (e.g., Sidman et al., 1985; Johnson, Meleshkevich, & Dube, 2014), as well as participants with intellectual disabilities (e.g., Lane & Critchfield, 1998; Saunders, Saunders, Kirby, & Spradlin, 1988). To date, few limits have been identified for the size of equivalence classes that can be generated through expansion or merger, although this would likely depend on the particular participant or participant population. Indeed, it has even been suggested that measures of the number of members that can be added to an equivalence class, either sequentially (as

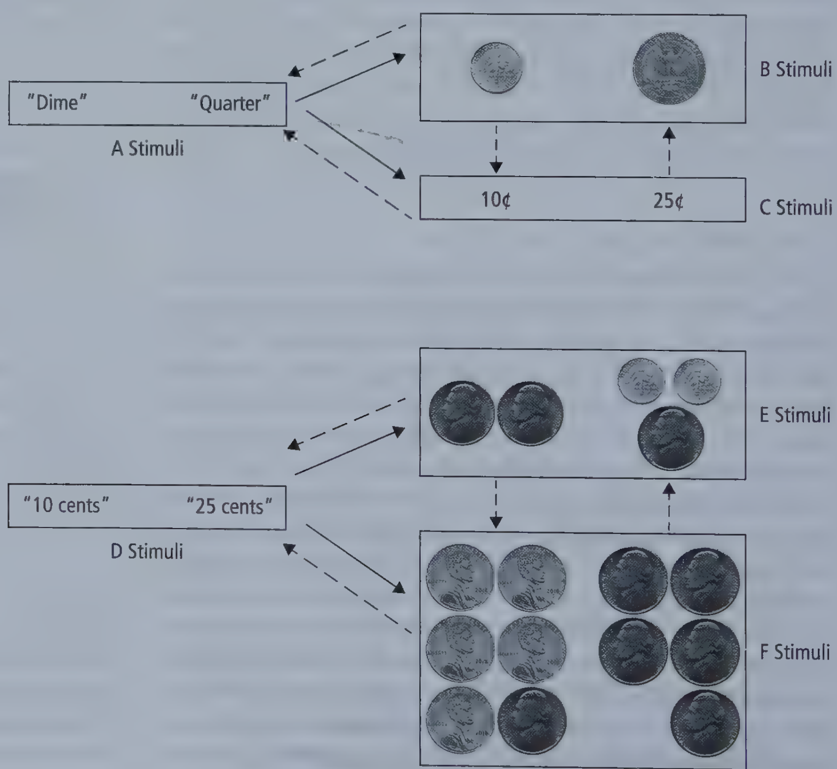

Figure 19.7 Schematic representation of trained (solid arrows) and tested (dashed arrows) conditional discriminations for two training phases, one for AB and AC conditional discriminations and one for DE and DF conditional discriminations.

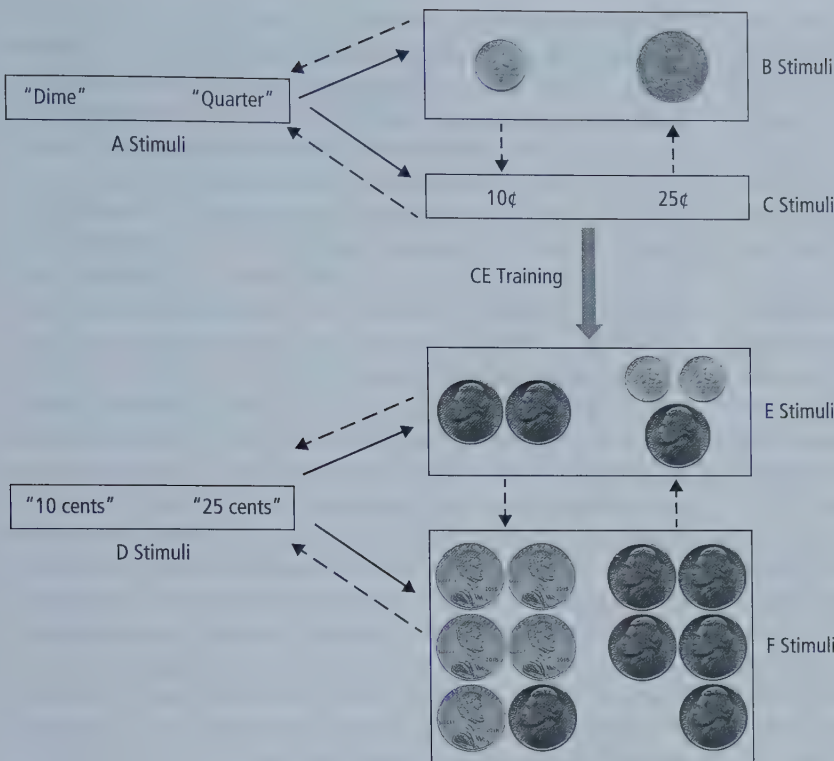

Figure 19.8 Schematic representation of trained (solid arrows) and tested (dashed arrows) conditional discriminations for the first two training phases, as well a third training phase. The bold solid arrow indicates the added CE conditional discrimination training.

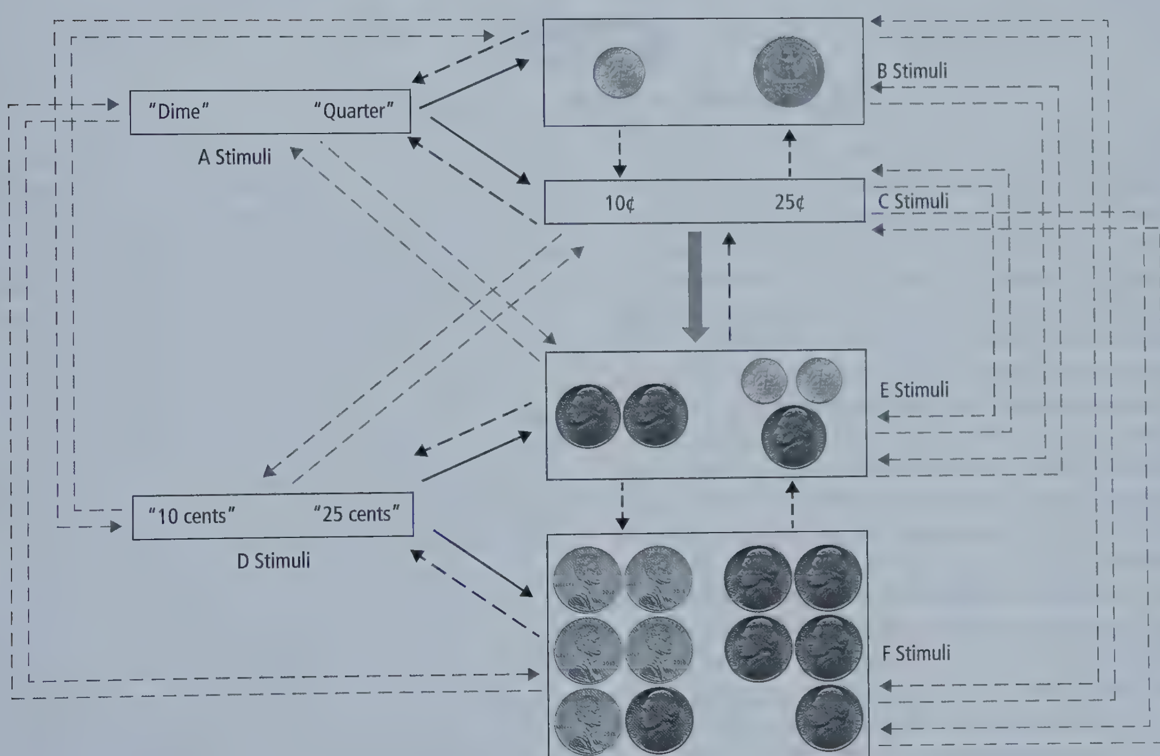

Figure 19.9 Schematic representation of trained (solid arrows) and tested (dashed arrows) conditional discriminations for all training phases. The bold solid arrow indicates the added CE conditional discrimination training that made class merger possible. The dashed gray arrows indicate the many relations that could result from class merger.

in class expansion) or simultaneously (as in class merger), might provide a more valid assessment of cognitive development or of recovery from brain injury than the standardized tests currently in use (e.g., Sidman, 1986a; 1994).

Transfer of Function

A third major finding from research on stimulus equivalence, described as **transfer of function**, adds even further power to the generative potential of EBI. When a group of stimuli are said to be

equivalent, the implication is that each of the stimuli in the group will function in the same manner: that each is interchangeable with any other. As we have reviewed, this interchangeability of function is assessed by tests of reflexivity, symmetry, and transitivity/equivalence in which each member of the class proves to serve equally well in relation to any other member of the class, no matter which stimulus combinations are presented as sample and comparison. But what if a new function—that is, a stimulus-control effect other than that of sample or comparison in a match-to-sample task—was taught for one member of an equivalence class? If the stimuli that compose a given class are truly equivalent, it would follow that the new function should be shared by all members of the class—in other words, that the function should transfer to all class members.

Let's continue with the coin-equivalence example from Figure 19.9 and assume that our students have demonstrated the two possible six-member classes. As a next teaching step, we'll establish a new function for the dime and the quarter (B1 and B2). First, we'll teach that the dime can be traded for two pieces of candy and that the quarter can be traded for five pieces of candy. When this lesson is mastered, we'll provide a choice between the dime and the quarter: "Which one would you like to have?" Selection of the quarter would confirm that our teaching procedure established a new function for each coin—that the quarter is better than or worth more than the dime. Subsequent tests would then present the same choice with each pair of stimuli (A1 and A2, C1 and C2, D1 and D2, etc.). Consistent selections of A2, C2, D2, E2, and F2 (instead of A1, C1, D1, E1, or F1) would demonstrate the transfer-of-function effect in that each member of the quarter class is preferred to, or better than, a member of the dime class, despite the absence of direct "value" training for any of these class members.

The transfer-of-function effect has been demonstrated in a great many ways, shapes, and forms, and for many different stimulus functions (e.g., Green, Sigurdardottir, & Saunders, 1991; Kohlenberg, Hayes, & Hayes, 1991; Smeets & Barnes-Holmes, 2003), highlighting the possibilities for emergent equivalence-based performances that go far beyond the matching-to-sample context. Indeed, transfer of function is arguably among the most important advantages of classes or categories; once a class has formed, anything new learned about one member of the class can hold for all members of the class, without additional training. However, as illustrated in Box 19.2, transfer of function can be implicated in the spread of both adaptive and problematic response patterns. The transfer effect is accounted for from the perspective of equivalence in terms of class merger (e.g., between the established equivalence class members and the class of stimuli that serves a particular function; e.g., Sidman, 1994, 2000). Equivalence-based applications designed to take advantage of transfer-of-function effects are still somewhat limited, but the potential is clear.

BOX 19.2

Are Equivalence Classes Ever a Problem?

A chapter on designing and implementing EBI will necessarily focus on productive uses of this teaching approach. A completely fair question, however, is whether equivalence-class formation might ever have a negative impact on an individual's functioning. As you might guess, in a world in which bad things exist, equivalence classes that include bad things as members are also a possibility. And as we've just reviewed, if one member of an equivalence class has a particular function (e.g., if one member is "bad"), the other members of the class are likely to share that same function—the transfer-of-function effect. As a result, physically dissimilar stimuli might come to be treated as "bad" even if they have never had any direct pairing or correlation with aversive events. Of course, establishing classes of bad things can often be useful, even life-saving. Any parent would be delighted if her child immediately avoided items marked with the signs shown in Figure 19.10, after learning to steer clear of POISON, for example.

In contrast, consider a case in which a college student experiences some difficulty while taking a test in a biology class. For question after question, she realizes that her study the night before was far too superficial, and she cannot compose a single coherent answer. As her heart begins to race and her breathing becomes more rapid, her thinking is increasingly distracted. She rushes from the room with most of the test booklet still incomplete, and thus escapes the unbearable situation. We could all agree that this scenario describes a highly aversive experience. Unfortunately for the student involved, the aversiveness doesn't stop there. She begins to notice the same increased respiration and heart rate with respect to other classes, and not only when taking a test. Preparing for a test, or just the announcement of a quiz, exam, or final, can initiate the cycle of intense emotions. Study patterns are disrupted and absences increase, both for exams and for regular class days (pop-quiz possibilities . . .). Course syllabi with test dates and final exam schedules even become difficult to look at, and registering for a new semester looks bleak.

Patterns like this one—often described in terms of test anxiety—are not uncommon among college students. How might equivalence classes play a role? One possible interpretation (e.g., Augustson, Dougher, & Markam, 2000; Dougher, Augustson, Markham, Wulfert, & Greenway, 1994; Friman, Hayes, & Wilson, 1998) goes as follows: For college students, it is not hard to imagine an equivalence class that includes actual tests; the spoken and written words "Test," "Exam," "Quiz," and

Figure 19.10

"Final"; materials describing schedules of such events; and even larger academic units comprising these events (like courses or semesters). The various members of this suggested class share few physical features but may be interchangeable within a given context. To the extent that they are equivalent, then, a frightening experience with one member of the class could result in strong emotional reactions to other members of the class; that is, the function of one member could transfer to them all.

The feasibility of this conceptual account of anxiety has received some strong support from laboratory models. To illustrate (Dougher et al., 1994), a group of college students demonstrated the formation of two four-member equivalence classes (A1B1C1D1 and A2B2C2D2) following match-to-sample training with abstract stimuli. Trials were then presented with either stimulus B1 or B2 on the computer screen. When B1 appeared, a brief electric shock was also presented; when B2 appeared, no shock occurred. In the next phase of the study, the other class members were presented, one at a time. Stimuli C1 and D1 elicited skin conductance responses (a common laboratory measure of emotional reaction) similar to those produced by B1, while C2 and D2 did not (Dougher et al., 1994), demonstrating the transfer of an elicitation function from B1 to C1 and D1. In a second experiment, the eliciting function of B1 was extinguished by presenting that stimulus multiple times in the absence of shock. Subsequent tests with each stimulus presented individually showed that the eliciting function of C1 and D1 had also extinguished. These interesting results were interpreted as a possible model of phobic response patterns, in which relatively innocuous settings or events can come to occasion severe, even debilitating, anxiety and fear, despite the sufferer reporting no bad experiences with the setting or event at issue. The study confirms that a negative experience need not have taken place in the presence of a current anxiety trigger, depending on the stimuli with which it shares equivalence-class membership. That extinction functions could also transfer across class members is potentially relevant to the effectiveness of certain clinical treatments for phobias (Dougher et al., 1994), such as systematic desensitization (e.g., Koegel, Openden, & Koegel, 2004; Wolpe, 1961).

In sum, that same generativity of equivalence classes that provides for great effectiveness in creating productive repertoires has the potential to result in an equally broad impact of unwanted learning experiences. A similar analysis has been applied to social stereotypes—both positive and negative—where learning about a characteristic of one member of an established group is then extended to other individuals on the basis of nothing more than their group membership (e.g., Kohlenberg et al., 1991; Moxon, Keenan, & Hine, 1993).

Contextual Control

An essential characteristic of many everyday classes or categories is that class composition can shift, sometimes dramatically, depending on the context. For example, the events that might be included in a class of "good plays" would be altered considerably if conversation changed from sports to theater. Similarly, a list of musicians would be sorted quite differently, depending on whether one was asked about musical genre, time period, or nationality. In other words, the very same stimuli can be members of different classes, depending on the context. And, of course, we often note that the meaning or function of a word or phrase depends on the context in which it occurs: We respond differently to the word "right" when we follow directions to a destination and when we receive feedback on an answer to an exam question. If the study of equivalence classes is to be useful in our understanding of naturally occurring classes and categories, including language, this same sort of flexibility in class membership must be captured—and it has been, in investigations of **contextual control** over equivalence classes (e.g., Bush, Sidman, & de Rose, 1989; Lynch & Green, 1991; Wulfert, Greenway, & Dougher, 1994). Box 19.3 describes the role of contextual control in some common (pun intended) forms of humor.

Contextual control in these examples is the result of a more complex teaching arrangement known as a five-term contingency (e.g., Sidman, 1986b, 2000), where the match-to-sample performances described previously are brought under the control of an additional antecedent stimulus. Following from our musicians example, with a context of "Nationality" and the Rolling Stones as a sample (A1), Fairport Convention (B1) would be the appropriate choice (both bands are British); with Bob Dylan as a sample (A2), The Doors (B2) would be the best match (as American musicians). Conversely, if the conversation topic (i.e., the context) turned to music genre, The Doors (B2) would be matched to the Rolling Stones (A1; both rock), while Fairport Convention (B1) would be matched to Bob Dylan (A2; as folkies).

Said a bit more technically, selecting a given comparison stimulus (e.g., B1) is reinforced in the presence of a particular sample (e.g., A1) in one condition (i.e., Context 1), while selecting a different comparison stimulus (e.g., B2) in the presence of the same sample (e.g., A1) is reinforced in a different condition (i.e., Context 2). Similarly, selecting B2 is reinforced given sample A2 in Context 1, while selecting B1 is reinforced in Context 2. The correct match thus depends not only on the sample stimulus presented but also on the context. The question of interest for present purposes is whether training conditional discriminations under contextual control will give rise to equivalence classes that are also under contextual control.

To date, work with contextual control over equivalence classes has primarily involved typical adult participants, so extending this research to other participant populations will be important. However, there has been some use of contextual control procedures in equivalence-based instructional packages designed for college coursework. For example, Fienup and Critchfield (2010; see also Fienup, Critchfield, & Covey, 2009) taught concepts of inferential statistics and hypothesis testing to college students using a computerized equivalence approach, with tests on the lesson content presented before and after training. Figure 19.11 illustrates the teaching and testing arrangement, with trained relations shown

BOX 19.3

Why Are Puns Funny?

A pun is defined as "the usually humorous use of a word in such a way as to suggest two or more of its meanings or the meaning of another word similar in sound" (Merriam-Webster). Sometimes puns make us laugh, other times they make us groan; we may even apologize for a pun (e.g., as in "no pun intended"), as if punning is in bad taste. It has been argued variously that "Puns are the highest form of literature" (attributed to Alfred Hitchcock) and that "Puns are the last refuge of the witless" (attributed to Samuel Johnson), but authors from Shakespeare to Lewis Carroll to James Joyce to Oscar Wilde have all been recognized for their puns. Why would this form of word play evoke such different reactions, and what is it really that tickles us, or not, when puns are used?

Consider these examples:

- I wondered why the baseball was getting bigger. Then it hit me.
- I saw an ad for burial plots, and thought to myself, this is the last thing I need.
- "Denial ain't just a river in Egypt." (Mark Twain)
- A Freudian slip is when you say one thing but mean your mother.
- You matter. Unless you multiply yourself by the speed of light. Then you energy.
- "I went to a place to eat. It said 'breakfast at any time.' So I ordered French toast during the Renaissance." (Stephen Wright)
- And my personal favorite—"Time flies like an arrow. Fruit flies like a banana." (Groucho Marx)

Are we groaning yet? In everyday terms, we could describe each of the instances above as including at least one word with multiple meanings, either for the same word (e.g., "matter" can refer to physical substance or to importance, "flies" can refer to the insect or to speed) or for one that sounds the same (e.g., "denial" and "the Nile," or "your mother" and "another"). In more technical terms, we could say that, in each case, the word or words on which the joke depends are members of more than one equivalence class. For example, the spoken and written word "flies" is a member of one equivalence class that includes nouns such as the Latin name Diptera; a wide range of winged insects with large compound eyes like house flies, horse flies, and tsetse flies; and descriptors like "pollinators" or "pests." It is also a member of an equivalence class that includes verbs that specify moving through the air, moving at a high speed, moving freely, or simply passing quickly. Typically, when a given word has more than one meaning (as most do), the context in which the word occurs determines its function, and we have seen how contextual control can be responsible for determining the class membership of a particular stimulus (i.e., in this case, whether "flies" is responded to as a member of its noun class or its verb class).

The humor of puns, then, can come about in at least two ways. First, either an ambiguous context is provided such that more than one class membership is possible, or the context is explicitly appropriate to more than one equivalence class; the first two examples above illustrate this type of pun. Alternatively, the pun can be deliberately set up to evoke conflicting classes, as in the last three examples (e.g., Groucho first sets the stage for the verb class of "flies," and then switches to the noun class without much additional warning or context). Where skillful writers or orators typically use context to make the impact of their words more precise, puns from this latter category manipulate the reader/listener's response in opposing directions, thereby creating a smile, but perhaps also the cha-grin of those who are not fans of puns. (Sorry.)

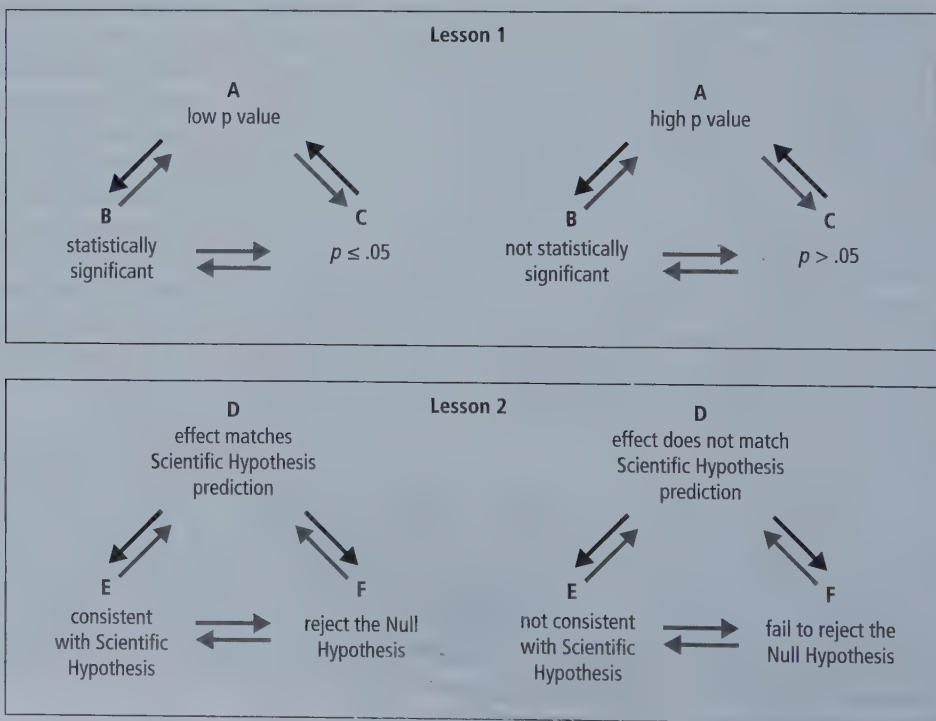

Figure 19.11 Schematic representation of trained and tested conditional discriminations from Lessons 1 and 2, with trained relations indicated by black arrows and tested relations indicated by gray arrows.

"Efficiently Establishing Concepts of Inferential Statistics and Hypothesis Decision Making through Contextually Controlled Equivalence Classes" D.M. Fienup and T.S. Critchfield, 2010, Reproduced with permission of John Wiley & Sons Inc.

by dark arrows and tested relations shown by gray arrows. Lesson 1 established two three-member equivalence classes involving basic concepts related to inferential statistics (A1B1C1 included "low p value," "statistically significant," and "$p < .05$"; and A2B2C2 included "high p value," "not statistically significant," and "$p > .05$"). Lesson 2 did the same with respect to reaching statistical conclusions based on a scientific hypothesis and the direction of an effect in the data (i.e., D1E1F1 and D2E2F2, where D stimuli described a hypothesis and a result, E stimuli were "consistent . . ." or "not consistent with hypothesis," and F stimuli were "reject . . ." or "fail to reject the Null Hypothesis"). Finally, the top panel of Figure 19.12 illustrates Lesson 3, in which contextual control by the A stimuli ("low p value" or "high p value") over DE and DF matching was trained. Note that the correct E or F choice depended on both the D sample and the A contextual stimulus. In other words, selecting "consistent with Scientific Hypothesis" or "reject the Null Hypothesis" was reinforced only in the presence of "effect matches hypothesis prediction" and "low p value". For any other combination of sample and contextual stimulus, selection of "not consistent with Scientific Hypothesis" or "fail to reject the Null Hypothesis" was reinforced. The second and third panels of Figure 19.12 illustrate the test trials used to evaluate the transfer of contextual control to the B and C stimuli.

All 10 students demonstrated the ABC and DEF equivalence classes made possible by Lessons 1 and 2, as well as the relations trained under contextual control in Lesson 3, improving from moderate pretest scores at best to perfect or near-perfect scores in the posttest. Nine of the 10 students also demonstrated high percentages of emergent contextual control by the B and C stimuli. Figure 19.13 presents scores for each student on the two contextual transfer tests (illustrated in Figure 19.11) for all trials (left panels) and for those trials that required control by Lesson 3 (right panels). In this demonstration, then, many sophisticated performances emerged (4.7 times more than the number of relations directly taught) after approximately 45 minutes of training time. What's more, these emergent performances reflected an understanding of the interrelations that define basic statistical reasoning, even in the absence of instructor explanations—an

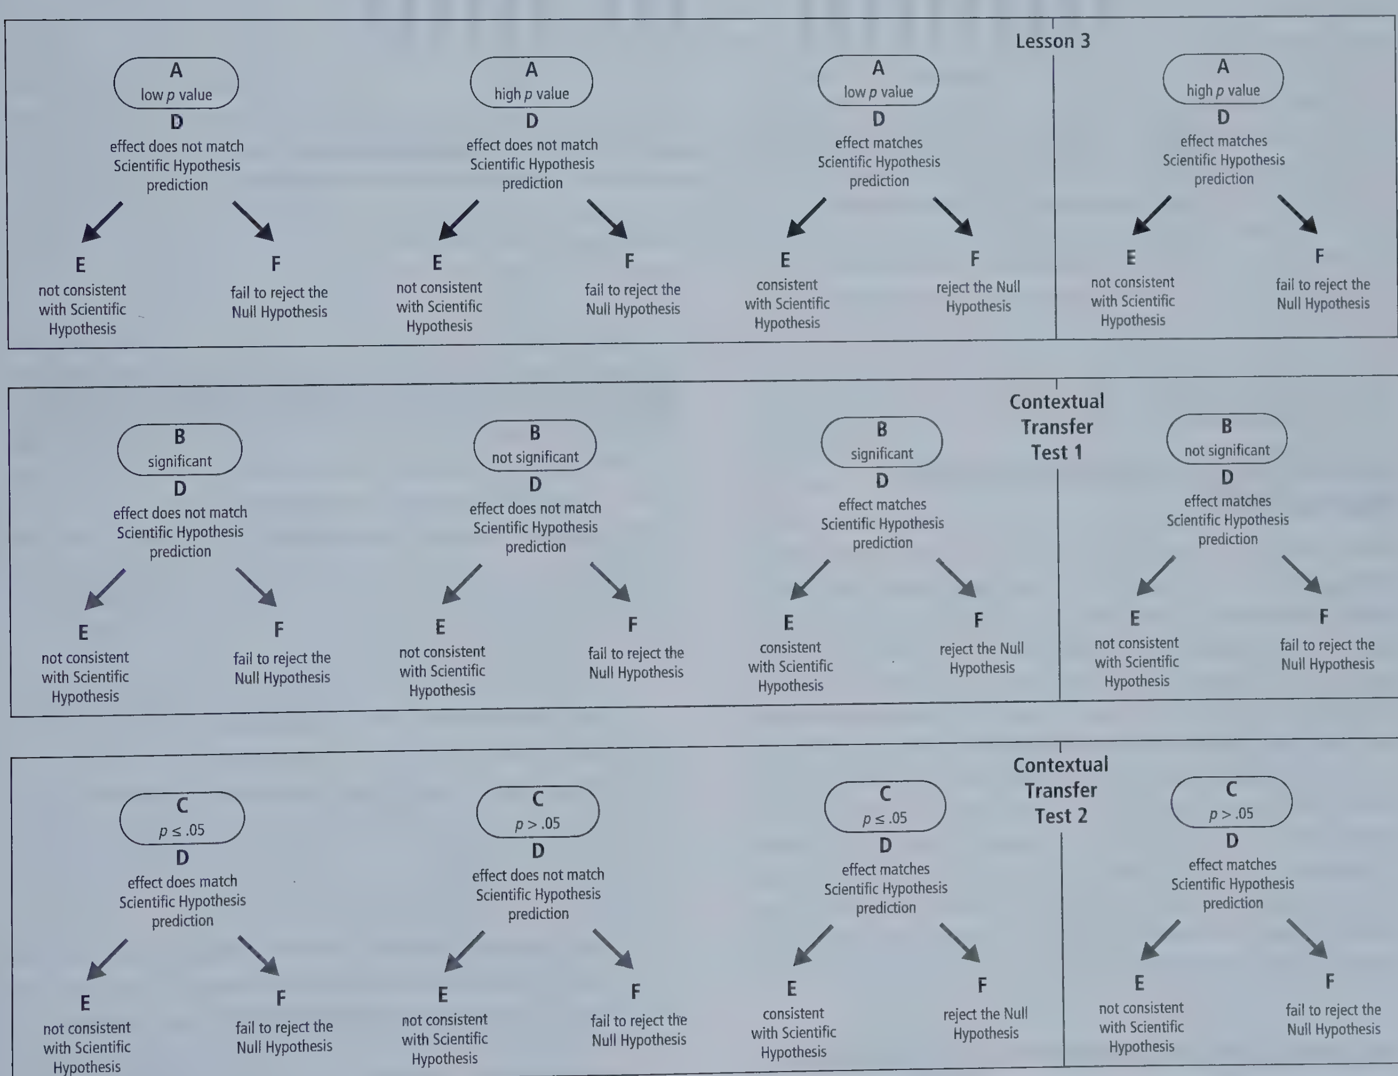

Figure 19.12 Schematic representation of trained contextual control relations from Lesson 3 (top panel) and contextual control tests (middle and bottom panels), with trained relations indicated by black arrows and tested relations indicated by gray arrows. Note that the tested contextual stimuli were never part of contextual control training, but were part of equivalence classes established in Lesson 1.

impressive illustration of the generativity and nuance made possible with contextual control.

DESIGNING EQUIVALENCE-BASED INSTRUCTION

Equivalence outcomes are impressive, but they do not happen by magic. Research has shown a number of training and testing variables to be important for the successful generation of equivalence classes, whether in the laboratory or in the field. To illustrate these variables, this section of the chapter describes a series of decisions that need to be made in planning effective procedures for EBI, presented in the order in which they would be implemented. In point of fact, the equivalence outcome is quite robust, having been demonstrated with a wide variety of procedural variations, so there is no single route to strong EBI design. A number of problems can be avoided with careful design, however, and the discussion that follows will highlight some of these potential complications. Table 19.1 outlines the major design decisions that guide the planning for EBI training and testing.

TABLE 19.1 Equivalence-based Instruction Design Decisions

I. *Training Considerations*
   A. What stimuli will be used and how many?
   B. How will the stimuli be presented?
   C. Will a sample- or comparison-observing response be required?
   D. What instructions will be given?
   E. How will balanced trial arrangements be ensured?
   F. Are special training steps needed?
   G. What training structure will be used?
   H. What mastery (accuracy) criteria will be used for training?
   I. How will consequences be scheduled during training?

II. *Testing Considerations*
   A. How will the probe trials be presented?
   B. How will consequences be scheduled?
   C. How will the probe-trial types be ordered?
   D. What will be the criteria for equivalence-class formation?

Training Baseline Conditional Discriminations

The most common approach to generating equivalence classes involves teaching a minimum of two interrelated conditional discriminations with the matching-to-sample procedure. Arranging these four-term contingencies requires a number of methodological choices, including the selection and presentation of stimuli, observing responses, instructions, trial-type arrangements and sequences, instructional programming, training structure, mastery (accuracy) criteria, and consequence delivery.

Selecting and Presenting Stimuli

A wide range of stimulus types has been used effectively in equivalence research. In laboratory studies where the emphasis is on experimental control, unfamiliar line drawings (e.g., Dougher et al., 1994), abstract figures or objects (e.g., Pilgrim & Galizio, 1990), letters from a foreign alphabet (e.g., Sidman & Tailby, 1982), or meaningless nonsense syllables are common (e.g., Fields, Hobbie, Adams, & Reeve, 1999), to rule out the possibility that performances demonstrated on probe trials are due to experience with the stimuli outside the lab. Although auditory and visual stimuli are probably the most convenient options, many different stimulus modalities have been represented as equivalence-class members, including tactile stimuli (hidden objects contacted only by touch; e.g., Bush, 1993), odors (e.g., Annett & Leslie, 1995), tastes (e.g., Hayes, Tilley, & Hayes, 1988), and drug effects (DeGrandpre, Bickel, & Higgins, 1992). In applications of EBI, the choice of stimuli will necessarily depend on the nature of the skills being targeted.

Again, the options are virtually limitless. Early language training programs might include objects or pictures, spoken words, and written words, as illustrated in Sidman's early work (Sidman, 1971; Sidman & Cresson, 1973), in either native or non-native languages (e.g., Joyce, Joyce, & Wellington, 1993), while programs designed to establish basic math skills might include quantities of objects, numerals, and spoken number names, or fractions, decimals, and pictorial representations of fractions (e.g., Lynch & Cuvo, 1995). In other illustrations, Braille letters, printed letters, and spoken letter names became equivalence-class members for children with degenerative visual disorders (e.g., Toussaint & Tiger, 2010); the photographs, office name-plates, and spoken names of therapists became equivalent for adults with brain damage (Cowley, Green, & Braunling-McMorrow, 1992); and for college students, the name of brain lobes, specific lobe functions, and brain diagrams became interchangeable class members (Fienup, Covey, & Critchfield, 2010). Applied research with stimulus sets such as these typically incorporate control procedures to rule out extra-experimental learning with the stimuli as responsible for probe performances. Strategies include pretests with each possible stimulus relation, testing all possible stimulus relations before and after teaching each of a series of subsets of the stimuli, and simultaneous multiple-baseline designs.

Another important decision in conducting equivalence work involves the number of stimuli to use. Once again, the best answer here will depend on the participant population and the instructional goals. A number of variations are represented in the literature, but in many cases a reasonable starting point for teaching a first conditional discrimination is to present three different sample stimuli (i.e., A1, A2, and A3) across trials with three different comparison stimuli (i.e., B1, B2, and B3) on each trial. At first glance, beginning with three stimuli for each set may seem counterintuitive—why not start more simply, with just one or two samples and comparisons? The issue is that doing so can allow for the inadvertent reinforcement of stimulus-control patterns that conflict with those being targeted by the training. Consider a case in which sample A1 and comparisons B1 and B2 are presented on every trial for a block of 20 trials, and selection of B1 produces a reinforcer on each trial. A participant might learn quickly to select B1, but doing so would require only a simple discrimination between the two comparisons. Sample A1 has no necessary role in determining the appropriate comparison selection under these conditions, as B1 is always correct. Not only is establishing control by A1 over selection of B1 unlikely here, but control by sample stimuli more generally (e.g., as in control over the participant's attending or observing) could be decreased as well, leaving conditional discrimination more difficult to achieve in subsequent teaching steps.

Next, consider a case in which two sample stimuli (e.g., A1 and A2) alternate irregularly across trials in a block with two comparison stimuli (e.g., B1 and B2) presented on every trial. Now control by the sample is necessary to produce a reinforcer on each trial (that is, selecting B1 is reinforced only in the presence of sample A1, and selecting B2 is reinforced only in the presence of sample A2). In this case, however, it is possible for correct selections to be made, and thus reinforced, in either of two ways. With A1 as the sample, for example, a child could learn to either *select* B1 (known as *Type S* or *select responding*) or to *reject* B2 (known as *Type R* or *Reject responding*) and simply choose whatever else is available. In the first case, the reinforced relation is between sample A1 and comparison B1; in the second case, the reinforced relation is between sample A1 and comparison B2—two different forms of stimulus control (also described as different **stimulus-control topographies**; Dube & McIlvane, 1996; McIlvane & Dube, 2003). The first form of stimulus control would be consistent with the teacher's goal; that is, *stimulus-control topography coherence* would hold between the teacher's target and the child's behavior. If only the second form of stimulus control was established, a lack of coherence would be present, and any resultant equivalence classes would necessarily differ from those targeted by the teacher as well (e.g., A1 and B2 could be members of the same class; see, for example, Carrigan & Sidman, 1992). Using more than two comparison stimuli decreases the likelihood of exclusive Type R control, because the number of reject relations required to produce reinforcement on any given trial increases with each comparison added to the array. For example, given A1 as sample, both comparisons B2 and B3 would need to be rejected from a three-choice array, while only a single Type S relation (e.g., A1B1) is required to produce reinforcers (e.g., Sidman, 1987). In certain circumstances, limiting comparisons to only two or presenting only a single sample stimulus for a series of trials may be appropriate, but the teacher will then need to be watchful for evidence of conflicting stimulus control, and additional training steps may be necessary to ensure a shift in stimulus control.

Given these issues, it follows that presenting at least three comparison stimuli per trial is generally recommended. As a complete demonstration of all three properties of equivalence (i.e., reflexivity, symmetry, and transitivity) requires a minimum of two interrelated conditional discriminations (e.g., AB and AC) with at least three stimulus sets (e.g., A, B, and C stimuli), a total of nine different stimuli would be necessary as a starting point. From there, the number of stimuli per set can be increased as appropriate to the task at hand (e.g., remember that Sidman's first studies used stimulus sets of 20 each, for a

total of 60 stimuli), and as we have seen, the number of sets can be increased as well.

Equivalence-based instruction is also flexible with respect to the mode of stimulus presentation. Modern technology makes computerized matching-to-sample procedures relatively straightforward to design and implement; both the basic laboratory and applied literatures are replete with examples (e.g., see Green & Saunders, 1998; Saunders & Williams, 1998). The sample stimulus is typically presented either at the top of the computer screen or in a center position, with the comparisons presented either in a horizontal row below the sample or in the corners of the screen. The participant's responses (typically mouse clicks, key presses, or touches) are recorded automatically, with auditory and/or visual consequences programmed to follow immediately. Computer presentations have the advantage of ensuring procedural integrity, as all teaching and testing parameters are pre-programmed and consistently applied. Indeed, the promise of developing computerized equivalence-based teaching programs for specific targets in educational settings (e.g., reading, spelling, coin equivalences) has been long noted (e.g., Sidman, 1994), freeing teacher time from basic lessons to more individualized instruction. To say that current application platforms and Internet technologies have significantly enhanced this potential would be an understatement (see, for example, Barron, Leslie, & Smyth, 2018).

Sophisticated computer programming is hardly necessary for equivalence approaches, however, and many elegant examples of "table-top procedures" have been utilized effectively. For example, stimuli have been presented manually in a Wisconsin General Testing Apparatus (Harlow, 1949), where the experimenter and participant sit on opposite sides of a wooden partition. Raising a door at the base of the partition allows a tray holding stimulus objects to be presented to the participant. For example, the sample stimulus might be positioned at the top of the tray, with three comparison stimuli arranged in a row at the bottom of the tray. A concave well below each stimulus object allows a reinforcer (e.g., a small edible, a penny, or a token) to be hidden, so that removing the appropriate comparison provides access to the reinforcer (e.g., Pilgrim, Chambers, & Galizio, 1995). Similar strategies have included a large teddy bear or cloth screen used in place of a wooden partition to block any potential experimenter cuing, with stimulus cards arranged in a systematic format in front of the participant (e.g., Horne, Lowe, & Randle, 2004). In other arrangements, sample and comparison stimuli have been presented as pictures on a page of a three-ring binder or notebook (e.g., with a sample picture at the top of the page and comparison stimuli in a row at the bottom), where each page presents a new trial, or even more simply, by arranging individual objects or cards with stimulus pictures in a set configuration on a table in front of the participant. This flexibility in stimulus-presentation modality is important in allowing the EBI approach to be adapted to the particular needs of a given setting or participant. At the same time, table-top procedures carry the extra burden of requiring appropriate controls to prevent experimenter or teacher cuing (which could lead to false conclusions about emergent performance), and to ensure procedural integrity (the absence of which can dramatically decrease the effectiveness of teaching and testing methods). Tactics such as having the teacher always sit or stand behind the participant, and incorporating interobserver reliability measures, are common with these arrangements, for example.

Observing Responses

Control by the sample stimulus is critical to the acquisition of conditional discriminations in a matching-to-sample procedure. For this reason, on each matching trial, standard practice is to require the participant to make an *observing response* to the sample stimulus (e.g., a mouse click over the sample stimulus or a touch to the sample) once it is presented. The sample-observing response then results in presentation of the comparison stimuli and the opportunity to access reinforcers. The observing-response requirement is designed to increase the likelihood that the participant will actually notice (i.e., observe) the sample. In cases where sample control proves difficult to establish, requiring a unique response for each sample stimulus has often been effective (e.g., see Saunders & Williams, 1998). For example, a participant might be required to give a different but specific name for samples A1, A2, and A3 (e.g., Saunders & Spradlin, 1993; Pilgrim, Jackson, & Galizio, 2000); alternatively, a different gesture (e.g., a wave, a thumbs up, and a clap) or a different schedule performance (e.g., a fixed ratio [FR] and a differential reinforcement of low rates [DRL] schedule in a two-comparison procedure; Sidman et al., 1982) could be required in the presence of each sample. The advantage of a *differential sample requirement* is that it requires *successive discrimination* between the sample stimuli that are presented on different trials.

Similarly, requiring an observing response to each comparison stimulus prior to a final comparison selection can sometimes prove beneficial, especially if concerns arise about a participant making choices impulsively, without viewing each of the alternatives. For example, touching or naming each comparison in the array prior to the selection response should increase contact with each of the choices, and thereby increase the likelihood of control by the correct comparison.

Instructions

Task instructions in conditional discrimination training have varied from simple (e.g., "Touch one"; Lynch & Green, 1991) to more detailed (e.g., "Pick the one that matches" or "When you see this [A1], choose this [B1]"; Pilgrim, Jackson, & Galizio, 2000; Saunders, Saunders, Kirby, & Spradlin, 1988), and the best instruction set will again necessarily depend on instructional goals and the participants involved. For basic laboratory research in which the experimental question focuses on the role of the reinforcement contingency in generating equivalence, adding instructional control to the mix will complicate the analysis. Conversely, when producing an applied outcome is the sole focus and the isolation of controlling variables is a less important issue, a combination of instructions or other prompts and reinforcement contingencies can enhance acquisition of the conditional relations necessary to give rise to emergent performance. With some populations, such as young children or individuals with intellectual disabilities, reinforcement contingencies alone, in the absence of other programming, can be insufficient for establishing arbitrary conditional discriminations (e.g., Pilgrim, Jackson, & Galizio, 2000; Augustson & Dougher, 1992). As

long as the teacher ensures that the trained conditional discriminations are maintained once instructional prompts are removed, the groundwork is laid for equivalence outcomes.

Arranging Trial Types and Sequences

Careful attention to the balanced composition of trial types, as well as the order in which those trial types are presented within a block of trials, is essential to preventing a number of forms of competing stimulus control from interfering with conditional discrimination acquisition. Several standard practices have been developed specifically to guard against such issues. Let's say that we want to teach an AB conditional discrimination, such that comparison stimuli B1, B2, and B3 are selected in the presence of sample stimuli A1, A2, and A3, respectively. Three different trial types would be needed, one with each of the sample stimuli; the same three comparisons would be presented as choices with each sample. These three trial types should be presented the same number of times within a training trial block, to ensure an equal opportunity for reinforcement with each comparison. Imbalance here could create a bias toward selecting one (or more) comparison(s) over the others. Further, the position of the comparison stimuli should be counterbalanced across trials, such that each stimulus appears in each possible position on an equal number of trials. Imbalance here could result in a conditional relation between the sample stimulus and a particular position, rather than a particular comparison. Similarly, the position of the correct or S+ comparison stimulus should be counterbalanced across trials, such that the reinforced choice appears in each position on an equal number of trials. Failure to do so could again result in a preference for one stimulus location over the others. Finally, we would typically set a limit on the number of consecutive trials allowed within a block (e.g., no more than two or three trials in a row) (1) with the same sample stimulus, so that control by the sample is ensured, and (2) with the S+ comparison in the same position, so that responding to a particular position will not be inadvertently strengthened. With these constraints met, the order of trials within a block should otherwise vary unsystematically. To illustrate, the top half of Table 19.2 presents nine trials balanced with respect to the number of each trial type and the position of each comparison stimulus, including the reinforced or S+ choice. The bottom panel of Table 19.2 shows the same trials in a semi-randomized order that could prevent inadvertent reinforcement of sequences of stimulus or position selections. Consecutive trial blocks and/or teaching sessions should also use a newly randomized sequence of trials (maintaining the same constraints) so that a simple chain of responses cannot be established.

In sum, planning these details of trial arrangements prior to their presentation will help to ensure stimulus-control topography coherence—in this case, conditional control by the sample stimuli over specific comparison selections. Optimally, the number of trials presented in a trial block should be sufficient to allow for balance along each of the dimensions outlined above, while the number of trials or trial blocks to be completed within a single session will necessarily depend on the participant population. For example, young children may lose interest in the task after a relatively limited number of trials, so blocks ranging from 9 to 27 trials are common, while college students will often

work for periods of 1 to 3 hours and completion of many trial blocks is possible.

Instructional Programming

As noted above, for some participants or participant populations, teaching techniques in addition to the matching-to-sample reinforcement contingencies are necessary to produce mastery of the baseline arbitrary conditional discriminations. Verbal instructions have already been mentioned; other enhancements have included various prompting procedures, modeling the correct choices (e.g., Michael & Bernstein, 1991), and correction procedures, whereby a given trial is repeated until a correct choice is made (e.g., see Green & Saunders, 1998), for example. Some approaches have incorporated a systematic introduction of specific training-trial types designed to target particular dimensions of conditional control, in order to facilitate acquisition of the required baseline relations; these include teaching the component simple discriminations, stimulus-control shaping, exclusion training, and programmed introduction of the multiple conditional discriminations.

Teaching the Component Simple Discriminations. This training approach is based on the recognition that accurate conditional discrimination performances require two different types of simple discriminations, in addition to conditional control by the sample (e.g., Carter & Eckerman, 1975). These include *successive discrimination* between the sample stimuli, which are presented sequentially across trials, and *simultaneous discrimination* between the comparison stimuli, which are presented together as the choice array on a given trial. While the former often proves more challenging than the latter (e.g., Carter & Eckerman, 1975), assuming either can be problematic, particularly with young children or individuals with intellectual disabilities, and the absence of either will necessarily result in failure on the conditional discrimination task.

One teaching sequence designed to ensure all of the necessary component discriminations introduces a series of pretraining steps. Simple simultaneous discrimination is taught first with the stimuli that will serve as comparisons (e.g., B1, B2, and B3). Each stimulus serves as the S+ (that is, selection of that stimulus is reinforced) across phases (e.g., selecting B1, then B2, and then B3 is reinforced), and a new phase begins only after reliable selection of the S+ has been demonstrated (Saunders & Spradlin, 1993). In the second pretraining step, the stimuli that will eventually serve as samples (e.g., A1, A2, and A3) are presented individually, one at a time, over a series of trials, and a different response (e.g., naming, patterns of button pressing) is shaped and reinforced in the presence of each until this discriminative performance is strong (e.g., Saunders & Spradlin, 1989, 1993). In the third step, conditional discrimination trials are presented for the first time in blocks, such that sample A1 is presented for some number of trials in a row with B1, B2, and B3 as comparisons. A block of trials with sample A2, and then with A3, follows, with the same comparisons and for the same number of trials. The differential sample responses are still required, and the number of trials in a block is gradually decreased until the trial types with A1, A2, and A3 as sample are thoroughly intermixed. In this way, control by the sample stimulus alone becomes increasingly necessary. At this point, the procedure is a standard arbitrary matching-to-sample arrangement with accurate conditional responding established step by step.

Stimulus-control Shaping. Two approaches in this category resemble fading or errorless discrimination procedures by first teaching an easily acquired discrimination and then shifting gradually to a more difficult arbitrary conditional discrimination. In both cases, identity matching-to-sample serves as the starting point. Zygmont, Lazar, Dube, and McIlvane (1992) demonstrated the effectiveness of *stimulus-control shaping* with two 4- to 6-year-old typically developing children and two individuals with moderate to severe intellectual disabilities, none of whom had been successful in arbitrary match-to-sample training. The shaping programs began by first establishing identity matching with two abstract black-and-white-line drawings as sample and comparison stimuli; trials with each sample alternated here and throughout all training steps. Next, in Phase 1, the shape of one sample stimulus was modified in small increments across a series of training steps, while maintaining selection of the appropriate comparison. Figure 19.14 denotes the initial training stimuli as Step B for baseline, and shows that the sample and S+ (that is, the correct comparison) were physically identical at baseline; the subsequent rows of the figure illustrate the sequence of changes that were made to the sample drawing across training steps. When the target shape was achieved for Sample 1 (in Step 9, labeled FP for Final Performance), Phase 2 presented a similar training series for Sample 2, with gradual alterations made to its shape across steps. By the end of training, all four participants demonstrated accurate arbitrary conditional discrimination performance involving physically distinct samples and comparisons. Although the stimuli involved in this translational study were abstract line drawings, the shaping strategy could be easily applied to a wide range of teaching materials.

A second approach also shaped arbitrary sample control across a series of phases. To start, accurate identity matching (Pilgrim, Jackson, & Galizio, 2000) was established with young, typically developing children, first with pictures of familiar everyday objects (e.g., a pencil, a flower, and a boy's face), and then with abstract line drawings, indicating conditional control by sample stimuli across a range of stimulus types. The next training phase presented a *thematic matching* task in which the sample and correct comparison stimulus were physically dissimilar, but members of a common category or theme presumed to be familiar to the children. For example, with a picture of an ice cream cone as sample, selecting a picture of a birthday cake instead of a car or a bird was reinforced. Accurate performance on this training step extended conditional control to stimuli that had no physical resemblance to the correct comparison. When an arbitrary matching task with unfamiliar line drawings was presented next, the conditional discrimination was learned quickly, both by children who had failed to master the task previously and by experimentally naive children taught with this sequence from the start (Pilgrim et al., 2000).

Exclusion Training. This approach to teaching a new arbitrary conditional discrimination is based on a robust outcome known as **exclusion**, in which a novel comparison stimulus will be

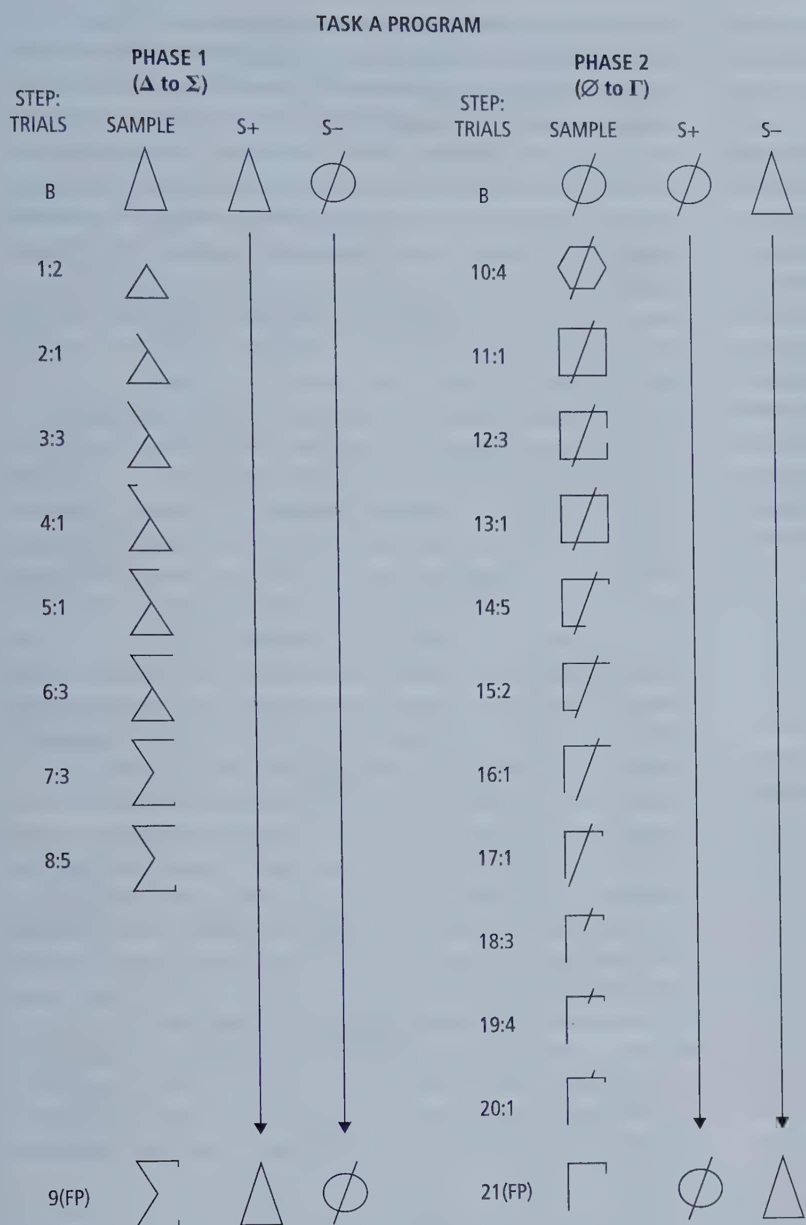

Figure 19.14 Steps of stimulus control shaping. Identity matching at baseline (B) was gradually changed to arbitrary matching by modifying the form of the sample stimulus in a series of steps, first for one sample (shown on the left side of the figure) and then for the other (shown on the right side of the figure).

selected over a known one in the presence of a novel sample (e.g., de Rose, de Sousa, & Hanna, 1996; McIlvane & Stoddard, 1981). Let's say, for example, that the starting repertoire of a young child with autism includes selecting the appropriate picture of a bird, a dog, and a cat when she hears the corresponding spoken word, but that matching printed letters of the alphabet to their spoken names occurs at chance levels of accuracy. A teacher might then present the spoken words "bird," "dog," and "C" as samples, with pictures of a bird, a dog, and the printed letter C as comparison choices. The exclusion effect would be demonstrated by the child's selecting the printed letter when presented with "C" as the sample, which would be followed by a reinforcer. Selecting other letters (e.g., B and D) in the presence of their spoken names could be established in similar fashion. Thus, by carefully intermixing new sample-comparison combinations with familiar stimulus relations, teachers can repeatedly create the opportunity for reinforcing target comparison selections in the presence of target sample stimuli. Although the name implies that the "known" comparison stimulus is excluded (a form of Type R or Reject relation), studies have consistently demonstrated that once demonstrated through exclusion, conditional control by the sample is maintained when the new relation is presented together with other samples and comparisons from the training set (rather than the already familiar combinations); that is, Type S or Select control is demonstrated. For example, a later training step following from our example above might present the three letter names as samples with the three printed letters as comparison choices. In this way, exclusion programming can be utilized to build the new arbitrary conditional discriminations required as baseline performances for equivalence outcomes.

Sequential Versus Simultaneous Introduction of Multiple Conditional Discriminations. The previous sections have focused on teaching a single conditional discrimination but, as described earlier, two (or more) conditional discriminations

(e.g., AB and AC) are necessary to allow for all defining tests of equivalence-class formation. Any of the teaching strategies outlined above could be applied in training additional conditional discriminations, of course, but fortunately, this is often unnecessary; establishing a first arbitrary relation frequently allows for rapid acquisition of those taught later (e.g., Pilgrim et al., 2000), an example of a learning-set outcome (Harlow, 1949). When children or individuals with intellectual challenges receive EBI, standard practice is to teach each conditional discrimination independently (e.g., AB training followed by AC training), and then to intermix the trial types making up each set of relations within a single trial block. A next conditional discrimination (e.g., AD) could then be trained in isolation, subsequently added to a mix of trials from all three, and so on, such that the baseline from which equivalence classes could emerge is developed sequentially. The alternative—introducing the mix of trial types from multiple conditional discriminations from the start of training—can sometimes save training time for select participant groups, such as college students.

Training Structures

Whether approached sequentially or simultaneously, teaching multiple conditional discriminations necessarily requires decisions about the specific sample-comparison combinations that will make up each conditional discrimination, and about the manner in which the different conditional discriminations will be interrelated. These dimensions of the teaching arrangement are described generally as the **training structure**. At least one stimulus set, often referred to as the **nodal stimulus** set or, more simply, the **node**, must be held in common across a minimum of two conditional discriminations to provide a basis for all equivalence properties. A number of different training structures are well represented in the experimental and applied literature on equivalence. For example, in Sidman's early studies reviewed in detail above, AB and AC conditional discriminations were trained. This arrangement is known as *one-to-many training*, in that one set of sample stimuli (e.g., the A stimuli in this case) is trained with multiple sets of comparison stimuli (e.g., B and C, in this example). A synonymous term for this training structure is *sample-as-node training*, which emphasizes that the A stimulus set serves a sample function in both of the trained conditional discriminations and thus provides the basis for emergent relations between stimuli from the different conditional discriminations (e.g., between B and C stimuli, in this case). A second popular training protocol is the *many-to-one* or *comparison-as-node* structure. In this arrangement, multiple sets of sample stimuli are trained with a single set of comparisons, and the comparison stimuli thus serve as node. For example, AB and CB conditional discriminations could be trained such that the B comparison stimulus set is held in common. A third structure is known as a *linear series training*. Here, the comparison stimuli from one conditional discrimination serve as sample stimuli in the next; for example, AB and BC relations might be taught. Each of these training structures could be applied with more than two conditional discriminations as well (e.g., AB, AC, and AD for one-to-many training; AB, CB, and DB for many-to-one training; AB, BC, and CD for linear series training, where two different nodes would be involved). Figure 19.15 illustrates these common training structures with a single stimulus from each of four sets (A to D). A total of three conditional discriminations are represented for each training structure, and the arrows in this diagram always point from a sample stimulus to the comparison selection that would be reinforced on a given training trial. In each case, teaching the matching performances shown by the arrows would serve as the baseline for emergent matching between any of the stimulus pairs not linked by an arrow. Finally, many examples of EBI have utilized mixed training structures with multiple nodal stimuli (e.g., AB, AC, and DC training); the variations in this category are extensive.

A number of studies have compared the effectiveness of these training structures for teaching the baseline conditional discriminations and for generating equivalence outcomes (e.g., Arntzen, 2012; Saunders, Saunders, Williams, & Spradlin, 1993). There are some reports of faster baseline acquisition with one-to-many training, perhaps because the more challenging successive discriminations between sample stimuli are required for only one set of stimuli (see Saunders & Green, 1999, for analysis), but these findings have not always been replicated. Similarly, across studies, one-to-many and many-to-one training structures appear to be equally effective for producing equivalence performance, with some studies favoring one-to-many slightly (e.g., Arntzen & Holth, 1997) and others favoring many-to-one (e.g., Fields et al., 1999). Certainly both provide a strong basis from which equivalence classes can be demonstrated. The one training structure that has consistently underperformed, compared to the others, in generating equivalence is linear series training (e.g., Arntzen, 2012), particularly as the number of trained conditional discriminations increases. Although linear series training has proved effective with many participants, this training arrangement is probably best avoided unless needed for other experimental reasons (e.g., to avoid a ceiling effect for equivalence successes, so that the impact of other procedural variables can be better analyzed). Either of the other structures

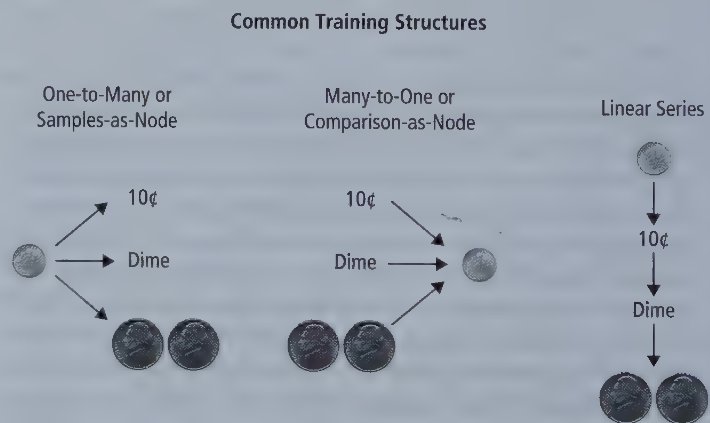

Figure 19.15 A schematic representation of three different training structures. Three conditional discriminations are represented for each structure, by presenting one stimulus from each of four sets (A, B, C, and D). The one-to-many (or sample-as-node) structure is presented in the left column, the many-to-one (or comparison-as-node) structure in the middle, and the linear series structure on the right.

can be a good choice for EBI, and the best selection will depend on factors such as the type of stimuli to be used (e.g., auditory stimuli are difficult to present as comparisons in the absence of special procedures) and the instructional goals of the EBI program.

Mastery (Accuracy) Criteria

The trained conditional discriminations provide the necessary prerequisites for equivalence-class formation, so it is essential that performance on all trial types is strong and consistent. To ensure this end, EBI programs incorporate predetermined *accuracy or mastery criteria* that must be met in each phase of training before moving on to the next. Typically, overall accuracy is measured for each trial block and defined as the number of trials on which the S+ comparison is chosen divided by the total number of trials in the block. (When acquisition is problematic, separate accuracy measures for specific trial types—e.g., all trials with each sample stimulus—are important to analyze as well.) Because intermediate accuracy scores (e.g., 75%) can reflect multiple sources of stimulus control (e.g., see Sidman, 1980, 1987), the mastery criteria are typically set at a relatively high accuracy percentage and are often required for more than one consecutive trial block (unless the number of trials composing the block is large). For example, in one series of studies (Pilgrim & Galizio, 1990; Pilgrim, Chambers, & Galizio, 1995), adults and children received conditional discrimination training in trial blocks consisting of 16 trials each. The mastery criteria for each training phase required accuracy of at least 88% (14 out of 16 trials correct per block), with no more than one error on any given trial type, for two consecutive sessions.

Scheduling Consequences During Training

Match-to-sample training for one or more conditional discriminations will typically include reinforcers for selection of the S+ comparison on every trial until the specified mastery criteria are met. Choosing an appropriate and effective reinforcer for EBI training is subject to the same considerations that would hold for any applied behavior analysis program. Common examples have included points or tokens worth money or prizes, small edibles, written feedback (e.g., "Correct" or "Incorrect"), attractive visual displays or cartoons, and auditory jingles or chimes. Some teaching programs also include mild punishers (e.g., a brief buzzer, a short time-out, or a trial repetition) for S− selections, again programmed for every training trial until mastery is achieved. Before moving immediately from continuous reinforcement to tests for the properties of equivalence, however, a common practice is to first arrange intermittent reinforcement, where the number of trials per block that include programmed consequences is decreased, often in a series of steps, with mastery criteria required at each step. For example, the steps might include having reinforcers available on 100%, then 75%, and then 50% of the trials. At issue in these reinforcement reductions is preparation for the introduction of the test or *probe trials* designed to evaluate equivalence-class formation. Probe trials are typically presented in extinction, to allow for interpretations of emergent versus directly trained relations. Without adequate preparation, the absence of reinforcers for novel probe performances can produce variability in comparison selections, whereas training to mastery with intermittent reinforcement helps to ensure response maintenance in the absence of trial-by-trial consequences. Relatedly, one benefit of including punishers as part of the training contingency is that doing so provides a basis for discrimination between incorrect responses and the mere absence of a reinforcer.

Some EBI programs have included final training steps with still leaner schedules, arranging programmed consequences for only 20% or even 0% of the trials (e.g., Sidman & Tailby, 1982). Although motivation can become an issue, experience with lean reinforcement schedules for trained relations makes discrimination between training trials and later probe trials less likely, with the net result that probe responding is not differentially extinguished. Strategies designed to counteract the low reinforcer density have included providing alternative bases for reinforcement (e.g., color-matching trials presented at the end of the AB and AC training block; e.g., Sidman & Tailby, 1982) and/or instructions (e.g., "In this part of the game, I can't tell you whether you are right or not, but you should continue to do your best."). As usual, the appropriateness of such strategies will depend on the participant population and the reasons for conducting the EBI program.

Testing Protocols

As was the case for baseline training, a number of different testing procedures are reflected in the equivalence literature. Many decisions about testing arrangements carry important advantages and disadvantages, such that careful consideration is warranted for procedural details, including the presentation and order of probe trials, consequence scheduling, and criteria for equivalence-class formation.

Composition of Probe-trial Blocks

Two general methods are used for presenting probe trials: *massed testing* and *interspersing* probe trials with baseline-trial types. In the first method, the trial block is composed of probe trials only. In the second, the block includes probe trials as well as each of the baseline training trial types presented in a semi-randomized order, often with no more than one or two probe trials presented in succession. Massed testing allows for more rapid assessment of equivalence-class formation, but when equivalence outcomes are not demonstrated, this approach leaves open the question of whether the prerequisite baseline relations have been maintained. Introducing novel trial types in discrimination studies can sometimes disrupt previously mastered performances, at least temporarily, and this issue may be particularly relevant with some participant populations. If the trained conditional discriminations are not strong, there is no reason to expect equivalence to emerge, and in the absence of baseline-trial types, this possibility can be neither evaluated nor remedied. Related strategies have included beginning test sessions with a baseline-review trial block (e.g., Kennedy, Itkonen, & Lindquist, 1994) or alternating baseline-review and massed-probe trial blocks. These arrangements necessarily mean that the equivalence assessment is less rapid and actually represents approximations of the interspersed trial-type approach. In any case, some provision for evaluating the

maintenance of baseline performances is critical in those cases in which equivalence outcomes are not demonstrated. When interspersed, the proportion of probe trials to baseline trials varies considerably across EBI programs and is often determined by the overall reinforcement density being targeted (i.e., with no reinforcers for any probe trial, and intermittent reinforcement for the baseline trials) and the necessary balanced composition of trial types described for training arrangements. To illustrate, Table 19.3 presents a balanced trial block composed of three symmetry probes and nine baseline training trials.

Scheduling Consequences During Testing

When baseline-trial types have been included as part of the test sessions, decisions must be made about scheduling consequences for those trials. In some EBI programs, consequences are programmed for at least a portion of the baseline trials (e.g., Sidman et al., 1985), such that the trained relations are not only evaluated but also possibly strengthened during testing, and overall task motivation is facilitated. In other work, extinction conditions are in effect for all trial types—baselines as well as probes (e.g., Bush et al., 1989). The latter arrangement is often preceded by instructions, as described previously for leaning the reinforcement density during training (e.g., "You will no longer receive feedback on your selections, but there is still a correct answer, and you should continue to do your best;" e.g., Dougher et al., 1994), although the effectiveness of this strategy will be limited with participants who have poor verbal skills. An advantage of testing in complete extinction is that at least one basis for discrimination between baseline- and probe-trial types is removed, and the possibility that probe trials will be treated differentially (e.g., attended to less carefully) is thereby lessened.

There is also the issue of programming consequences for probe trials. Certainly, the overwhelming majority of equivalence-based instruction, basic or applied, has presented all probe trials under extinction conditions, because a primary research question involves the extent to which new or emergent performances result from the experimental training. In an alternative strategy, however, reinforcers are arranged for probe responses consistent with equivalence-class formation (e.g., Kastak, Schusterman, & Kastak, 2001). In these cases, data analysis is focused on comparison selections for the first presentation of each probe-trial type. Because direct reinforcement cannot yet be responsible for these responses, conclusions about emergent equivalence are still possible. Further, when EBI is implemented for purely practical reasons—for example, to establish an important functional skill for the first time—answering the research question noted above may be less important than ensuring optimal conditions for the acquisition of that skill (e.g., Sidman, 1981), and these will surely include reinforcement of the skill when it is demonstrated, for whatever reason.

Test Order

Whether probe trials are massed or interspersed with baseline trials, one common practice in EBI is to present only one probe type (i.e., reflexivity, symmetry, transitivity and/or combined equivalence) per test-trial block. This practice can allow for multiple presentations of each probe combination within a test block, and it simplifies data analysis. As with the other procedural variables discussed in this section, however, the literature reveals great variety in the order of presentation of the probe types. Indeed, the range of test approaches has run the gamut from introducing the most involved test types first (e.g., after training AB, BC, and CD conditional discriminations, presenting DA tests for combined equivalence as the first probe types; Sidman & Tailby, 1982; Sidman et al., 1985) to beginning with the "simplest" (e.g., testing for BA symmetry first, after AB training combination; Imam, 2006). As we've also seen for the

other procedural variables, the optimal sequence of test presentation will depend largely on the goals of the particular study and the participant population.

For programs of EBI with young children or individuals with intellectual disabilities, where the generation of equivalence classes is of primary interest (as opposed to the factors underlying them), a **simple-to-complex** testing protocol has much to recommend it (e.g., Adams, Fields, & Verhave, 1993). In this arrangement, probe types are introduced sequentially, beginning with symmetry, followed by transitivity (if relevant), and then combined tests for equivalence. Similarly, probe types requiring fewer nodes are presented prior to those requiring more nodes.[4] Further, each probe type is introduced immediately following the minimal training necessary to provide the prerequisites for the probe relation; when probes and baseline trials are interspersed, only those baselines that serve as prerequisites for the probed relation would be included.

For example, consider an EBI program that teaches three conditional discriminations—AB, BC, and CD, as in the linear series training illustrated in Figure 19.15. The simple-to-complex testing protocol for this training is outlined in Table 19.4, and involves the following sequence of training and testing phases: train the AB (coin to price sign) conditional discrimination to mastery; present BA (price sign to coin) symmetry probes interspersed with AB baseline trials; train BC (price sign to written coin name) to mastery; present CB (written coin name to price sign) symmetry tests interspersed with BC baseline trials; train mixed AB and BC; present AC (coin to written coin name) transitivity tests, and then CA (written coin name to coin) combined tests in that order, both interspersed with AB and BC baseline trials; train CD (written coin name to quantity of nickels) to mastery; present DC (quantity of nickels to written coin name) symmetry tests interspersed with CD baseline trials; train mixed BC and CD; present one-node BD (price sign to nickels) transitivity tests and then one-node DB (nickels to price sign) combined tests, both interspersed with BC and CD baseline trials; train mixed AB, BC, and CD; present two-node AD (coin to nickels) transitivity tests and then two-node DA (nickel to coin) combined tests, both interspersed with AB, BC, and CD baseline trials. This approach to systematic increases in test complexity develops experience with each of the necessary simple discriminations as it progresses, and has been shown to increase the likelihood of strong equivalence outcomes (e.g., Adams et al., 1993). For older typically developing children and adults, fewer steps will be necessary, but a testing sequence of symmetry followed by transitivity and combined tests at each nodal level can maximize class formation.

Judging Class Formation

Our earlier section titled "Class Formation" described the basics for assessing this most fundamental EBI outcome. At issue is whether emergent performances indicative of stimulus interchangeability will be demonstrated. Because interpretations of equivalence require reliable class-consistent responding on the defining probe-trial types (e.g., Sidman & Tailby, 1982), data analysis typically focuses on the percentage of probe trials on which comparison selections reflect the equivalence classes that would be expected to follow from the training provided. For example, if teaching signed word to picture (AB) and signed word to written word (AC) conditional discriminations produced equivalence relations, A1B1C1 and A2B2C2 classes would be predicted, with each class including the corresponding signed word, picture, and printed word. For trials presenting a printed-word C1 as sample, then, class-consistent responses would include selections of the matching signed word, picture, or written word (A1, B1, or C1) comparisons on symmetry, combined, and reflexivity tests, respectively. The percentage of class-consistent responses could thus be calculated, either for

TABLE 19.4 A Simple-to-Complex Testing Protocol

all probe trials combined or, especially when class-consistent selections are below 100%, for each probe type individually. When multiple test blocks are presented (versus one massed test presentation, for example), these measures are often graphed and followed across the individual tests. As was the case with judging baseline acquisition, intermediate percentages of class-consistent responses (e.g., 60% to 80%) are indicative of multiple sources of stimulus control (e.g., see Saunders & Williams, 1998; Sidman, 1980, 1987). For this reason, strong conclusions about class formation require relatively high levels of class-consistent responding (e.g., 90% or greater). As with many of our procedural variables, the specific criteria vary across studies, and for purely practical uses, any increase in the probed relations may provide a useful basis for further development.

When the expected emergent performances are not demonstrated immediately, several different strategies have proven helpful. Perhaps the simplest involves repeated presentation of the probe blocks. As noted previously, delayed emergence, in which the probe performances improve with additional testing, is a relatively common finding (e.g., Sidman et al., 1985; Sidman et al., 1986). Delayed emergence has been interpreted as a weakening in competing sources of stimulus control that are not available consistently across probe trials, leaving the equivalence relation as the dominant source of control over comparison selections (e.g., Sidman, 1992, 1994). In addition to repeated testing, low scores on initial probe tests are often improved by re-exposure to the training blocks, especially those that include the baseline prerequisites for the problematic probe types. Other intervention strategies include training or testing modifications that target particular forms of competing stimulus control. For example, if a probe-trial error analysis documents a position preference in which a participant consistently chooses the lower right corner of the computer screen regardless of the stimulus presented, the presentation format could be redesigned so that no stimulus appears in that position on any trial.

Procedural Variations

Teaching a minimum of two conditional discriminations in the match-to-sample format provides the core prerequisites for assessing equivalence-class formation. However, a number of alternative training approaches have been utilized effectively in efforts to (1) explore the range of procedures that might generate equivalence classes; (2) enhance the efficiency of equivalence-based instruction; and (3) enhance the variety of performances that might be produced by EBI. To illustrate, a few of the most prominent of these alternatives are reviewed here, including the use of compound stimuli, class-specific reinforcement, and simple discrimination training.

Compound Stimuli

One procedural variation builds on the matching-to-sample training format by presenting a stimulus compound as the sample. For example, the printed word DOG and a picture of a dog could be presented one above the other as a pair in the sample-stimulus position, and selecting a particular comparison stimulus (e.g., the printed word CANINE) would be reinforced in the presence of that compound. EBI programs utilizing such compounds have revealed that each component of the compound can come to function as an independent equivalence-class member; that is, in the present example, DOG, CANINE, and the dog picture could all be matched interchangeably when presented individually (e.g., Groskreutz, Karsina, Miguel, & Groskreutz, 2010; Lane & Critchfield, 1998). Thus, by using a compound sample, a given amount of training results in many more emergent relations and larger equivalence classes—a finding with important implications for EBI.

In one demonstration of the applied significance of this finding, Stromer and MacKay (1992) used compound stimuli in match-to-sample training designed to target spelling performances in three 9- to 13-year-old boys with academic deficits. Each sample stimulus included a printed word together with a picture (e.g., DOG and a line drawing of a dog). In addition to using compound sample stimuli, the procedure incorporated three additional variations from the standard teaching approach described thus far. First, an *identity match-to-sample* procedure was employed; that is, the S+ comparison stimulus was physically identical to one part of the sample compound. In the present case, on any given trial, the comparison stimuli included either three different pictures, one of which was identical to the picture component of the compound sample, or a group of 10 letters, some combination of which would be identical to the written word component of the sample. The two types of identity trials (i.e., with picture or letter comparisons) were presented equally often in an unpredictable order. Selection of the comparisons that were physically identical to the sample resulted in reinforcement. The second procedural variation involved in this study is known as a *constructed response requirement*. On trials that presented letters as comparisons, the participant's task was to touch, in the correct order, the letters that produced the written word from the sample compound. After the identity matching performances had been taught, a third variation was introduced—a *delayed match-to-sample procedure*. In this step, the compound sample was presented as usual to start each trial; however, an observing response to the compound sample removed it from the computer screen, and the comparison stimuli were presented without the sample being present. Because the comparisons to be presented were unpredictable (i.e., pictures versus letters), this addition required attention to both components of the sample.

The top half of Figure 19.16 illustrates the delay procedure; each column represents a different trial type as it would have appeared on the computer screen. In each case, the compound sample is shown in the top box, and an observing response to the sample produced the display illustrated in the bottom box. Note that the sample stimulus is no longer present in the bottom display, and that the comparisons to choose from include either three pictures for the trial type shown on the left or, for the trial type shown on the right, an array of letters from which the sample word could be composed.

Over the course of the study, this training was arranged with three different sets of printed words (i.e., dog, cat, owl; canine, feline, avian; etc.), one set at a time. The same pictures appeared as part of the sample compound with all printed-word sets; that is, the pictures were held in common across the trained conditional discriminations and thus could serve as nodes. The bottom half of Figure 19.16 illustrates training trials with words from the second and third word set, on the top and bottom rows,

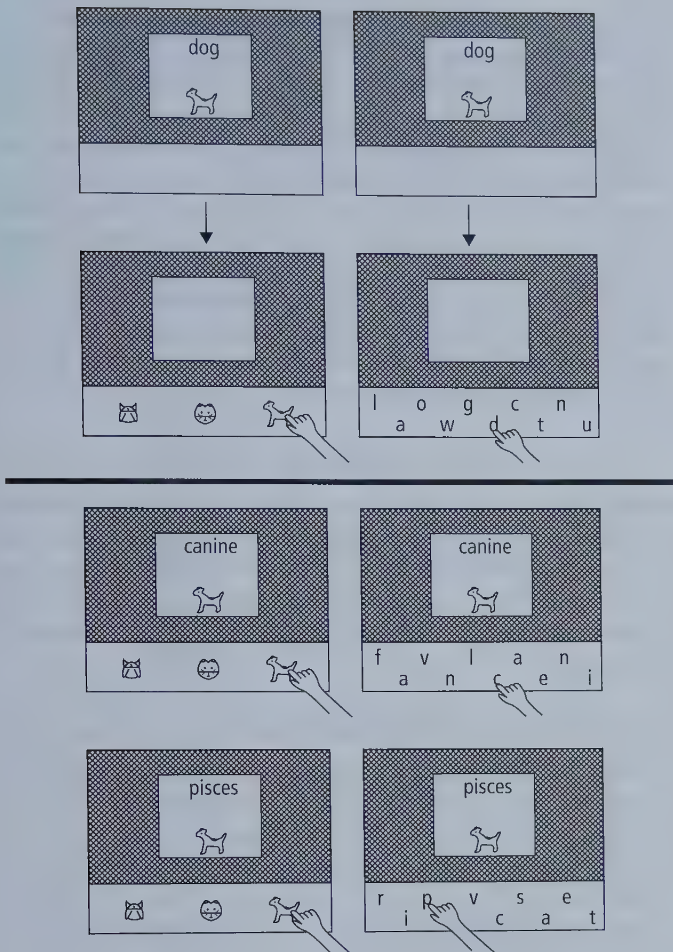

Figure 19.16 The top half of the figure illustrates the delayed matching task. Each column represents a different trial, with the compound sample shown first; an observing response to the sample produced the display in the bottom box. The bottom half of the figure illustrates training trials with words from the second and third word sets. The delay procedure is not represented here but was in place.

Adapted from "Spelling and Emergent Picture-printed Word Relations Established with Delayed Identity Matching to Complex Samples," by R. Stromer and H. A. Mackay, 1992, *Journal of Applied Behavior Analysis*, *25*, p. 898.

respectively; the delay procedure was in place here, too, but is not represented in this figure. Note that in these trial examples, the picture of the dog is common to each sample compound.

Test trials presented each word and picture individually as samples; all possible combinations of the printed words, pictures, and constructed responses were tested after training with each of the three stimulus sets (i.e., a multiple baseline across stimulus sets design). For each test, all three boys demonstrated emergent performances involving only those stimuli for which training had been provided. By the end of training, probe performances revealed the formation of equivalence classes, each of which included a picture, three different printed words, and three different constructed words. That is, any of the visual stimuli within a class could be matched to any other (e.g., DOG and CANINE could be matched) and could occasion any of the three word constructions (e.g., with CANINE as sample, the word DOG could be constructed, depending on the letter choices provided). Further, when the corresponding spoken words were presented as samples on probe trials, any of the three printed words or the picture in the class was selected, and the appropriate spelling was constructed. At this point, the boys had an established spelling repertoire, resulting from EBI.

Class-specific Reinforcement

A second variation on the match-to-sample format involves a particular arrangement of consequences known as *differential outcomes* or **class-specific reinforcement**. In this procedure, not only is the correct comparison choice conditional on the sample stimulus, but the type of consequence delivered is, too. For example, given sample A1, correct selection of comparison B1 would produce Reinforcer 1: a small marshmallow, perhaps. Given sample A2, correct selection of B2 would produce a different reinforcer: Reinforcer 2—let's say, a sip of juice. Teaching a second conditional discrimination would work similarly; for example, selecting comparison C1 given sample A1 would produce the marshmallow, while selecting comparison C2 given sample A2 would produce access to juice. Finally, let's add identity match-to-sample training with D stimuli, such that selecting D1 given a D1 sample produces the marshmallow, with selecting D2 given a D2 sample produces juice.

Several important findings have been obtained with this procedure. Not only can differential outcomes facilitate the acquisition of conditional discriminations (e.g., Litt & Schreibman, 1981), but *reinforcer-probe trials* reveal that the class-specific consequences themselves become members of the equivalence classes, thereby increasing the number of class members that can be added by teaching a single conditional discrimination (e.g., Dube, McIlvane, Mackay, & Stoddard, 1987; Dube, McIlvane, Maguire, Mackay, & Stoddard, 1989). From our example above, when pictures of the marshmallow or juice are presented as sample or comparison stimuli, they are matched with the related A, B, C, or D stimuli (i.e., these are the reinforcer probes). Further, the A, B, C, and D stimuli prove to be interchangeable with each other, indicating equivalence-class formation (e.g., Dube et al., 1987, 1989). Thus, the class-specific reinforcer can also serve as a node for class formation; in this example, the D stimuli could have become class members only by virtue of their relation to the class-specific consequences held in common across the trained relations.

These sorts of findings also carry important implications for equivalence-based instruction. First, differential-outcomes procedures provide another route to producing more emergent relations with a given amount of training, because the reinforcers join the respective classes. Second, equivalence-class formation can result from identity match-to-sample training when class-specific reinforcers are utilized (e.g., Dube et al., 1987, 1989), and for certain target populations, identity training is more easily mastered than the arbitrary training that is more typical in equivalence research (e.g., Pilgrim, Jackson, & Galizio, 1990; Zygmont et al., 1992).

Studies are beginning to explore class-specific reinforcement procedures as a route to increasing the power of equivalence-based applications. To illustrate, preschool children who could count but otherwise scored poorly on math pretests were first taught to match

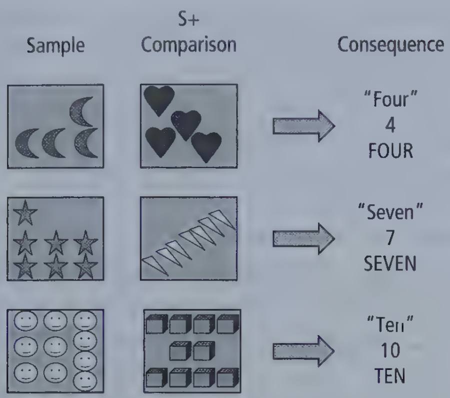

Figure 19.17 An illustration of the trained conditional discrimination. Each row represents a trained relation, with sample stimuli presented in the left column, the S+ comparison in the middle column, and the compound consequences that followed selection of the S+ in the right column. Note that the consequence for any given trial included the spoken word and either the numeral or the written word.

pictures with equal quantities of objects totaling 4, 7, or 10 (e.g., given 4 moons as sample, selecting 4 hearts rather than 7 lightning bolts or 10 squares; Luffman, 2012). Incorrect matches produced a brief buzzer, while correct matches produced a two-part class-specific consequence. Every correct match produced the corresponding spoken quantity value (e.g., "Four!") and one of two visual stimuli, the corresponding numeral (e.g., 4) or the written word (e.g., FOUR), each presented on half of the relevant trials. Figure 19.17 summarizes the training; each row of the figure presents an example of the matches that were taught, with the sample stimulus presented in the left column, the correct comparison in the middle column, and the possible consequences in the right column.

On the probe trials that followed this teaching, the children demonstrated class-consistent matching of each quantity, numeral, written word, and spoken word. Later teaching phases arranged the same compound consequences for accurately matching quantities of objects to a "+ 1" addition problem (e.g., given four objects, selecting "3 + 1," rather than "6 + 1" or "9 + 1"; AB training) and then for matching quantities of objects to a "+ 2" addition problem (e.g., given four objects, selecting "2 + 2," rather than "5 + 2" or "8 + 2"; AC training). Figure 19.18 shows all of the stimuli presented in AB and AC conditional discrimination training, including the class-specific consequences.

After completing the three teaching phases, probe performances documented the emergence of three equivalence classes with at least six members (i.e., a quantity of objects, the corresponding numeral, spoken and written words,

Stimulus Sets Used in Conditional Discrimination Training

A Quantities Trained	B + 1 Stimuli	C + 2 Stimuli	Consequences
4	3 + 1	2 + 2	"Four," 4, FOUR
7	6 + 1	5 + 2	"Seven," 7, SEVEN
10	9 + 1	8 + 2	"Ten," 10, TEN

Figure 19.18 Stimulus sets used in conditional discrimination training. Note that the consequence for any given trial included the spoken word and either the numeral or the written word.

"+ 1" and "+ 2" addition problems), any of which could be matched to any other interchangeably by children who had been unable to do so prior to training. (Probe batteries were presented just before and just after each training phase.) In this example, EBI resulted in the symbolic relations defining of a rudimentary but fundamental start to understanding mathematics.

Three-term Contingency Training

As noted previously, the acquisition of arbitrary conditional discriminations has sometimes proved challenging for young children and individuals with developmental delays. Thus, for both practical and theoretical reasons (Sidman, 1994, 2000), the possibility of generating equivalence classes based on **simple discrimination**, or three-term contingency, training has been explored, and with promising results (e.g., Debert, Matos, & McIlvane, 2007; Pilgrim, Boye, Hogan, & Groff, in press; Sidman, Wynne, Maquire, & Barnes, 1989). Indeed, the ease with which simple discriminations are typically acquired suggests considerable potential for this approach to applications of EBI.

To illustrate, consider a follow-up to the math teaching program described above. In this case, class-specific consequences were arranged again, but for simple discrimination training (Yonkers, 2012). Four young children with learning disabilities were identified by their teachers as needing extra help in basic math skills. The first training phase taught three simple discriminations with the correctly oriented numerals 4, 7, or 10 as the S+ stimuli. For each discrimination, the two S− stimuli presented the S+ numeral in either an upside-down or a 90° orientation. Figure 19.19 illustrates a trial presentation for each of the three discriminations, with the S+ and two S− stimuli appearing in three of the four corners of the computer screen.

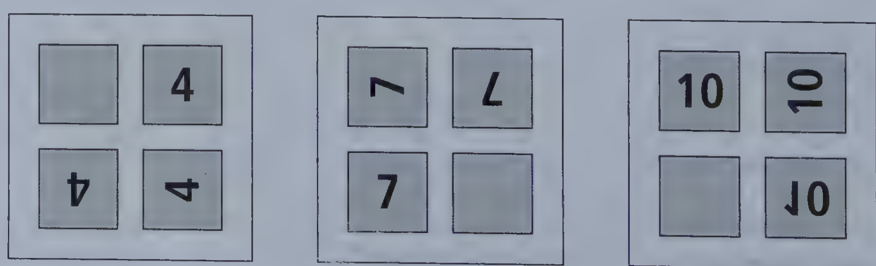

Figure 19.19 An illustration of example training-trial configurations, one with each of three trained simple discriminations.

Selecting either S− stimulus produced a buzzer, while selecting the S+ produced a compound class-specific consequence consisting of the spoken numeral name (e.g., "Four!") and the corresponding written word (e.g., FOUR), as illustrated in Figure 19.20.

Rapid acquisition of these simple discriminations was followed by conditional discrimination probe trials in which the spoken word, the written word, and the numerals were matched class-consistently, regardless of which served as sample and

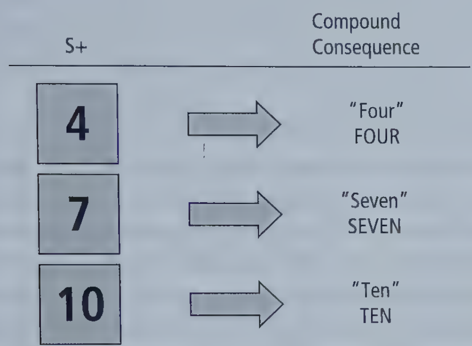

Figure 19.20 An illustration of the trained simple discriminations. Each row represents the S+ stimulus in the left column, and the compound consequences that followed selection of the S+ in the right column.

which as comparison. Additional simple discriminations were taught in subsequent training phases, in which the stimuli presented depended on each child's skill level, as measured by pretests. For the children with the lowest pretest scores, the B stimulus set consisted of correctly oriented "+ 1" addition problems (i.e., 3 + 1, 6 + 1, and 9 + 1), while the C stimulus set consisted of correctly oriented "+ 2" problems (i.e., 2 + 2, 5 + 2, and 7 + 2). One training trial of each type is illustrated in Figure 19.21; Figure 19.22 presents the S+ stimuli for each of the nine trained simple discriminations.

Again, selecting one of the correctly oriented S+ stimuli, rather than an upside-down or sideways presentation of the problem, resulted in the same class-specific consequences used for numeral training (i.e., the appropriate spoken and written number name, also illustrated in Figures 19.21 and 19.22). For children with more advanced skills, multiplication problems or Roman numerals were presented as stimulus sets, illustrating the flexibility of this approach to meet individual children's needs. Upon completion of the simple discrimination training with differential outcomes, match-to-sample probe tests documented the formation of equivalence classes (e.g., 4, "Four", FOUR, 3 + 1, and 2 + 2). Figure 19.23 illustrates just a few of the many probe arrangements made possible by the training program, with a sample stimulus presented in the center of the screen and comparison stimuli presented in three of the four corners of the screen. In this

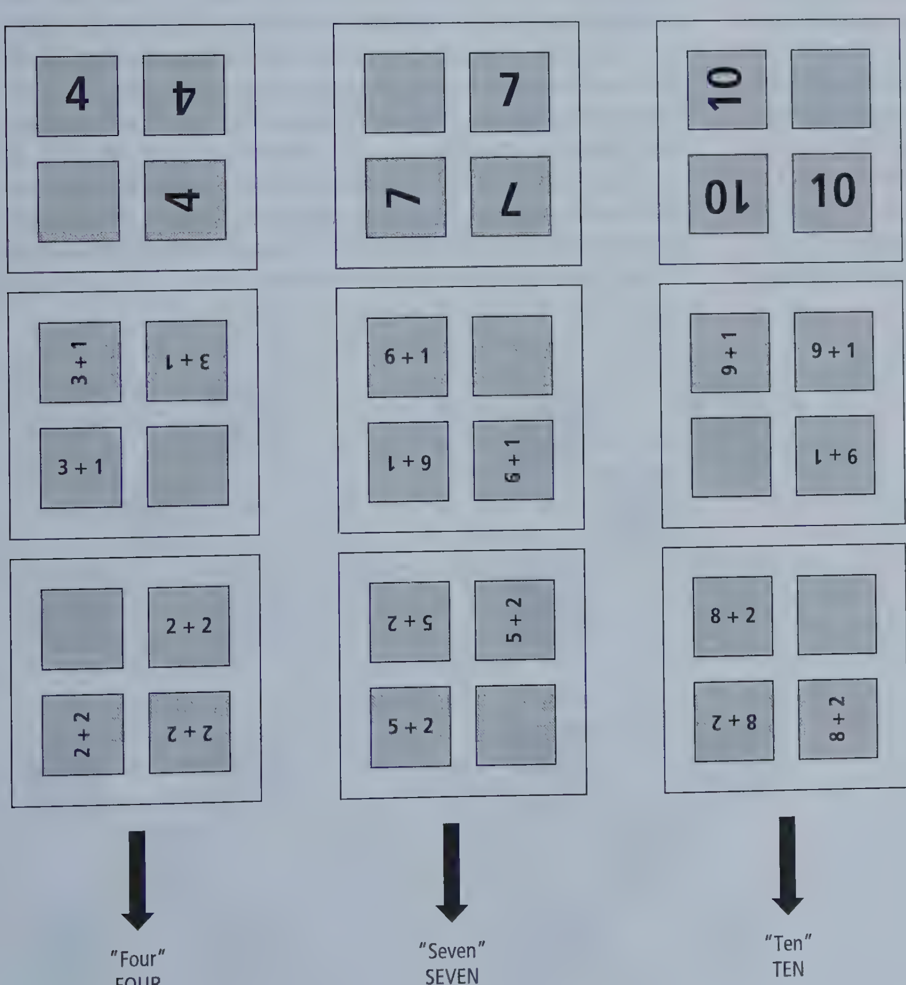

Figure 19.21 Illustration of a trial presentation with each of the nine trained simple discriminations. Each row represents trials with a particular stimulus set (A, B, or C), and each column represents trial types for which the same class-specific compound consequence was programmed, as indicated in the bottom rows.

Stimulus Sets Used in Simple Discrimination Training

A	B	C	Consequences
Numerals	+ 1 Stimuli	+ 2 Stimuli	
4	3 + 1	2 + 2	"Four," FOUR
7	6 + 1	5 + 2	"Seven," SEVEN
10	9 + 1	8 + 2	"Ten," TEN

Figure 19.22 A representation of all of the S+ and consequence stimuli presented during simple discrimination training.

EBI program, then, nine rapidly learned simple discriminations resulted in three five-member equivalence classes, as evidenced by more than 60 emergent conditional performances. These findings not only established the feasibility of such an approach to EBI but also provided a striking demonstration of the efficiency of EBI for producing generative and functional symbolic skills.

APPLICATIONS AND GENERALITY

The past years have witnessed enthusiastic attention to the possibility that equivalence-based instruction might be utilized creatively to establish or enhance performances across varied participant populations and across an increasingly broad range of target skills. The inherent flexibility of the equivalence paradigm, in which literally any stimulus combination can be employed, and the increasing variety of effective teaching and testing procedures that it has inspired, make the approach particularly attractive to applied behavior analysts. As each new application is documented, the generality of the equivalence outcome is further confirmed, a critical issue in the development of any scientific concept. In the sections that follow, some highlights from the accumulating application literature will be reviewed, to illustrate the scope and the promise of the equivalence approach to instruction with children and adults with intellectual disabilities, young typically developing children, adult clinical populations, and college students.

Children and Adults with Intellectual Disabilities and Young Typically Developing Children

To date, these populations stand as the major recipients of equivalence-based applications, because skill acquisition is a necessary and ongoing focus for such individuals. Important categories of EBI focus have included language- and number-skills training as well as other functional academic and life skills.

Language-Skills Training

Perhaps the greatest advances in programmatic EBI are found in the area of language-skills training. Building on Sidman's (1971; Sidman & Cresson, 1973) original findings, a number of studies have replicated the formation of equivalence classes as a basis for establishing rudimentary reading skills (e.g., Elias, Goyos, Saunders, & Saunders, 2008, with adults with intellectual disabilities; Osborne & Gatch, 1989, with hearing-impaired preschool children; Sidman, Cresson, & Willson-Morris, 1974, with two boys with Down syndrome), where each class included a spoken word or sign (demonstrated in American Sign Language), a written word, and a picture or object. Participants, all of whom were nonreaders at the start, went on to sign or orally name both the pictures/objects and the written words following class formation.

As illustrated earlier in this chapter, another group of studies has demonstrated that spelling performances can be effectively incorporated into an equivalence approach (e.g., de Souza et al., 2009; Goyos, Souza, Silvares, & Saunders, 2007; Melchiori, de Souza, & de Rose, 2000). The constructed-response procedure has often been used for this purpose whereby, in the presence of a spoken or written word, the participant's task is to produce that word by selecting a series of letters or syllables from a choice pool, in

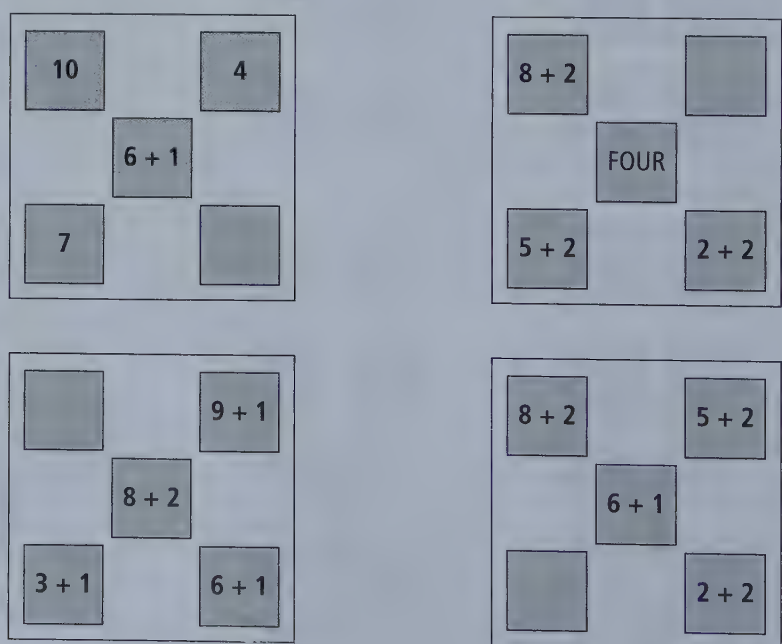

Figure 19.23 Examples of conditional discrimination test-trial arrangements.

order, either by touching each choice sequentially on a computer presentation or by moving letter tiles in a table-top task. This teaching approach has proven effective with a range of participant groups including preschoolers, young students from regular and from special education classes, and adult nonreaders.

One particularly exciting outcome of the studies just cited has been that spelling improvements successfully generalized to words that were not directly targeted in the teaching steps. As was the case in the work described above with compound sample stimuli, it seems that the individual components, or units, of the trained compounds came to exert stimulus control on their own (e.g., the individual letters, in the case of spelling). Thus, when these smaller units appeared in novel arrangements (e.g., when new words were presented), appropriate responses (e.g., accurate spelling sequences) were possible. The ability to produce and recombine minimal units (e.g., words, syllables, phonemes, letters) in the presence of novel stimulus compounds is clearly essential to many functional language skills, such as reading and spelling. Not surprisingly, then, another important development in equivalence-based language-instruction programs has involved incorporating steps to deliberately facilitate such recombinations, also known as *recombinative generalization*. The general strategy involves teaching with compounds that have been specifically chosen to include overlap in the individual units that will be necessary for correct responding to novel compounds. For example, a child might be taught to select the written words MAP, SAP, MUM, or SET correctly upon hearing the corresponding spoken word, and then prove able to select the novel words MET or SUM on test trials. This teaching arrangement is sometimes described as *matrix training*, to emphasize the designed overlap in units across training and testing compounds. The key is to establish all of the prerequisite units for successful performance prior to test trials with the new combinations. (For further elaboration and examples, the interested reader should consult, as representative sources, de Souza et al., 2009; Hanna et al., 2011; Mueller, Olmi, & Saunders, 2000).

One group of behavior analysts has extended the generality of this training strategy considerably with a sophisticated, comprehensive, and ongoing reading-instruction program for children in Brazil who have experienced repeated failure in the public school system (de Souza et al., 2009). Many of the children are from families with low socioeconomic status and they carry significant risk for school drop-out. The reading curriculum as a whole incorporates many of the findings described in this chapter as contributing to maximal effectiveness, and it has produced many first-time readers as a result (e.g., de Rose, de Souza, Rossito, & de Rose, 1992; Matos & Hubner-D'Oliveira, 1992). By way of overview, some key characteristics of the early instructional phases include a matching-to-sample procedure with constructed responses and a matrix training approach that builds on an interesting feature of the Portuguese language. Many Portuguese words are formed by consonant-vowel syllables (e.g., BOLA, which means "ball" in English, and LATA, which means "can"). Recombinations of these syllables form new words (e.g., BOTA, which means "boot" in English), thus setting the stage nicely for training designed to produce generative reading repertoires, with syllables as the minimal units. For the constructed responses, students learn to select the appropriate sequence of syllables (rather than individual letters, as in the spelling studies above) given a printed word, dictated word, and picture. AB (spoken word to picture matching) and AC (spoken word to written word matching) conditional discriminations are also taught, as in several of our earlier examples (e.g., Sidman, 1971).

Tests at this point reveal the formation of equivalence classes (i.e., spoken word, picture, and written word) both for trained words and for recombinative generalization words. Significant improvements have also been obtained in reading and in spelling, both in the syllable-constructed response format and in cursive writing, again with training and generalization words alike. Subsequent teaching phases of this integrated instructional program move from acquisition of reading and writing syllables to whole words to sentences and short stories, and refinements continue. This increasingly complete reading curriculum has now benefited more than 3000 students at reading centers in multiple schools throughout Brazil, and may well stand as the single most comprehensive application of equivalence-based instruction in existence to date.

Number-Skills Instruction

Just as basic reading comprehension has been approached through EBI, so has basic numeric comprehension, with targets ranging from simple number classes to more complex mathematical concepts. Examples of the former have involved match-to-sample training in which participants learn to select the appropriate quantity of objects or pictures (e.g., *, **, or ***) in the presence of dictated number names (e.g., "one," "two," and "three"), and the appropriate numeral (e.g., 1, 2, or 3) in the presence of the same number names (i.e., AB and AC conditional discriminations). Probe tests following such training have reliably resulted in evidence of equivalence-class formation, with each class including a dictated name, a quantity, and a numeral (e.g., Gast, VanBiervliet, & Spradlin, 1979; Maydak, Stromer, Mackay, & Stoddard, 1995; both with individuals with intellectual disabilities). Emergent matching of quantities and numerals supports an interpretation of number comprehension, and participants come to name the quantities and the numerals correctly as well. Variations on this training have also established number names from two unfamiliar languages (i.e., Native American Ojibwe and Dakota words) as equivalence-class members (Haegele, McComas, Dixon, & Burns, 2011) with typically developing preschoolers.

These simple number classes have been elaborated in several ways in subsequent studies. One example was described previously (Luffman, 2012) in which match-to-sample training using compound class-specific reinforcers was conducted with young typically developing children, and probe performances documented the formation of six-member equivalence classes that included quantities, numerals, spoken number names, written number names, and $X + 1$ and $X + 2$ arithmetic problems for each of three values (i.e., 4, 7, and 10; see Figure 19.18 for all stimulus sets). Each class member was matched accurately to every other class member, yielding hundreds of emergent numeric relations, after teaching only AA, AB, and AC conditional discriminations. The children in this study also learned to perform a constructed response. For each quantity sample presented during training, they were required to slide the

appropriate number of beads on an abacus, prior to the presentation of comparison stimuli; that is, a class-specific constructed-observing response was required. At the study's conclusion, generalization trials were presented in which the three numerals served as either samples or comparisons, and novel addition problems equaling 4, 7, or 10 (e.g., 2 + 2, 4 + 3, 5 + 5) served as comparisons or samples, respectively. (Note that, as illustrated in Figure 19.18, all values from 1 through 10 had been presented during training). The children made accurate matches on these novel trial types, and they performed the appropriate constructed response to the novel sample combinations, thus demonstrating recombinative generalization of the values.

Many beginning math learners struggle to understand and respond accurately with respect to fractions and decimals, and EBI has been designed to facilitate these more complex mathematical concepts as well (e.g., Hall, DeBernardis, & Reiss, 2006; Lynch & Cuvo, 1995). To illustrate, match-to-sample training was conducted with seven 11- to 13-year-old students identified as having math difficulties; grade-equivalent math scores for these fifth- and sixth-graders ranged from 3.0 to 3.7 (Lynch & Cuvo, 1995). AB and then BC conditional discriminations were taught in which the A stimuli included 12 fractions expressed as ratios (e.g., 3/5), the B stimuli included 12 fractions represented pictorially (i.e., as a grid of 100 squares with the appropriate number of squares shaded), and the C stimuli included 12 values presented as decimals (e.g., 0.60). The top portion of Figure 19.24 illustrates the trained and tested relations. In contrast to generally poor pretest scores, all seven students improved dramatically, often to near-perfect levels, on the fraction-to-decimal probe tests (i.e., AC and CA) indicative of equivalence-class formation. Thus, 12 equivalence classes consisting of a fraction, a shaded grid, and a decimal value emerged, and a subsequent AD training step with 12 new fractions (D stimuli) expanded the classes to include a fourth interchangeable member. Results were mixed on paper-and-pencil tests for solving fractions with no choices provided, and on match-to-sample generalization tests involving novel fractions, with some of the students showing large improvements from pretests and others none at all. It might be noted that the teaching procedures in this early study did not utilize a matrix-training approach.

Another obviously important functional-skill category for young children and individuals with disabilities involves money equivalencies, in which dictated or printed prices and various coin or dollar combinations must become interchangeable (see our example from Figure 19.7). This target has also been the subject of a number of EBI studies (e.g., Keintz et al., 2011; Stoddard, Brown, Hurlbert, Manoli, & McIlvane, 1989) using the match-to-sample procedure. In an early classic report (McDonagh, McIlvane, & Stoddard, 1984), a woman with moderate intellectual disability was taught to match two different coin combinations to a printed price for each of three values (5, 10, and 15 cents). With no further training, she could then match the coin combinations to each other and give the values of each, demonstrating equivalence-class formation. The three-member classes were expanded successfully by teaching additional coin combinations for some of the values, and these results were replicated systematically across multiple individuals with intellectual disabilities (e.g., Stoddard et al., 1989). In a more recent illustration (Keintz et al., 2011), two preschoolers with autism received training with three dictated coin names (the A stimuli; "penny," "nickel," and "dime"), three actual coins (the B stimuli; a penny, a nickel, and a dime), three printed prices (the C stimuli; \$0.01, \$0.05, and \$0.10), and three dictated prices (the D stimuli; "1 cent," "5 cents," and "10 cents"). After learning AB, BC, and DC conditional discriminations (see the bottom half of Figure 19.24), both children demonstrated four-member equivalence classes including the dictated coin and price names, the actual coins, and the written prices, and both named each of the coins. Collectively, the results from these studies demonstrate the great potential of EBI for establishing symbolic equivalencies involving large numbers of individual coin relations.

Other Functional Skills

A range of skills in addition to those involving basic language and number classes have been established through EBI, providing further testament to the considerable flexibility of this teaching approach. For children and adults with cognitive disabilities and typically developing children, several examples will serve to reflect the variety of performances that have been targeted to meet specific needs of the individual participants.

One interesting study (Arntzen, Halstadtrø, Bjerke, & Halstadtrø, 2010) focused on facilitating music skills for a 16-year-old with autism and intellectual disability; the boy was interested in music and could play a few simple songs on a keyboard when guided by a color-code that showed which note to play. The equivalence-based training was designed to teach him to read and play musical chords. For each potential class, the stimulus sets in this study included (a) the name of a chord in Norwegian (the boy's second language); (b) a keyboard diagram with dots indicating finger placement; (c) a musical staff with the chord represented as notes; and (d) the name of the chord in Vietnamese (the boy's first language). Across the phases of the study, eight different major chords and an equal number of minor chords were targeted; none of these chords were played or named correctly on a pretest. Posttest results verified the emergence of a large number of four-member equivalence classes. The authors also reported that the boy continued to use the chords after the study concluded, and they recommended EBI approaches for establishing other hobby skills, to possibly enhance the lives of individuals with intellectual disabilities. A similar study with typically developing preschoolers was also effective in establishing simple music skills with an equivalence-based approach (Tommis & Fazey, 1999). Again, improvements in playing simple melodies were maintained, at a 7-week follow-up test in this case.

Several studies have focused on expanding sources of stimulus control for key functional skills in young children and adults with disabilities. For example, activity schedules are an important aid to helping children work independently in many special education classrooms (e.g., MacDuff, Krantz, & McClannahan, 1993; McClannahan, MacDuff, & Krantz, 2002). Typically, activity schedules present a sequence of pictures, one at a time, each of which indicates a particular task to be completed. To make the developmentally appropriate shift from control by pictures to control by written words, an equivalence-teaching approach was arranged for two 6-year-old children with autism who responded accurately to picture schedules (Miguel, Yang, Finn, & Ahern,

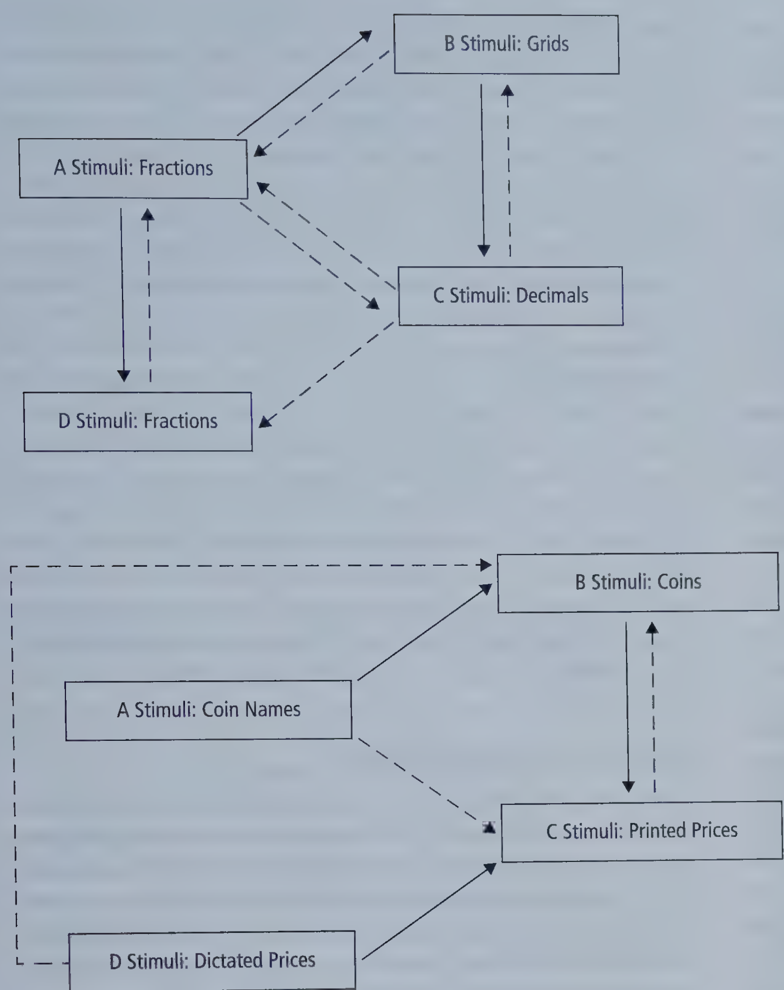

Figure 19.24 The top half of the figure presents a schematic representation of trained (solid arrows) and tested (dashed arrows) conditional discriminations from Lynch and Cuvo (1995). The bottom half of the figure presents the same information from Keintz, Miguel, Kao, and Finn (2011).

2009). After being taught to match six activity-schedule pictures to their dictated names (AB training) and six corresponding written words to the same dictated names (AC training), both children demonstrated accurate responding to activity schedules with written words, as well as accurate matching of words and pictures, indicating comprehension of the words, and oral reading. A similar strategy was used (Rehfeldt & Root, 2005; Rosales & Rehfeldt, 2007) to augment the manding skills of male adults with severe intellectual disabilities who had learned to request items with pictures via the Picture Exchange Communication System (PECS) (Frost & Bondy, 1994). After successful picture-exchange requests had been established, participants were taught to choose the correct picture given its dictated name and to choose the corresponding written word given the same dictated names (AB and AC conditional discriminations). Although unable to do so on pretests, all participants demonstrated equivalence-class formation, matching pictures to their written words and vice versa, and they successfully requested items with the appropriate written word. Some of the men also named the written words and requested items by name as well as by written-word exchanges. For the participants who received maintenance tests 1 month after training (Rosales & Rehfeldt, 2007), lasting improvements to functional communication were demonstrated.

Equivalence-based instruction has also been used to teach academic content such as geography to children with disabilities, as well as to typically developing children. For example, basic geography lessons were presented to two boys with autism by teaching them to match a drawing of each of nine states to the dictated state name (AB training) and then to match the name of the state's capital city to the state drawing (BC training; LeBlanc, Miguel, Cummings, Goldsmith, & Carr, 2003). Where all pretest scores were at approximately chance levels of accuracy for both boys, posttests revealed strong emergent performances indicative of equivalence-class formation; state names were matched to their capitals and vice versa, and each trained relation was reversible. One of the boys also demonstrated perfect accuracy on vocal posttests in which correct responses had to be produced orally (rather than selected) in response to relevant geography questions about the states involved in training (e.g., "What is the capital of Florida?"). This teaching approach was replicated systematically in a study with five adolescents with fragile X syndrome where three state names, drawings, and capitals were taught (Hall et al., 2006). In another variation, also involving geography content, five typically developing 6-year-olds were taught AB and BC intraverbal sequences rather than match-to-sample performances (Perez-Gonzalez, Herszlikowicz, & Williams, 2008). In this procedure, a geography question was presented orally (e.g., "What is the capital of Argentina?"), and the child was taught to give the correct answer orally. Thus, the procedure involved production of an oral response rather than the

more typical selection of a stimulus in a match-to-sample task (i.e., topography-based rather than selection-based responding). The stimulus sets included (a) two countries; (b) two capital cities; and (c) two city parks. After mastering the trained intraverbal sequences (i.e., country-capital and capital-park), probe trials presented novel questions with each possible combination of elements (i.e., capital-country, park-capital, country-park, and park-country). Results showed accurate emergent responding on at least some probe types for most participants.

Another important research direction for EBI in applied behavior analysis involves utilizing equivalence classes as an explicit means to promote generalization after teaching other functional skills. That is, if a new performance is taught in the presence of one stimulus setting, and that stimulus is a member of an equivalence class, we might expect the performance to be controlled by other members of the class as well (i.e., the transfer-of-function effect). Although this possibility has received relatively little attention in applied work, some initial exploration has been promising. Taylor and O'Reilly (2000) worked with six participants with mild intellectual disabilities to establish a response chain of grocery-store shopping skills. A task sequence (e.g., enter the store, consult a two-item shopping list, find the first item, place it in the cart, etc.) was trained first in a classroom, and then in a particular grocery store for all six. For two participants, this constituted the complete training (i.e., single-instance training). For another two participants, the same task-sequence training was conducted in two additional grocery stores (i.e., multiple-exemplar training). For the remaining two participants, single-instance training was followed by EBI. AB and BC conditional discriminations were taught with spoken words ("Supermarket," "Shop," and "Restaurant"), the corresponding written words, and photographs taken from inside each setting. An interesting feature of the training was that three different photographs of supermarket settings were presented across training trials. Probe trials for these participants documented the formation of three equivalence classes, each including a spoken word, a written word, and the relevant photographs. After training, shopping skills were evaluated for all participants in a generalization grocery setting. The task sequence was followed accurately and equally well for the participants who received EBI and multiple-exemplar training, while those who received only single-instance training performed more poorly. Although this study is limited by the small number of participants in each teaching condition, the results suggest that EBI can provide the same positive impact on generalization as more costly and labor-intensive training in multiple sites. Certainly, these are findings worthy of further exploration.

A final and significant category of equivalence-based instruction with children involves programs designed to facilitate skills related to sensory deficits, such as vision or hearing. One illustrative study used an equivalence approach to teach Braille letter naming to four children (ages 7 to 12 years) with degenerative visual impairments (Toussaint & Tiger, 2010). All four students could name printed letters, but despite having a year or more of classroom Braille instruction, none demonstrated proficiency in reading Braille words. The stimulus sets used for teaching and testing included (a) Braille letters; (b) printed letters; and (c) spoken letter names, for 5 to 26 letters, depending on the participant. With printed letter-name relations (BC relations) already intact, teaching focused on having the children match Braille letters to printed ones (AB relations). On subsequent posttests, all four children demonstrated strong emergent matching between printed-letter samples and Braille comparisons, and between spoken name and Braille comparisons. They also named the Braille letters, verifying the formation of equivalence classes that provided a basis for further Braille reading instruction. With respect to hearing deficits, another program of study has undertaken the goal of establishing symbolic function for auditory stimulation provided by a cochlear implant in children with deafness (Almeida-Verbu et al., 2008; da Silva, de Souza, & de Rose, 2006). To illustrate, 6- to 9-year-old children with early-onset deafness first received AB and AC conditional discrimination training with all visual stimuli (Almeida-Verbu, et al., 2008). After three-member equivalence classes were demonstrated, a new conditional discrimination was taught with auditory stimuli as samples (DC training). All participants then demonstrated class expansion, indicating that the sounds had become the symbolic equivalent of the existing class members (e.g., D1 was interchangeable with A1, B1, and C1, and so on). These preliminary results suggest great promise for helping young children learn the meaning of sounds once cochlear implants make auditory stimulation available to them, perhaps for the first time in their lives.

Adult Clinical Populations

Although a relatively small category compared to many we have reviewed, applications of EBI to adult clinical issues have been explored in several studies, noteworthy because of the potential that is exemplified for these populations. As a case in point, individuals with acquired brain injury or illness often display deficits for which equivalence approaches seem well suited, such as the inability to provide or respond to words for everyday objects, events, or people. One study (Cowley et al., 1992) focused on three adult men with brain injury who were unable to relate their therapist's name to his or her face, even after many months of working together—a problem for independent functioning within the rehabilitation facility. The solid arrows in Figure 19.25 depict the stimulus relations that were demonstrated by each of the men at pretest for each of three different therapists. The relations targeted in training are depicted by the bold arrow, and the potentially emergent relations are indicated by the broken arrows. Posttest results revealed equivalence-class formation for all three men; that is, spoken names, written names, and faces were matched together in any combination. The two men who received the test were also successful at providing oral names for their therapists' faces. Facial-emotion recognition was targeted in another study with three adults with brain injury (Guercio, Podolska-Schroeder, & Rehfeldt, 2003). Although these participants were unable to do so on pretests, learning to match two sets of facial expressions to their appropriate written labels (i.e., happiness, sadness, and anger; AB and CB training) produced significant improvements in matching different representations of the same emotion to each other, and in providing correct oral labels for those emotions.

The field of gerontology represents another obvious target for equivalence approaches, although work in this area is in its infancy. Although it is clear that some elderly individuals demonstrate equivalence-class formation readily (e.g., Perez-Gonzalez & Moreno-Sierra, 1999; Saunders, Chaney, & Marquis, 2005), it is also apparent that age matters (Wilson & Milan, 1995), with

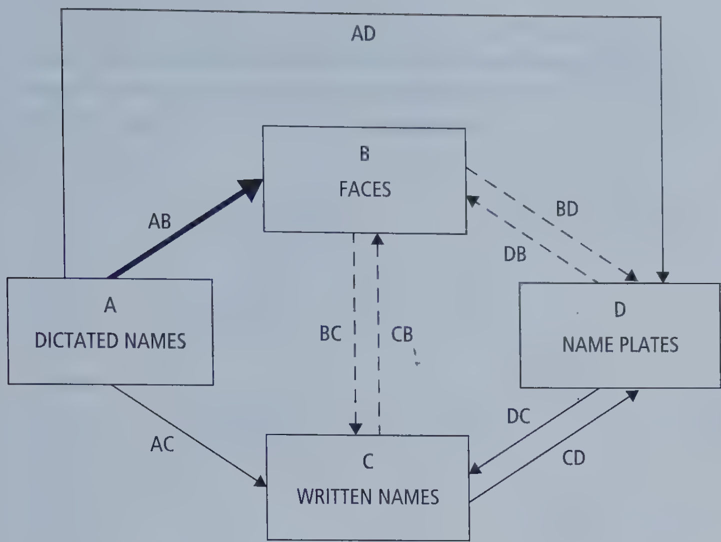

Figure 19.25 A schematic representation of the existing (thin solid arrows), trained (bold solid arrow), and tested (dashed arrows) conditional discriminations.

Using Stimulus Equivalence Procedures to Teach Name-face Matching to Adults with Brain Injuries" by B.J. Cowley, G. Green, and B. Brounling-McMorrow, 1992, Reproduced with permission of John Wiley & Sons Inc.

older participants (62 to 81 years old) less likely to demonstrate class formation than young adults (19 to 22 years old). Further, a correlation has been noted (Gallagher & Keenan, 2015) between demonstrations of equivalence-class formation and scores on the Mini Mental Status Examination (MMSE), a widely used assessment of cognitive impairment in the elderly. Indeed, the ability to demonstrate equivalence-class formation may prove to be a more sensitive measure of impairment, in that deficits in class formation were present for individuals with MMSE scores above those indicative of cognitive difficulties. One investigation of a participant diagnosed with Alzheimer's disease (an 84-year-old woman with an MMSE score of 20, or mild cognitive impairment) found evidence of delay-identity matching but not equivalence-class formation (e.g., Steingrimsdottir & Arntzen, 2011; see also Steingrimsdottir & Arntzen, 2014). Equivalence approaches may thus have much to offer in the way of assessing cognitive declines. Whether EBI can be used effectively to target lost skills, or to facilitate maintenance of remaining skills at least in individuals with mild impairment, remains to be explored.

The broad domain of health care would seem to hold many possibilities for skill improvement based on EBI. In one innovative study relevant to the critical issue of obesity (Hausman, Borrero, Fisher, & Kahng, 2014), researchers sought to teach college students to make accurate estimations of portion size because portion size can be directly related to caloric intake, especially for overweight individuals (e.g., Burger, Fisher, & Johnson, 2011). Nine students, five of whom were overweight or obese, were taught to match measuring cups filled at a given level (i.e., one-quarter cup, one-half cup, and one or two cups of a dry food) to a quantity of the same food piled on a plate, and vice versa (i.e., AB and BA training). They were also taught to match one of four measuring aids (i.e., a golf ball, tennis ball, baseball, and softball) to each measuring cup amount, and vice versa (i.e., BC and CB training). Figure 19.26 illustrates these training procedures. At pretest, posttest, and 1-week maintenance and generalization tests, a large plastic container filled with a food was presented, and each participant was asked to move one-half cup of the food to a plate. No cues, aids, or measuring cups were provided. The generalization tests involved novel foods that had not been presented during training sessions.

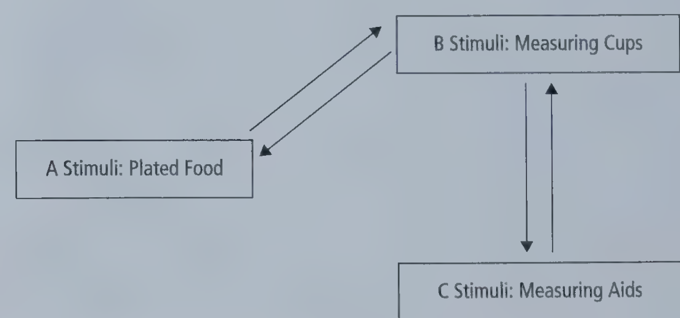

Figure 19.26 A schematic representation of the trained conditional discriminations.

All nine participants demonstrated improvements in the accuracy of their portion estimates from pretraining to posttraining and for seven, those improvements were maintained 1 week later. Five participants demonstrated similar accuracy with at least one novel food in the generalization tests. Thus, a brief teaching intervention (50 to 90 trials) was sufficient to impact a potentially influential skill relevant to healthful eating practices. Further investigation of EBI for health-related skills is called for.

In the College Classroom

The benefits to be gained from programmed instructional techniques based on behavioral principles have long been noted for university-level instruction (e.g., Keller, 1968, 1982; Skinner, 1968), and modern technology has only increased the feasibility of providing course content in a more effective manner. Of course, many college classes or course sequences require facility with large sets of basic facts and relations before advanced study is possible. Unfortunately, the rote memorization of facts that characterizes some common study techniques (e.g., flash cards) often fails to suffice for true understanding of the subject. Instead, comprehension of the sort at issue throughout this chapter is necessary for progress. It only stands to reason, then, that behavior analysts would apply equivalence-based instruction to teaching university-course content, extending the generality of the instructional approach to much more complex stimulus sets, a sophisticated group of learners, and new settings.

One early study of this type (Fields et al., 2009) sought to teach introductory psychology students concepts of statistical interaction in a two-way analysis of variance, a subject matter that has presented challenges for many learners at this level. Match-to-sample training established AB, BC, and CD conditional discriminations with the four sets of stimuli depicted in Figure 19.27, and probe performances documented the emergence of four classes, each with four

A1	B1	C1	D1
	Aggression was directly related to sleep deprivation for both kids and adults. For each level of sleep deprivation, a decrease in age produced a constant increase in aggression. Degree of aggression in kids and adults did not intersect at any level of sleep deprivation.	No Interaction	Independent variable A produces the same directional change in responding for all values of independent variable B. Changing the value of independent variable B produces a constant change in the effect of each level of independent variable A. The effects do not intersect.
A2	B2	C2	D2
	In kids, aggression was inversely related to sleep deprivation. In adults, aggression was directly related to sleep deprivation. Age reversed the effect of sleep deprivation on aggression. Levels of aggression seen with kids and adults intersected at an intermediate level of sleep deprivation.	Crossover Interaction	Changing the value of independent variable B reverses the effects of independent variable A, and these effects intersect.
A3	B3	C3	D3
	In kids, aggression was directly related to sleep deprivation. In adults, aggression was inversely related to sleep deprivation. Age reversed the effect of sleep deprivation on aggression. Levels of aggression in kids and adults did not intersect at any level of sleep deprivation.	Divergent Interaction	Changing the value of independent variable B reverses the effects of independent variable A, and these effects do not intersect.
A4	B4	C4	D4
	Aggression was directly related to sleep deprivation for both kids and adults. Increased sleep deprivation produced a larger increase in aggression in kids than in adults. Levels of aggression in kids and adults did not intersect at any level of sleep deprivation.	Synergistic Interaction	Independent variable A produces the same directional change in responding for all values of independent variable B. Changing the value of independent variable B enhances the effect of independent variable A. The effects do not intersect.

From "Equivalence Class Formation: A Method for Teaching Statistical Interactions" by L. Fields, R. Travis, D. Roy, E. Yadlovker, L. de Agular-Rocha, and P. Sturmey, 2009, Reproduced with permission of John Wiley & Sons Inc.

members. Each class included a line graph illustrating a particular statistical interaction, text describing the interaction shown in the graph, the label for the type of interaction, and text defining the interaction type. Interchangeability between the members of each of the four classes (i.e., no interaction, crossover interaction, divergent interaction, and synergistic interaction) indicated comprehension of the statistical concepts, based solely on the EBI. As further evidence, the students completed a paper-and-pencil multiple-choice test of the same interaction types but with novel graphs and graph descriptions, both before and after the match-to-sample training. After completing the 90-minute training, students showed significant improvement in test scores, from an average of approximately 50% on the pretest to an average greater than 90% on the posttest; all students earned scores corresponding to a grade of "A" or "B." Thus, the comprehension that emerged from training generalized to new exemplars. In contrast, a matched group of control students took the test twice with 90 minutes in between, but did not receive training. For these students, there was no change in test scores as a result of repetition, and 73% of them earned scores corresponding to a grade of "D" or "F."

Fienup, Covey, and Critchfield (2010) arranged an EBI program designed to take advantage of the generative power of class expansion or merger. The lesson content in this study was brain structures and functions, another complex subject matter consisting of a great number of interrelated facts. Volunteer undergraduate students received match-to-sample training with the stimuli illustrated in the top half of Figure 19.28. All possible transitive/equivalence relations were pretested and posttested following each phase of training. The diagram at the bottom of Figure 19.28 represents all tested relations with dashed lines and all trained relations with solid lines. The first phase of training established AB and AC conditional discriminations, and probe tests documented the formation of four three-member classes (i.e., ABC classes, each including the name of a lobe of the brain and two different functions corresponding to that lobe). The second training phase taught AD and AE conditional discriminations; again, four three-member classes resulted (i.e., ADF classes, each including the name of a lobe of the brain, a brain schematic depicting the location of the lobe, and a deficit caused by damage to that lobe). Probes for class merger/expansion tested for the emergence of all possible relations between the B, C, D, and E stimuli in each class. To sum, the five-member classes documented by 80 different stimulus relations in this study were generated by teaching a subset of only 16, in lessons that required only about 15 minutes—a tremendous efficiency in teaching.

The applications of EBI to college coursework would seem to be limited only by the teacher's creativity. Indeed, a number of different subject matters have been targeted with this teaching approach. Statistical concepts have been a frequent choice for instructional programs (e.g., in addition to those above, Albright, Reeve, Reeve, & Kisamore, 2015; Fienup, Hamelin, Reyes-Giordano, & Falcomata, 2011). Other targeted content has included concepts from research design (e.g., Lovett, Rehfeldt, Garcia, & Dunning, 2011; Sella, Ribeiro, & White, 2014; Walker & Rehfeldt, 2012), from diagnostic categories of disabilities (Walker, Rehfeldt, & Ninness, 2010); and from classes of drug names in psychopharmacology (Zinn, Newland, & Ritchie, 2015). Although all of these studies have demonstrated tremendous teaching efficiency in the number of emergent match-to-sample relations generated, compared to the number trained, some have extended that efficiency significantly by including generalization tests of various kinds. Generalization testing strategies have included probes for topography-based responding that was not targeted in training (e.g., orally naming stimuli or writing answers; Albright et al., 2015; Sella et al., 2014); probes presented in a different format (e.g., on multiple-choice paper-and-pencil tests akin to those used in traditional classroom settings; Albright et al., 2015; Critchfield & Fienup, 2010); novel stimulus presentations (e.g., Albright et al., 2015; Walker & Rehfeldt, 2012); and follow-up maintenance tests (e.g., Albright et al., 2015; Walker & Rehfeldt, 2012).

Finally, in addition to evaluating the success of EBI with improvements at the level of the individual participant (e.g., from pretest to posttest), some studies have also compared performances across groups. As noted above, Fields et al. (2009) compared students who received training to those who did not, and found significantly stronger performances after training. Fienup and Critchfield (2011) compared the outcomes of EBI instruction to those from two different groups—one that received no training and one that received training for all possible relations (i.e., all of the relations that were trained as well as those that were probed for the EBI group). The students with no training performed poorly on the comparison tests; the EBI and full-training groups did equally well, but the EBI group had received significantly less training. Zinn et al. (2015) compared a group of students receiving EBI to each of two control groups trained on a randomly selected (rather than interrelated) subset of the EBI training and probe trials. One control group was matched to the EBI condition with respect to the accuracy criterion required for training; the other was matched with respect to the total number of training trials presented. Probe performances following equivalence training were significantly superior to those of the unstructured-instruction groups. Lovett et al. (2011) compared a group of students trained with EBI to a group that received a standard lecture on the same subject matter, presented as a video. The two groups performed equally well in this comparison. If EBI is to have widespread impact on university teaching practices, further comparisons across teaching formats will continue to be an important direction for future research.

	Set 1	Set 2	Set 3	Set 4
A	Frontal Lobe	Occipital Lobe	Parietal Lobe	Temporal Lobe
B	Function 1: Involved in movement	Function 1: Involved in perceiving visual information	Function 1: Involved in perceiving touch	Function 1: Involved in auditory processing
C	Function 2: Involved in higher cognitive functions	Function 2: Involved in integrating color and shape	Function 2: Involved in integrating sensations	Function 2: Involved in memory formation
D				E	Damage causes impulsiveness	Damage causes problems with sight	Damage causes inability to perceive objects in space	Damage causes memory and hearing impairment

The bottom half of the figure presents a schematic representation of all trained (solid arrows) and tested (dashed arrows) conditional discriminations.

From "Teaching Brain-behavior Relations Economically with Stimulus Equivalence Technology" by D. Fienup, D. Covey, and T. Critchfield, 2010, Reproduced with permission of John Wiley & Sons Inc.

APPLICATIONS STEMMING FROM ALTERNATIVE THEORETICAL APPROACHES TO RELATIONAL RESPONDING

Sidman's (1994, 2000) theoretical account of equivalence-class formation holds equivalence to be a basic behavioral process, akin to reinforcement or discrimination in that individuals do not have to learn how to behave in accordance with these processes. Just as no one had to teach you to respond more frequently when your behavior produces a reinforcer, in Sidman's view, no one had to teach you to produce the patterns of responding defined as equivalence. Rather, basic behavioral processes, like equivalence by this view, are a direct outcome of the reinforcement contingencies in place. In other words, arranging a three- or four-term reinforcement contingency will automatically result in equivalence performances as long as no methodological features constrain or interfere (e.g., by creating competing sources of

stimulus control), at least for most human participants. Further, Sidman's view is that all elements of the reinforcement contingency (e.g., for a four-term contingency, that would include the sample stimulus, the comparison stimulus, the response, and the consequence) can function as equivalence-class members in a given context (again, as long as no methodological issues interfere). In keeping with this emphasis on the reinforcement contingency as the basis for equivalence, the EBI literature reviewed thus far has highlighted many creative arrangements of three-, four-, and even five-term training contingencies, with focus on the make-up of the classes made possible by those contingencies.

Alternative theoretical accounts of equivalence performances have also been developed since Sidman's seminal work on the topic (e.g., Sidman, 1971; Sidman & Cresson, 1973; Sidman & Tailby, 1982), as the phenomenon has been explored and extended, both experimentally and conceptually. The two most prominent of these alternatives are naming theory, developed by Horne and Lowe (1996) and colleagues, and relational frame theory (RFT), developed by Hayes, Barnes, and colleagues (e.g., Hayes, Barnes-Holmes, & Roche, 2001). A complete review of the literature related to these accounts is well beyond the scope of this chapter; Chapter 20 provides a careful examination of work based on RFT, and the interested reader can consult the references on naming theory provided in this chapter. Some discussion of the two positions is warranted here, however, particularly because of the practical strategies for producing emergent (or derived) behavior that follow from each theory. Thus, the necessarily brief overviews that follow are intended to introduce a few representative illustrations of application work based on the naming and relational frame theories, to provide the reader with a basis for further study of these productive directions in applied behavior analysis.

One key theoretical feature shared by the naming theory and RFT distinguishes these accounts from Sidman's (e.g., (2000). In both cases, emergent or derived responding is seen as learned behavior, rather than as a direct outcome of a reinforcement contingency. In other words, a specific learning history is viewed as necessary before a given contingency could give rise to emergent performances. The nature of the training history held to be necessary differs across the two accounts, providing the basis for differences in the application approaches to be described. For both accounts, however, emphasis is placed on training that produces a generalized or **higher-order operant class**. Higher-order operants are defined in terms of general relations between antecedents and responses, rather than in terms of specific stimuli and responses, and any given instance of antecedent control is seen as just one example of a more general relation (e.g., Catania, 1998). Generalized imitation is considered a classic example of a higher-order operant (e.g., Catania, 1998; Dinsmoor, 1995). Imitation is typically viewed as a correspondence between the actions of a model and those of an observer, rather than in terms of any specific modeled action or response, and imitative repertoires are generalized when they include novel correspondences that have not been directly taught. To give a further feel for the central role played by this sort of conceptualization, manding (Catania, 1998; Skinner, 1957) and instruction following (e.g., Catania, 1998) stand as other examples of higher-order operant classes. The creation of higher-order operants requires teaching a number of examples, or multiple-exemplar training. For instance, a series of different modeled actions could be presented, with a child's responses approximating those of the model shaped and reinforced in the presence of each. After teaching a number of such correspondences, children have come to show appropriate approximations when presented with novel model actions (e.g., Baer, Peterson, & Sherman, 1967; Poulson, Kymissis, Reeve, Andreatos, & Reeve, 1991). Naming and relational framing are similarly viewed as higher-order operants, created by training many specific examples that ultimately provide for the acquisition of a more generalized class of discriminated responding.

Naming Theory

Naming has been suggested (Horne & Lowe, 1996) as a technical term for a higher-order operant in which an individual engages in bidirectional speaker and listener behavior with respect to a given object or event. In one example, a child might see a shoe, tact "shoe" (either overtly or covertly), hear herself say "shoe," and then exhibit listener behavior occasioned by hearing herself say "shoe"—perhaps by orienting to the shoe or placing her foot in it. The complete cycle is necessary to satisfy the requirements for naming in this technical sense, and naming is viewed as the basic unit of verbal behavior. To establish the naming operant, each component of the cycle (e.g., listener responses, tact responses) needs to be directly taught (e.g., Horne et al., 2004; Lowe, Horne, Harris, & Randle, 2002), and with many different stimuli, or exemplars (e.g., shoes, dolls, dogs). Once fully established, however, the entire cycle could be initiated from any point (seeing the shoe and then saying "shoe," or hearing "shoe" and then looking for the shoe, thus meeting the bidirectional dimension of the definition), and the acquisition of new instances of naming would require teaching only one component of the cycle (e.g., teaching a child to select a new toy given a novel name would be sufficient to produce the full naming relation). Figure 19.29 illustrates that seeing any number of different shoes could occasion saying "Shoe," and that hearing "shoe" could occasion listener behavior toward a number of different shoes, which would then occasion saying "Shoe," and so on. Naming is thus viewed as classifying, so that any two or more items or events with the same name would be treated similarly; they would occasion the same tacts and thus the same listener behaviors (e.g., Horne, Hughes, & Lowe, 2006; Lowe, Horne, & Hughes, 2005). In this way, naming is seen as responsible for categorization, equivalence performances, and various forms of transfer of function (Horne & Lowe, 1996).

Of course, a large number of the EBI programs described so far involved names (e.g., Sidman, 1971; Sidman & Cresson, 1973), whether presented as auditory samples, as written samples or comparisons, or as responses, and certainly the data are clear that providing stimulus names can facilitate equivalence-class formation (e.g., Randell & Remington, 1999, 2013; Sprinkle & Miguel, 2012). Although such findings are consistent with naming theory, they are also consistent with Sidman's theoretical position that any term in a reinforcement contingency, including a class-consistent response such as a

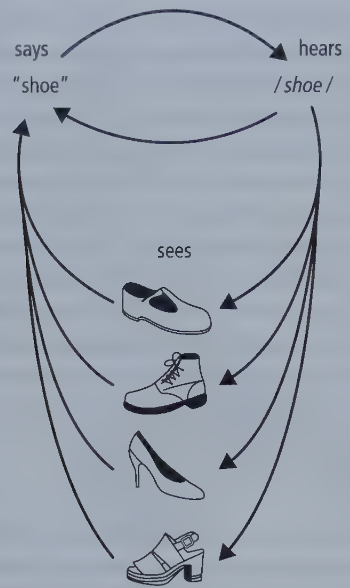

Figure 19.29 An illustration of the naming relation, where hearing "shoe" occasions listener behavior (e.g., orienting toward any of a number of different shoes), which in turn occasions tacting "shoe." The naming unit could be initiated from any point in the cycle.

From "On the Origins of Naming and Other Symbolic Behavior" by P.J. Horne and C.F. Lowe, 1996, Reproduced with permission of John Wiley & Sons Inc.

name, can become an equivalence-class member. Applications more unique to naming theory have sought to generate emergent performances with training procedures that target each of the individual components that constitute the complete naming unit. Indeed, well-developed protocols have been developed for teaching each of the listener and speaker skills involved (e.g., Horne & Lowe, 2000; Miguel & Petursdottir, 2009). Not surprisingly, the populations involved in these applications have been very young children or children with intellectual disabilities, for whom higher-order naming is not a part of the existing repertoire.

To illustrate, two studies compared the impact of listener training and tact training on the emergence of intraverbal responses involving a native language word and a second-language word (Petursdottir & Haflidadottir, 2009; Petursdottir, Olafsdottir, & Aradottir, 2008). A total of six typically developing 5-year-olds were involved. The stimuli included color photographs, native Icelandic words, and corresponding words from a different language (either Spanish or Italian). The children were able to name each picture in Icelandic at baseline, and training was conducted with two stimulus sets for each child. Two of the children received tact training only, two received listener training only, and two received each form of training for a different stimulus set. Tact training involved presenting a picture and teaching the child to produce its name orally in the second language. Listener training involved presenting three pictures and teaching the child to select the appropriate one when its second-language name was presented orally by the experimenter. Pretests and posttests presented each Icelandic word and asked the child to say its second-language name, and vice versa. Across the studies, both forms of training resulted in significant improvements from pretest to posttest, with tact training producing the greatest gains in emergent intraverbals (see also May, Downs, Marchant, & Dymond, 2016). Similar findings were obtained with a study of two 5-year-old children with autism (Grannan & Rehfeldt, 2012), in which pre- and post-intraverbal tests involved asking the child to produce the names of members of a category (e.g., body parts or vehicles). No correct responses were given on the pretests, but after listener and tact training, substantial improvements in intraverbal skills emerged.

Other studies have evaluated the impact of listener (Kobari-Wright & Miguel, 2014) and tact training (Miguel & Kobari-Wright, 2013) on categorization skills in young children with autism, a common target in many curricula designed for this population and one that frequently requires extended training. The training stimuli used here were nine cards picturing three examples of each of three categories of dogs (i.e., hound dogs, toy dogs, and working dogs). On each trial of the categorization test, a picture from a particular category was presented as a sample stimulus along with three additional pictures as comparisons, one from the same category and two from different categories. The categorization test was given twice before and twice following training; the second test of each pair also required the child to name the sample before the comparisons were presented. Accuracy was at approximately chance levels on the pretests, and training was then conducted with all nine cards. Each child received either listener training, in which she learned to select the correct picture from three comparisons when given its category name, or tact training, in which she was taught to produce the category name orally when shown a picture, or both if necessary. Of the four children who received listener training, three demonstrated near-perfect emergent performance on the category tests and also on posttraining tact tests. For the fourth, neither tact responses nor categorizations improved; when tact training was added, however, accuracy was perfect on the subsequent tests. Of the two children exposed to tact training first, both demonstrated accurate listener behavior and strong performance on the categorization tests, especially when a tact of the sample was also required on each test trial. Collectively, these data suggest that active tacting may be important for accurate categorization with this population, and that listener training alone can be insufficient for generation of tacting with some children. Similar results were obtained in a study with two young men with moderate intellectual disabilities and extremely limited vocal repertoires (Ribeiro, Elias, & Goyos, 2010) for whom signing was the targeted skill. During listener training, a video clip of each of six signs being performed was presented as the sample stimulus, along with three picture comparisons on each trial (AB training). After training, both men demonstrated emergent signing (tacting) and emergent manding with the same signs.

As a group, the studies described here illustrate an approach to producing novel performances that follows from the premises of naming theory. For certain participant populations, teaching critical components of the naming unit (i.e., listener behavior, tacting) can be effective in generating repertoires indicative of symbolic relations, classes, and categories.

Relational Frame Theory

In relational frame theory (RFT), framing is viewed as the key higher-order operant, and it is characterized as responding to one stimulus in terms of another (Hayes et al., 2001). RFT emphasizes that we learn many different types of relations in our lives (e.g., larger than, opposite of, different from), each of which can be considered a frame in that any pair of stimuli can function within it. Equivalence is thus just one of many frames (known as the *frame of coordination* in RFT terminology), although certainly an early and important one. As noted previously, framing is behavior and it must be taught; multiple-exemplar training is viewed as the basis for learning to frame. In a classic example, a mother might teach symmetry by engaging her child with a picture book. Mom could point to the picture of a dog, say "dog," and then ask, "Where's the dog?"—shaping, prompting, and reinforcing the child's pointing to the appropriate picture. This same interaction would unfold for many different pictures, with the child's symmetrical response directly trained in each case. Training with a number of exemplars allows for abstraction of the bidirectional relationship between names and pictures; this relation could then be applied to new examples without the need for further shaping, demonstrating emergent or derived relations, in RFT terms. To describe a performance as derived thus implies an active response on the part of the behaver—a relating or framing response that has been directly taught with many previously experienced exemplars. In the natural acquisition of many frames, early exemplars are likely to be characterized by real physical differences; for example, initial examples of "larger than" training are likely to involve pairs of stimuli in which one is physically greater in size than the other. Once abstraction of the "larger than" relation has been learned, however, it could be applied to novel stimulus pairs, including those for which the physical dimension of size is unimportant; for example, a learner could respond appropriately after being told that 7 is larger than 5, or that a dime is larger in value than a nickel.

Given the broad range of possible relations in our world, RFT introduces generic terms for the critical properties of framing. These include mutual entailment (e.g., if A is larger than B, then B is smaller than A; in equivalence relations, symmetry would be an example of mutual entailment); combinatorial entailment (e.g., if A is larger than B, and B is larger than C, then A is larger than C, and C is smaller than A; in equivalence relations, transitivity would be an example of combinatorial entailment); and transformation of function (e.g., if A is larger than B, and B is good, then A would be better; in equivalence relations, transfer of exactly the same function from one stimulus to another in its class would be an example). Also, given the number of relations possible, RFT emphasizes the critical role of contextual stimuli to indicate exactly which relation should be applied in any given instance. According to RFT, with the proper training history and given the appropriate contexts, frames can be combined in virtually limitless networks, providing for increasingly complex derived performances. Thus, framing is viewed as the basic behavioral unit not only of language but also of almost all complex cognitive functioning for humans. Indeed, at a conceptual level, RFT has been seen as relevant to domains ranging from the acquisition of basic relations (e.g., opposite, different) by young children to religion and spirituality (e.g., Barnes-Holmes, Hayes, & Gregg, 2001) to adult psychopathology and its treatment (especially in the form of Acceptance and Commitment Therapy; e.g., Hayes, Luoma, Bond, Masuda, & Lissis, 2006; Wilson, Hayes, Gregg, & Zettle, 2001).

In keeping with the breadth of the theory, applications of RFT have been varied with respect to targeted skills and participant populations. A few examples here must suffice for illustrating the focus on multiple-exemplar training and on emergent relational performances other than equivalence. (Because more than one relation is often targeted, RFT procedures can be a bit more complicated than many of those described thus far.) One early RFT application study (Berens & Hayes, 2007) asked whether multiple-exemplar training could establish a frame of comparison (more than and less than) with four typically developing 3- and 4-year-old girls who had low scores on pretests with this frame. For each test or training trial, either two or three pictures were presented (e.g., a smiley face, a lightning bolt, and a heart), and comparative relations between the stimuli were taught. For example, on a two-picture trial, the child might be told, "This (with a point to the smiley face) is more than that (with a point to the lightning bolt)." Next, the child was asked, "Which would you use to buy candy?" Probe tests were conducted with three different stimulus sets before training began and then after each phase of multiple-exemplar training. All training was conducted with a single stimulus set. The first training phase taught the "more than" relation with the same two pictures, and the picture designated as "more than" the other varied from trial to trial (i.e., A might be more than B on one trial, and B more than A on the next). Correct responses to the candy-buying question were reinforced across the repeated trials. The training thus provided multiple exemplars of the "more than" relation, and required control by the contextual stimulus ("more than") and the specifics of the instruction, as opposed to control by the physical properties of the actual stimuli involved. Subsequent training phases taught "less than" with two-stimulus trials, "more than" and "less than" with three-stimulus trials, and "more than" and "less than" in the same trial (e.g., "A is more than B, and C is less than B"). After the teaching steps were mastered, all four girls demonstrated emergent comparative relations with new stimulus sets. In many instances, accurate test performances were demonstrated on trial formats that hadn't yet been targeted in training. That is, performance on three-picture trials improved after training with two-picture trials, and performance on mixed-relation trials improved after the "more than" and "less than" relations were taught independently. In short, the multiple-exemplar training was successful in producing emergent performances, generalized across many different stimulus pairs and across test arrangements.

A similar approach was used to establish emergent manding for "more" or "less" in young children with autism (Murphy & Barnes-Holmes, 2009; Murphy, Barnes-Holmes, & Barnes-Holmes, 2005) and to generate derived tacting in a second language (Rosales, Rehfeldt, & Lovett, 2011). In the latter case, 3- to 4-year-old Spanish speakers were taught to select the appropriate picture when presented with its English name (i.e., listener training). When this failed to produce tacting in

English, additional listener training with multiple novel words was followed by tact training with the same words. This resulted in substantial improvements in emergent tacting with the original words after listener-training only, with evidence of maintenance for many of the tacts after 1 month. Results like these demonstrate the value of multiple-exemplar approaches for language training programs, where generalized or higher-order responding is especially important. Other interesting work with multiple-exemplar training has sought to establish generalized perspective-taking skills in both typically developing children and those with autism (e.g., Barnes-Holmes, McHugh, & Barnes-Holmes, 2004; Heagle & Rehfeldt, 2006). After teaching multiple instances of each relation, children have shown appropriate derived responses with new examples for relations of "I" as contrasted with "You," "Here" as contrasted with "There," and "Now" as contrasted with "Then" (Heagle & Rehfeldt, 2006), all thought to be critical components of the perspective taking that is necessary for more complex reasoning and for social skills (Barnes-Holmes, Hayes, Dymond, & O'Hara, 2001). Indeed, intensive multiple-exemplar training for four frames (same, opposite, more, and less) was reported to correlate with increased Wechsler Intelligence Scale for Children (4th ed.; WISC IV) scores (a common measure of intelligence quotient [IQ]) for fifteen 11- to 12-year-old typically developing children, and with increased scores on the Differential Aptitude Test (5th ed.) for 30 typically developing 15- to 17-year-olds (Cassidy, Roche, Colbert, Steward, & Grey, 2016), an intriguing outcome certainly worthy of further study.

With respect to adult participants, multiple-exemplar training approaches have been used successfully to establish rather complex mathematical skills (i.e., matching standard and factored forms of mathematical formulas with each other and with graphical representations of the formulas) in college students (e.g., Ninness et al., 2005), where the role of contextual stimuli (Ninness et al., 2006) and of multiple frames (same as and reciprocal of; Ninness et al., 2009) has also been demonstrated. Certainly these results add to those of studies on equivalence-based instruction for efficient approaches to teaching college-level academic content.

In another program of study, multiple-exemplar training has been utilized to impact the behavior of recreational and pathological gamblers (e.g., Dixon & Holton, 2009; Hoon, Dymond, Jackson, & Dixon, 2007, 2008; Zlomke & Dixon, 2006). To illustrate, five pathological gamblers completed delay discounting tests in which a series of choices were made between an amount of money to be delivered now and an amount to be delivered at some future time (e.g., a choice between $500 today and $700 in 12 weeks). Past studies have established strong reliability for the discounting task (e.g., Lagorio & Madden, 2005) and have shown that delayed consequences hold less value for gamblers than for nongamblers; that is, gamblers show a greater degree of discounting (e.g., Dixon, Jacobs, & Sanders, 2006). In the present study, the discounting task was presented with the smaller, sooner choice always shown in purple and the larger, later choice shown in pink. Multiple-exemplar training was then conducted in a match-to-sample format as follows. On each training trial, either a pink or a purple square was presented as a contextual stimulus, followed by a sample stimulus and three comparisons from the A stimulus set illustrated in Figure 19.30. When the purple context was presented, selecting the comparison

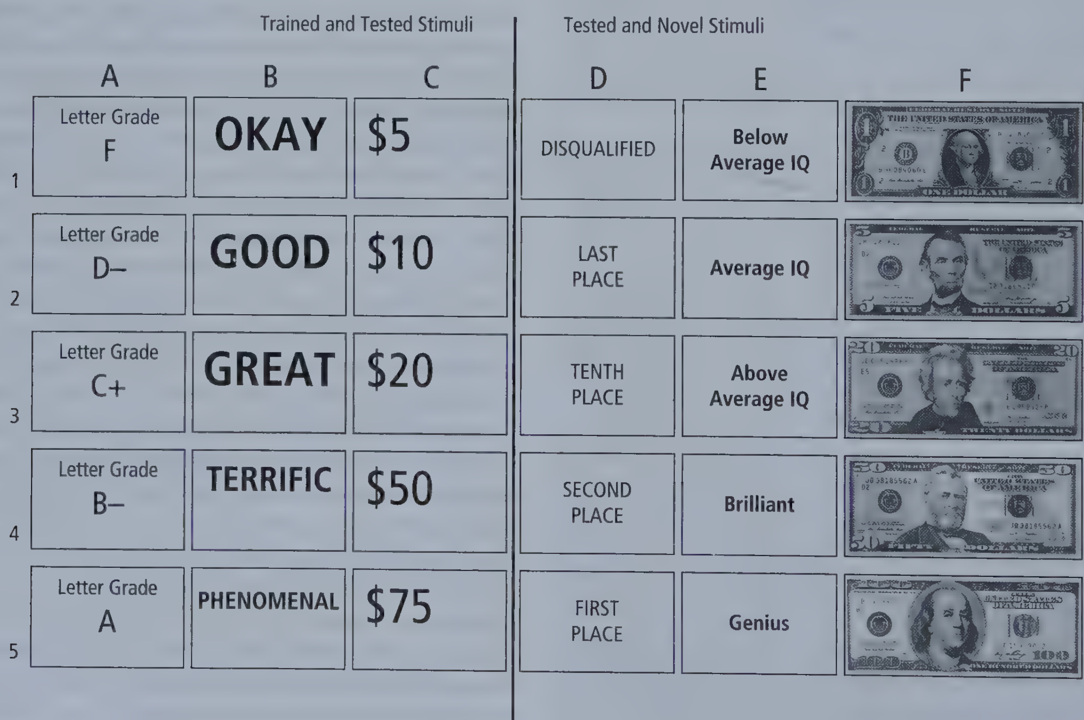

Figure 19.30 Stimulus sets used in multiple-exemplar conditional discrimination training.
From "Altering the Magnitude of Delay Discounting by Pathological Gamblers" by M.R. Dixon and B. Holton, 2009, Reproduced with permission of John Wiley & Sons Inc.

that was worse than the sample produced a reinforcer (e.g., given C+ as the sample, selecting D− rather than B− or A); when the pink context was presented, selecting the comparison that was better than the sample produced a reinforcer (e.g., given C− as the sample, selecting B− rather than D− or F). Next, training trials were conducted with stimuli from Sets A, B, and C (i.e., multiple-exemplar training), and then trials from Sets A to F were presented with no consequences, to assess control by the contextual stimuli with novel stimuli. Test performances confirmed that the purple context controlled selections of the "worse than" comparison, while the pink context controlled selections of the "better than" choice. When the discounting task was repeated as a posttest, all five participants demonstrated a substantial shift in their discounting, such that the smaller, sooner choices shown in purple were selected far less often than on the pretest. In short, the reliable discounting outcome was changed dramatically by simple stimulus cues, the function of which had been established via a brief multiple-exemplar teaching program with "better" and "worse" relational frames. These results are worthy of follow-up given their implications for the development of assessments as well as possible interventions with this clinical population.

To sum, the studies described in this section emphasize an approach to generating novel symbolic behavior that reflects the tenets of relational frame theory. Ample evidence shows that multiple-exemplar training can help to establish the sorts of generalized or higher-order forms of responding that contribute to complex symbolic skills.

CONCLUDING REMARKS

This chapter has presented a case for equivalence-based instruction as one of the most exciting directions in research and practice in applied behavior analysis. Indeed, the powerful generativity of an equivalence approach, demonstrated repeatedly across participant populations, procedures, settings, and stimulus sets, demands the attention of practitioners, applied scientists, basic laboratory scientists, and conceptual theorists alike, and ensures the sort of ongoing translational effort that characterizes the best of behavior analysis. The pattern of work to date suggests that ever more effective and efficient equivalence protocols will continue to emerge, as scientists learn to combine critical features of the most successful programs. There can be little doubt that the studies described and reviewed in this chapter represent only the tip of the proverbial iceberg in terms of what might be accomplished with EBI approaches.

SUMMARY

Research Foundations and Core Concepts

1. Stimulus equivalence describes a behavior analytic approach to understanding and establishing symbolic function. Our field's interest in the equivalence phenomenon can be traced back to early work by Sidman (1971; Sidman & Cresson, 1973) on reading comprehension.

2. Arbitrary match-to-sample procedures are commonly used in equivalence studies to teach the necessary baseline performances and to test for emergent (or untrained) ones. Arbitrary match-to-sample training involves a discrete-trial four-term contingency arrangement with physically dissimilar stimuli. A trial begins with the presentation of a sample stimulus (e.g., A1 or A2); an observing response to the sample produces two or more comparison stimuli (e.g., B1 and B2). Selection of the comparison designated as correct for that sample results in a reinforcer, while selection of any other comparison does not. Arbitrary match-to-sample training produces conditional discriminations, in which discrimination between the comparison stimuli is conditional on the sample presented (e.g., given an A1 sample, choosing B1; given an A2 sample, choosing B2).

3. After teaching two interrelated conditional discriminations (e.g., AB and BC), probe trials are presented to test for emergence of the untrained relations that define equivalence. There are no programmed consequences for probe trials; thus, consistent patterns of responding on these trial types are described as emergent or derived. The critical probe types include:
   - *reflexivity tests*, that is, tests for generalized identity matching with all training stimuli, or AA, BB, and CC; in mathematical set theory, reflexivity is defined as A = A.
   - *symmetry tests* for the reversibility of sample and comparison functions, or BA and CB; in mathematical set theory, symmetry is defined as, If A = B, then B = A.
   - *transitivity tests* for relations between stimuli that were never presented together during training but that share a trained relation with a nodal stimulus, or AC; in mathematical set theory, transitivity is defined as, If A = B, and B = C, then A = C.
   - *combined or equivalence tests* in which both symmetry and transitivity are evaluated simultaneously, or CA.

4. Positive outcomes on all probe types document interchangeability among a given group of stimuli and allow the conclusion that an equivalence class has formed. That is, responses on reflexivity, symmetry, and transitivity or equivalence trials show that any member of the class can serve effectively as sample or as comparison with any other class member. The equivalence class consists of all such interchangeable stimuli (e.g., A, B, and C, in this example).

5. The equivalence outcome is significant because:
   - Many stimulus relations are generated after teaching only a small number (i.e., there is an impressive "bang

for your buck" effect). This generativity carries tremendous implications for behavioral applications.

- The defining criteria for equivalence provide a compelling operational definition of symbolic function, and make possible a behavioral analysis of a range of complex human performances (e.g., categorization, semantic correspondence, creativity).

6. The literature on stimulus equivalence is characterized by a true translational approach. Advances in our understanding and application of equivalence have resulted from a necessary and continuing interplay between basic laboratory research, applied behavior analysis, and conceptual developments.

7. Several key outcomes of equivalence approaches have contributed to the effectiveness of EBI programs in important ways. These include:
   - ***class formation***—typically measured as the percentage of probe trials on which a comparison selection is consistent with equivalence, for each defining probe type. Such measures are often compared in a pretest, train, posttest design, or in a multiple baseline across stimulus sets experimental design.
   - ***delayed emergence***—a relatively common observation in which equivalence performances grow stronger with repeated testing.
   - ***class expansion***—increasing the size of an established equivalence class to include an additional member or members. This is typically accomplished by teaching a new relation between a novel stimulus and an established class member. Class expansion is verified by emergent relations between the novel stimulus and the rest of the established class members.
   - ***class merger***—a combining of independent equivalence classes such that a larger class is established. This is typically accomplished by teaching a new relation between one member of each of the classes to be combined. Class merger is verified by emergent relations between the other stimuli from the formerly independent classes.
   - ***transfer of function***—the finding that teaching a new function for one member of an established equivalence class results in the same function holding for all members of the class.
   - ***contextual control***—stimulus control requiring three levels of antecedent stimuli, such that the functions of the stimuli in a conditional discrimination vary depending on the context. Contextual control training requires a five-term contingency. It allows for the same stimuli to be members of more than one equivalence class, depending on the context.

Designing Equivalence-based Instruction

8. A number of procedural variables have proven important for the successful generation of equivalence classes, and for prevention of problematic stimulus-control patterns that could compete with demonstrations of class formation. These variables are considered in the context of making decisions about training and testing procedures.

9. In planning match-to-sample training procedures, critical decisions will include the number and type of stimuli to be used, the mode of stimulus presentation, inclusion and type of observing response, content of the instructions to be presented, the approach to balanced trial presentations, the necessity of special training steps, the type of training structure to be used, the mastery criteria for training steps, and the arrangement of consequences for training trials.

10. In planning the testing protocol, critical decisions will include the composition of the probe-trial blocks, the arrangement of consequences within the probe-trial blocks, the order of probe-type presentation, and the criteria to be used for judging class formation.

11. In addition to the standard match-to-sample training and testing approach to equivalence, several effective procedural variations have been identified that may carry benefits for particular populations or for certain EBI targets. These include:
    - ***stimulus compounds***—when a two-part stimulus (e.g., a word presented together with a picture) is presented as the sample in a MTS procedure, for example, each element of the compound can come to function as an independent equivalence-class member, thus increasing the size of the class created by a given amount of training.
    - ***class-specific reinforcement***—providing a unique reinforcer for discriminated responses as a function of the antecedent's intended class (e.g., in match-to-sample training, choosing B1 given A1 would produce Reinforcer 1, while choosing B2 given A2 would produce Reinforcer 2). Class-specific reinforcers can function as members of an equivalence class, again increasing the size of the class made possible by a given amount of training.
    - ***three-term contingency training***—simple discrimination training is mastered more easily than conditional discrimination training by some learners, and can produce equivalence-class formation.

Applications and Generality

12. The generality of the equivalence outcome has been repeatedly confirmed and extended by creative applications of EBI across populations, settings, and instructional targets.

13. Work with children and adults with intellectual disabilities, as well as young typically developing children, represents the largest category of EBI applications. Targets have included language- and number-skills instruction, as well as other types of functional skills (e.g., music, academic content, Braille reading).

14. Important work with adult clinical populations includes examples with health-related behaviors and skills impacted by brain injury; investigations in the field of gerontology are also being explored.

15. Equivalence-based instruction targeting university course content has had promising results across a range of subject matters and modes of presentation.

Applications Stemming from Alternative Theoretical Approaches to Relational Responding

16. Naming theory and relational frame theory (RFT) provide differing accounts of the basis for novel relational responding. Both emphasize that novel responding is due to a special learning history, rather than a direct outcome of a reinforcement contingency (as in Sidman's view). Naming Theory and RFT differ, however, with respect to the nature of the learning history that is required. These differences give rise to unique applications for generating emergent or derived responding.

17. For naming theory, naming is a technical term for a bidirectional higher-order unit of speaker and listener behavior that is seen as responsible for any form of classifying, including equivalence performances. Following from this view, applications designed to promote equivalence include instruction in the components of naming—listener behavior and tacting. For participants lacking these skills, targeting them directly can be effective in producing response patterns indicative of classes and categories.

18. For RFT, framing, or responding to one stimulus in terms of another, is the key higher-order operant. It is established by teaching many different examples of a given relation, which allows for abstraction and then application of the relation to new examples, given the proper context. RFT emphasizes that equivalence is just one example of the many relations we learn in this manner. Following from this view, applications designed to promote novel, or derived, relational responding feature multiple-exemplar training as the key instructional approach. A range of examples has provided evidence for the production of generalized response patterns that can contribute to complex symbolic skills.

KEY TERMS

class expansion
class merger
class-specific reinforcement
conditional discrimination
contextual control
derived stimulus relations
emergent stimulus relations
equivalence-class formation
equivalence test
exclusion
higher-order operant class
matching-to-sample procedure
nodal stimulus (node)
reflexivity
simple discrimination
simple-to-complex testing protocol
stimulus-control topographies
stimulus equivalence
symmetry
training structure
transfer of function
transitivity

MULTIPLE-CHOICE QUESTIONS

1. Interchangeability of function can be assessed by
   - **a.** Reflexivity
   - **b.** Symmetry
   - **c.** Transitivity
   - **d.** All of the above

   Hint: (See "Transfer of Function")

2. In simple-to-complex testing protocol, probe types are introduced sequentially
   - **a.** Beginning with symmetry followed by transitivity
   - **b.** Beginning with transitivity followed by symmetry
   - **c.** Beginning with reflexivity followed by transitivity
   - **d.** Beginning with reflexivity followed by symmetry

   Hint: (See "Test Order")

3. Which of them is a critical property of framing as proposed in relational frame theory?
   - **a.** Mutual entailment
   - **b.** Transformation of function
   - **c.** Combinational entailment
   - **d.** All of the above

   Hint: (See "Relational Frame Theory")

4. In the study by Sidman, 1971; Sidman & Cresson, 1973, three member equivalence classes (________ , ________, written word), can be increased to include a potentially ________ number of members based on class ________and class ________.
   - **a.** Spoken word, picture, unlimited, expansion and merger
   - **b.** Touch, sound, unlimited, contraction and demerger

c. Touch, sound, limited, contraction and merger

d. Spoken word, picture, limited, expansion and demerger

Hint: (See "Class Expansion and Class Merger")

5. In the EBI program designed by Fineup, Covey and Critchfield (2010), to document five-member classes, how many subsets were used?

a. 16 subsets produced 80 different stimulus relations in 15 minutes

b. 80 subsets produced 16 different stimulus relations in 15 minutes

c. 80 subsets produced 15 different stimulus relations in 25 minutes

d. 15 subsets produced 80 different stimulus relations in 25 minutes

Hint: (See "In the College Classroom")

6. Methods used for presenting probe trials is/are:

a. Massed Testing

b. Interspersing

c. Both of the above

d. None of the above

Hint: (See "Composition of Probe-trials Blocks")

7. Component Simple Discriminations training approach is based on the recognition that accurate conditional discrimination performances require:

a. Conditional control by the sample

b. Successive discrimination between the sample stimuli

c. Simultaneous discrimination between the comparison stimuli

d. All of the above

Hint: (See "Instructional Programming")

ESSAY-TYPE QUESTIONS

1. Describe the training structures used in equivalence-based instructions.

   Hint: (See "Training Structures")

2. Define higher-order operants with an example.

   Hint: (See "Applications Stemming from Alternative Theoretical Approaches to Relational Responding")

3. Discuss transfer of function. Elaborate on the negative impact of equivalence-class formation on an individual's functioning.

   Hint: (See "Transfer of Function")

NOTES

1. As we will see in the section on Relational Frame Theory, equating these terms can be problematic, because the latter carries important theoretical implications about the basis for responding. Thus, "emergent performances" is often preferred as a theory-neutral description.
2. Exemplary experimental analyses of the complex behavior patterns mentioned have been conducted by Augustson and Dougher, 1997; Augustson, Dougher, and Markham, 2000; Challies, Hunt, Garry, and Harper, 2011; Dougher, Augustson, Markham, Wulfert, and Greenway, 1994; Griffee and Dougher, 2002; Guinther and Dougher, 2010; Hayes, Thompson, and Hayes, 1989; Kohlenberg, Hayes, and Hayes, 1991; Moxon, Keenan, and Hine, 1993; and Watt, Keenan, Barnes, and Cairns, 1991.
3. EBI typically targets at least three classes. The example here is simplified for illustrative purposes.
4. With many populations, probes for reflexivity are omitted, primarily because identity matching can be assumed and is likely the result of experiences prior to the EBI training.

CHAPTER 20

Engineering Emergent Learning with Nonequivalence Relations

Thomas S. Critchfield and Ruth Anne Rehfeldt

LEARNING OBJECTIVES

- Understand what nonequivalence relations are and why do they matter.
- Discuss the vocabulary of nonequivalence relations.
- Explain some types of nonequivalence relations.
- Discuss the theoretical foundations of nonequivalence relations.
- Understand the connections between nonequivalence relations and psychological constructs: knowledge structures, self-concept, and intellectual development.
- Understand the connection between derived stimulus relations and general well-being.

Chapter 19 explained how equivalence ("sameness") relations[1] function and how they can be harnessed to generate valuable new learning. But equivalence is only one beast in a menagerie of ways in which stimuli can be symbolically and behaviorally linked. **Nonequivalence relations**—those in which stimuli are related on some basis other than "sameness"—are a big part of how people make sense of, and function effectively in, the world around them. We believe, therefore, that every behavior analyst needs a solid working understanding, and mastery, of both the general concept of stimulus relations and the specific domain of nonequivalence relations (e.g., Critchfield, 2018; Critchfield, Barnes-Holmes, & Dougher, 2018).

Our discussion of nonequivalence relations is intended to complement Chapter 19's discussion of equivalence relations. To properly understand nonequivalence relations, you need grounding in stimulus relations generally. By mastering the conceptual foundations of equivalence relations and the procedures that have been used to establish them, you prepare yourself to benefit from the present chapter.

This chapter is divided into six sections. The first section explains generally what nonequivalence relations are and why they matter. The second section presents basic vocabulary for talking about nonequivalence relations and phenomena associated with them. This is necessary because the vocabulary of equivalence relations is not always adequate for describing nonequivalence relations. The third section describes selected types of nonequivalence relations and illustrates their everyday importance. The fourth section introduces key theoretical concepts relevant to nonequivalence relations. The fifth section discusses the role of nonequivalence relations in big-picture psychological constructs that often are of interest in the practical world. The final section explains how derived stimulus relations, including nonequivalence relations, provide a basis for enhancing general well-being in ways that are quite different from what is typical in applied behavior analysis (ABA).

Although this chapter highlights many opportunities to incorporate nonequivalence relations into applied interventions, we will say little about practical tactics of implementation, for two reasons. First, because the behavioral repertoires of interest can be complex, procedures for creating them often are as well. Before developing protocols to teach nonequivalence relations, the interested student may need to digest other sources that provide the required detail (e.g., Rehfeldt & Barnes-Holmes, 2009). Doing so, however, requires conceptual skills that develop with practice. Thinking about derived stimulus relations is a detail-heavy logical process that does not come naturally to many people, and the present chapter is an introduction to this process. Second, in many respects the mechanics of building equivalence relations, as discussed in Chapter 19, also apply to the construction of

➠The authors thank Bryan Roche, Dan Fienup, and Daniel Assaz for providing helpful feedback on a draft of this chapter.

nonequivalence relations (e.g., Luciano et al., 2009). For example, both depend on directly teaching baseline relations consisting of overlapping conditional discriminations. In both cases, baseline relations must be learned before untaught relations can arise, and two stimulus classes with a shared member can merge to form a larger class—and so forth. Chapter 19 is a guide to these basics, and the present chapter builds on it by expanding the range of derived stimulus relations that can be the focus of intervention.

WHAT ARE NONEQUIVALENCE RELATIONS? WHY DO THEY MATTER?

To explain nonequivalence relations, we'll begin by expanding on a general point from Chapter 19: Most stimulus relations are **arbitrary relations** (Hayes, Fox, et al., 2001), stimuli that "go together" not because they are physically identical or because a law of the universe demands this, but rather because social-verbal reinforcement contingencies teach people to relate them in a certain way. Building on an example presented in Figure 19.7, there is no inherent reason that a token exchangeable for goods and services has to be called a *dime*, to be a disk of silver-colored metal, or to have its value represented with "10¢." Humans have arbitrarily created these symbols and the relations among them (such as the equivalence class in Figure 19.7). Had the token been a lump of pink salt and been called *armadillo*, for instance, the equivalence class in Figure 19.7 would look different but function the same.

Because relations among stimuli are arbitrary, the variety of possible relations is limited only by the repertoires and experiences of humans. People create all kinds of symbols and devise many different ways to compare and contrast them. How they do this is a core feature of how they understand the world, as each bit of the world is given meaning through the other bits of the world to which a person's experiences connect it. Consider the word *beer*, which is an arbitrary printed symbol for a particular beverage. The behavioral functions of *beer* are many and nuanced. To get a sense of this, think about what *beer* means to you by answering the questions below (adapted from Barnes-Holmes, Hayes, Dymond, & O'Hora, 2001):

- What are other names for beer?
- What are the attributes of beer?
- What is beer composed of?
- What is beer similar to?
- Where is beer found?
- What is beer different from?
- What is beer an example of?
- What does beer include?
- What is beer better than?
- What does beer do?
- What came before beer?

Notice that all of these questions demand an active response; how you understand *beer* is evident in how you respond to it. Notice, too, that all of the required responses involve relating the target word to something else. The behavioral functions of *beer* are inherent in the things to which people relate it.

Figure 20.1 provides a few sample answers to the *beer* questions. The resulting diagram is reminiscent of the cognitive psychology concept of a *semantic network*, a hypothetical construct intended to model how bits of knowledge are organized in long-term memory.[2] Based on studies using a variety of methods (such as free association, in which people are presented with a word and asked for the first word that comes to mind), many cognitive researchers have concluded that bits of stored knowledge connect to one another through shared meaning (e.g., Collins & Loftus, 1975).

The semantic network construct is worth mentioning partly because it predates the earliest research by behavior analysts on derived stimulus relations (Sidman, 1971), and thus psychologists outside of behavior analysis tend to be familiar with it. Also, despite the fact that behavioral psychology and cognitive psychology are often portrayed as intellectual archenemies (Uttal, 2000), the semantic network construct incorporates at least three observations with which behavior analysts agree (see Hayes, Barnes-Holmes, & Roche, 2001; Reese, 1968; Sidman, 1994). First, as Figure 20.1 suggests, people relate various "bits of the world" in a *lot* of different ways. Second, the relationships of interest are forged through experience, such that each individual will have a relational network as unique as her learning history. Third, the relationships of interest are, in essence, the fundamental units of *meaning*, because no "bit of the world" is understood separately from its connection to others. A person with no *beer* experiences cannot answer any of the questions listed above. That person does not know the meaning of *beer*.

Behavior analysts believe they have improved on the semantic network concept in two ways. First, cognitive psychologists assume that "bits of knowledge" and the relationships among them are somehow represented (stored) inside the brain (Collins & Loftus, 1975). Behavior analysts say instead that each of us learns various ways of responding to stimuli like *beer*, and two stimuli are related if the way we respond to them is in some way intertwined (Critchfield et al., 2018; Reese, 1968). This is a network of behavior, not of knowledge.[3] Second, although most observers agree that relational networks arise from individual experience, cognitive psychologists have devoted more effort to describing the characteristics of already-formed networks than to understanding their formative experiences. By contrast, behavior analysts have typically tried to understand relational networks by studying their acquisition (Zentall, Galizio, & Critchfield, 2002). Because applied interventions exist to engineer changes in behavior, this approach, which focuses on experiences that create relational networks, is more informative than one that seeks to describe the features of relational networks that are the product of unspecified prior learning (Critchfield & Fienup, 2008).

As Chapter 19 explained, stimuli in the relational networks called equivalence classes are united by "same as" relations. For instance, *beer* has several synonyms (e.g., *cold one*, *brewski*, and *draft*) and together these stimuli may form an equivalence class. As Figure 20.1 indicated, however, *beer* can be important in many ways other than what it *is*. In fact, one can fully understand *beer* only by knowing what it is not, what it is similar (but not identical) to, what it's an exemplar of, what kinds of beer exist, and so on. This is the essence of nonequivalence relations.

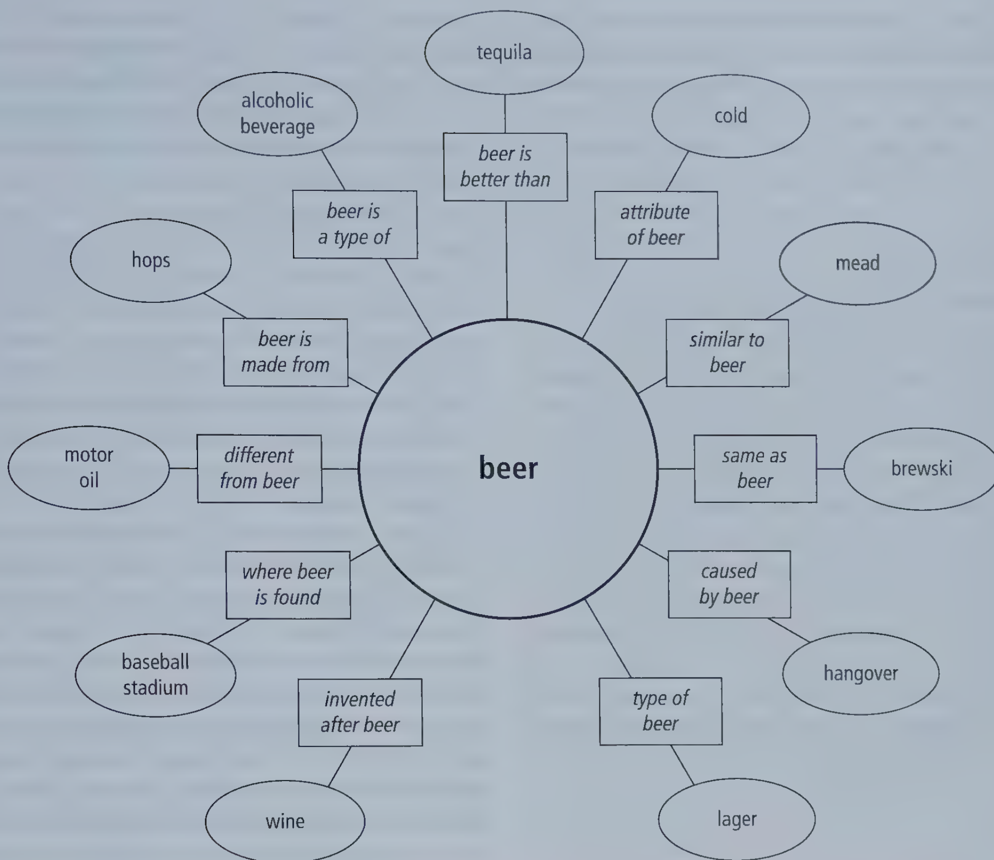

Figure 20.1 A variety of things to which *beer* is related, illustrating the wide variety of stimulus relations. Except for the "same as" example, all are nonequivalence relations.

In distinguishing nonequivalence relations from equivalence relations, it is important to note that the former sometimes have been included in behavioral research without proper acknowledgment. Figure 20.2 illustrates by reference to a study in which college students learned neuroanatomy concepts (Fienup, Covey, & Critchfield, 2010). As part of the lesson, students saw the term *frontal lobe* as sample stimulus and, from several pictures of brains, learned to select the one on which the frontal lobe was indicated by an arrow. With *frontal lobe* as the sample stimulus, the students also learned to select *impulsiveness* from among several alternatives as a symptom caused by damage to this lobe. The lesson was described as *equivalence-based* instruction, but it did not really involve "same as" relations. Rather, it involved a spatial relation (where the brain structure called *frontal lobe* is located) and a causal relation (what symptom is produced by damage to the brain structure called *frontal lobe*).

In one sense, it doesn't matter what Fienup and colleagues called the stimulus relations in Figure 20.2, because their students both mastered what was directly taught and demonstrated untaught relations (e.g., when shown the location of the frontal lobe, they could indicate that *impulsiveness* was caused by damage to that area). This was possible because the match-to-sample procedures used in the study gave students limited options for how to respond, so they chose comparison stimuli that were related to the sample in *some* fashion.[4] Difficulties might have arisen in a different kind of test. For instance, imagine that the students were shown a picture of the frontal lobe and asked to say its name. A student who answered *impulsiveness* (treating the brain picture, *frontal lobe*, and *impulsiveness* as "the same") would get the question wrong. What a person "needs to know," therefore, depends on

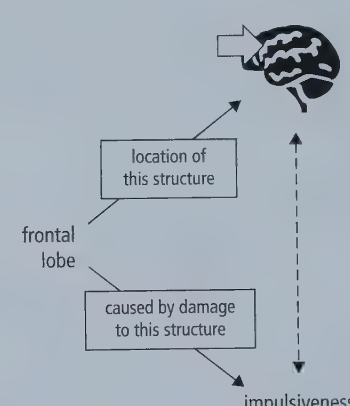

Figure 20.2 A neuroanatomy stimulus class that was established in college students. The published report called this an equivalence class, but it is more accurately described as a nonequivalence class.

Based on Figures 1 and 4 of "Teaching Brain-Behavior Relations Economically with Stimulus Equivalence Technology," by D. M. Fienup, D. P. Covey, and T. S. Critchfield, 2010, *Journal of Applied Behavior Analysis*, *43*, 19–33.

contingencies of reinforcement that often involve nonequivalence relations (for more on this, see the "Theoretical Foundations" section). In fact, nonequivalence relations appear to be at the root of many abilities thought of as representing "deep understanding," "higher thought," or "complex cognition" (Hayes et al., 2001), a point on which we will comment later.

THE VOCABULARY OF NONEQUIVALENCE RELATIONS

Much of the vocabulary coined to describe equivalence relations is too narrow to describe nonequivalence relations, so more inclusive alternatives have been proposed (Hayes, Fox, et al., 2001). Recall from Chapter 19 that stimulus equivalence classes are defined by relations of "sameness." Two emergent manifestations of "sameness," *symmetry* and *transitivity* (Sidman, 1994; see also Chapter 19),[5] are illustrated in the top left panel of Figure 20.3 as part of how three words (*overdue*, *tardy*, and *late*) come to "mean the same thing" and are treated by a learner as interchangeable. By *emergent* we mean relational responding that experience does not directly teach, but that arises as an indirect function of experience (Chapter 18 similarly referred to *generative* effects). Emergent relations also are called **derived relations**, and this is the term we will use moving forward.

Entailment

Symmetry is when, after learning to respond to stimulus B as if it were stimulus A, a learner spontaneously can do the reverse. Symmetry implies mutual "sameness." For example, in the top left panel of Figure 20.3, a learner who is shown *overdue* and taught to identify *tardy* as "the same" should also be able to identify *overdue* as "the same" when given *tardy*. Now consider the nonequivalence relation shown in the top right panel of Figure 20.3. A learner is shown *early* and taught to identify *tardy* as "opposite." The reverse of this directly taught relation is expected to emerge spontaneously: Shown *tardy*, the learner should be able to spontaneously identify *early* as "opposite." Because not all derived relations involve "same," the reverse of a learned relation can be of a different type than the learned relation. For instance, if a learned relation is that *25¢* is "more than" *10¢*, the reverse relation will be that *10¢* is "less than" *25¢*. The more general term **mutual entailment** applies to any derived bidirectional relation in which one "direction" has been directly learned (Hayes, Fox, et al., 2001).[6] Symmetry is a special case of mutual entailment, but not all mutual entailment is symmetry.

Transitivity is when a learner can spontaneously treat two stimuli as interchangeable ("same") because they are related indirectly through "sameness" with a common third stimulus. In the top left panel of Figure 20.3, a learner who is shown *tardy* should be able to spontaneously identify *late* as "the same," and vice versa. Now consider the nonequivalence relation in the top right panel of Figure 20.3. The derived relation between *tardy* and *late* ("same") is different from that between these words and their common associate, *early* ("opposite"). *Tardy* and *late* qualify as "same"—but not because they are both "the same" as a common third stimulus. Rather, in a case of "the enemy of my enemy is my friend," *tardy* and *late* both are opposites of the same word. The general term *combinatorial entailment* applies to any derived relation involving stimuli that are "linked"

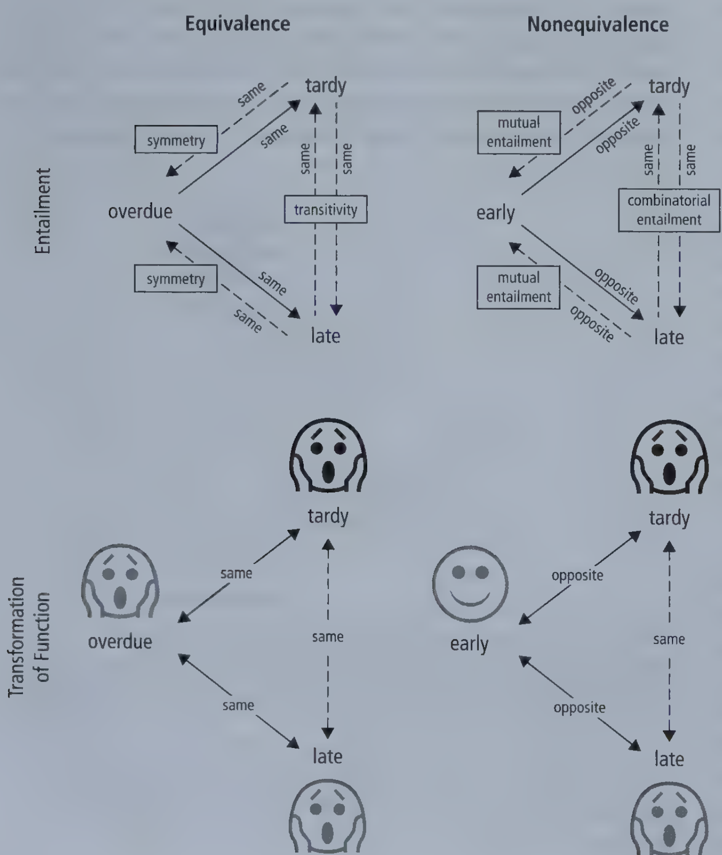

Figure 20.3 Relationships between terms used to describe derived relations in equivalence and nonequivalence stimulus classes. Top: Mutual entailment and combinatorial entailment as replacements for symmetry and transitivity, respectively. Bottom: Transformation of function as replacement for transfer of function. Emoticons represent emotion functions (fear and happiness); those in black are acquired through direct experience and those in gray are the result of transformation of function.

via common associates (Hayes, Fox, et al., 2001). To be more precise, **combinatorial entailment** is the relation involving two stimuli that both participate in mutual entailment with some common third stimulus. Transitivity is a special case of combinatorial entailment, but not all combinatorial entailment is transitivity.

Transformation of Function

Another defining feature of equivalence classes, as described in Chapter 19, is *transfer of function*. Chapter 19 noted that equivalent stimuli come to function in the same manner (control the same responses), and this applies to any new behavioral function acquired by any of the stimuli in a class. For instance, Dougher and colleagues showed that when classical conditioning made one stimulus in an equivalence class fear-eliciting, all of the other stimuli in the class became fear-eliciting as well (Dougher, Augustson, Markham, Greenway, & Wulfert, 1994; see also Dymond, Schlund, Roche, & Whelan, 2014). The bottom left panel of Figure 20.3 illustrates this effect. Imagine that a sensitive student is one day harshly reprimanded for being *tardy* to class. This scares her and makes the word *tardy* a fear-eliciting stimulus. If *tardy* is part of the equivalence class shown in Figure 20.3, then words like *overdue* and *late* will also come to elicit fear. "Transfer" of function in this case is the propagation of a single behavioral function across stimuli that are "the same" (an equivalence class).

Now consider the nonequivalence class in the bottom right panel of Figure 20.3. When *tardy* becomes fear-eliciting, so does *late*, which is "the same" as *tardy*. But it would be illogical to expect *early*, the "opposite" of *tardy*, to become fear-eliciting, and research in fact suggests it should not (e.g., Dymond & Barnes, 1995, 1996). In this example, *early* now elicits pleasant responses that are "opposite" to fear. Thus, the function of *tardy* does not "transfer" to *early* but, within the constraints of the relation that unites *tardy* and *early*, it does influence the new function that *early* acquires. The general term that subsumes these kinds of effects is **transformation of function**, which can be defined as the behavioral function of one stimulus changing systematically due to the change in function of another stimulus in the same class (Hayes, Fox, et al., 2001). The transfer of function seen in equivalence classes is a special case of transformation of function, but not all transformation of function is transfer of function.

The critical thing about transformation of function, as illustrated in Figure 20.3, is that, for a given stimulus, alteration of behavioral function will be consistent with the type of relation that unites the stimulus with others. This incorporates many possibilities, including that stimuli *not* united via "same" relations can all acquire the "same" behavioral function, just as happens in equivalence classes. Box 20.1 describes an example. Note that the stimuli in this example are related temporally, and there is nothing inconsistent in responding the "same" way to stimuli regardless of whether they happen "before" or "after."

BOX 20.1

Transformation of Function in a Nonequivalence Class: A Clinical Example

Shawn was a high school student diagnosed with "school phobia." He was rather shy and did not like public attention, but had always enjoyed going to school—until one day a teacher lost her temper and began shouting at him. This frightened Shawn and humiliated him in front of the whole class. In a likely example of classical conditioning, Shawn began to fear his teacher. It was the shouting that had frightened him, but now just glimpsing the teacher upon entering the classroom was enough to cause him to shake and perspire and feel an awful tightness in the pit of his stomach.

Soon, without any additional unpleasant experiences, Shawn also began to fear the classroom itself. Just viewing the other students in their desks from the hallway—even if the teacher was not present—caused Shawn to experience the same unpleasant symptoms. Over time the symptoms were caused as well by seeing the outside of the school building; by seeing the school's sign at the start of a long, curvy drive that led up to the school building; and by hearing the sound of the bus that brought Shawn to school. Before long, Shawn was refusing school entirely, including by leaving the house early in the morning to hide in the neighborhood until after his bus had departed for school. Note that this is not a case of stimulus generalization, involving shared behavioral functions among stimuli that are physically alike (Chapters 17 and 30). The stimuli Shawn feared are as dissimilar as can be. This probably also is not a case of higher-order classical conditioning (in which a neutral stimulus, having been paired with a conditioned stimulus, can elicit the same response as the conditioned stimulus); responding based on this kind of conditioned stimulus tends to be unreliable (Kehoe & Macrae, 1998).

Figure 20.4 summarizes how the stimuli were temporally related in Shawn's experience of typical school mornings. First, Shawn heard the bus approaching his bus stop. The bus picked him up and traveled past the school sign and up to the front of the school building, where Shawn disembarked and proceeded to his classroom. Finally, he entered the classroom and encountered the scary teacher. The various stimuli, therefore, we related in a temporal hierarchy involving what "happens before" and what "happens after."

Shawn's condition likely resulted from the stimuli in the temporal hierarchy being transformed, through direct or indirect association with the scary teacher, to elicit fear. This temporal hierarchy is not an equivalence class. The bus, for instance, isn't the "same as" the teacher, because normally we do not respond in the same way to buses and teachers (we speak to teachers and ride on buses; confusing these behavioral functions would be awkward, to say the least).

How stimuli in a class are functionally transformed depends on the nature of the stimulus relations the class incorporates. In Shawn's case, nothing in the temporal hierarchy

conflicts with a behavioral function of fear. You can be equally afraid of things that "happen before" and "happen after," and so all of the stimuli acquire the same function. But other kinds of relations create other kinds of function transformations. For example, imagine that posted right next to the Sidman High School sign was a second sign indicating the way back to Shawn's home. The two signs would be related as opposites (discussed further in the next section). One is about getting from home to school, and the other is about getting from school to home. Within this relation of opposites, you cannot fear both stimuli. Rather, to remain consistent with the underlying relation of opposites and the learning history that created it, if you fear one sign, then in the presence of the other you should feel the opposite of fear (approach? joy?). The general point is that, within nonequivalence classes, transformation of function can involve either the same or different behavioral functions, depending on the nature of the specific relations that define the class.

Figure 20.4 The temporal-sequence relations among stimuli that became fear-inducing to a school-avoidance student.

SOME TYPES OF NONEQUIVALENCE RELATIONS

We now identify, and provide examples of, a few basic types of nonequivalence relations. All are relevant to everyday experience, but we do not mean to suggest special importance for any of the specific relations that we describe. When harnessing nonequivalence relations for applied interventions, one does not start with a specific type of relation in mind. Rather, the job is to identify specific problems that need solving, and to target the things that people do that require a functional analysis (e.g., Hayes et al., 2001; Rehfeldt & Barnes-Holmes, 2009). The stimulus relations that are implicated will vary from problem to problem, and may even include relations on which no previous research has been conducted. The onus thus falls on the applied behavior analyst to determine what relations are relevant in any specific case and to figure out how to integrate them into an intervention protocol (Rehfeldt & Barnes-Holmes, 2009). The underlying conceptual analysis can be the most laborious part of behavior programming involving derived stimulus relations, but with both equivalence and nonequivalence relations it is critical to precisely define what needs to be directly taught and what untaught relations are logically expected to emerge (e.g., Critchfield & Twyman, 2014). Becoming familiar with several different types of relations will aid in this process.

Distinction Relations

Distinction relations involve responding to stimuli in terms of their differences. In some distinction relations, there is a well-defined basis of stimulus difference. For example, on a dimension of quantity, "many" and "few" are extremes (or at least highly divergent values). Figure 20.5 provides a highly simplified example of a procedure for teaching many/few relations to children (based on Barnes-Holmes, Barnes-Holmes, Smeets, Strand, & Friman, 2004). Here the stimuli are several different types of tokens,[7] and the children learn that these tokens can be exchanged for "many" sweets versus "few" sweets. Relations are taught using a verbal procedure.[8] Thus, to teach AB relations, the teacher says, "This token [points to A] can buy many sweets. This token [A] is opposite to that token [points to B]. Which token would you use if you wanted to buy as many [or few] sweets as possible?" A correct answer is reinforced. To teach BC relations, the teacher says, "This token [points to B] is opposite to that token [points to C]. Which token would you use if you wanted to buy as many [or few] sweets as possible?" In the resulting stimulus class, the function of stimulus C should transform so that it becomes a "many" token that is "the same" as A. Children exposed to this kind of teaching in fact showed the expected derived relations. They were able to mand "more" and "less" using the coins as symbols.

The derived stimulus relations literature tends to divide distinction relations into two subtypes called *opposition* and *comparison* relations, but we are aware of no firm definitions of these subtypes. A reasonable way to think of comparison is as a dimensional distinction relation that does not involve

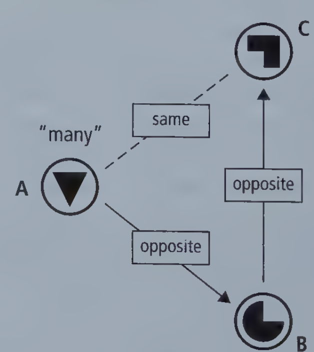

Figure 20.5 A distinction relation.

Based on "Establishing Relational Responding in Accordance with More-than and Less-than as Generalized Operant Behavior in Young Children," by Y. Barnes-Holmes and colleagues, 2004, *International Journal of Psychology and Psychological Therapy*, *4*, pp. 531–538.

"opposites"—but we know of no ironclad rule for deciding when a relation involves "opposites." Sometimes, stimuli that we call "opposite" define endpoints or extremes on some theoretically measurable dimension: "Beautiful" and "ugly" are extremes on a dimension of attractiveness, and "hyperthermia" and "hypothermia" are extremes on a dimension of body temperature. As Box 20.2 illustrates, other "opposites" reflect mutually exclusive instances for which there are no intermediate values.

Recalling that arbitrary relations are defined by the social-verbal reinforcement contingencies that create them, the simplest guide to "opposite" relations may be that often you will know one when you see it. Still, the distinction (pun intended) between opposition and comparison is not always clear cut. For instance, is a many versus few relation (Figure 20.5) really a case of opposites ("extremes on some dimension"), as Barnes-Holmes et al. (2004) described the relations in Figure 20.5? Or is this a comparison relation (after all, "more" is not "most," and "few" is not "least")? We are, frankly, unsure, so we recommend the following perspective to students who are just learning about distinction relations. If good practical reasons exist to teach a particular relation, don't worry too much about what to call it. Instead, expend your energy determining what baseline relations need to be taught to make your desired derived relations a logical outcome (see Luciano, Becerra, & Valverde, 2009).

Spatial and Temporal Relations

Spatial relationships involve the position of a stimulus in reference to the learner or some other stimulus: above versus below, left versus right, in front of versus behind, and so on. **Temporal relationships** involve the relative position of stimuli (or events) in time (e.g., before versus after, per Box 20.1 and Figure 20.4). Spatial and temporal relations are inherent in academic subjects like geography and history, respectively, and these relations are obvious components of everyday nonacademic experience. A child who does not respond appropriately to the parent instruction "Please stand *behind* Tony" or "Eat your ice cream *after* you finish your peas" may soon encounter difficulties. More serious consequences await someone who cannot respond appropriately to the statement "*Behind* you! An axe murderer!"

We are not aware of any applied studies that focus on constructing derived spatial or temporal relations in "pure" form, but several laboratory studies lay out basic procedures that might be translated for applied use (Brassil, Hyland, O'Hora, & Stewart, 2018; May, Stewart, Baez, Freegard, & Dymond, 2017). Spatial and temporal relations also are components in complex deictic relations, which involve relationships between the self and the world, and which have been the focus of considerable research, as we will describe in the "Nonequivalence Relations and Big-Picture Psychological Constructs" section.

Causal Relations

Causal relations are if-then relations. Making accurate causal attributions is an important part of negotiating the everyday world, as illustrated by the prevalence of faulty causal attributions in a variety of clinical problems (Curtis, 1989; Hayes et al., 2001; Matute & Miller, 1998; Torneke, 2010). If-then relations also

BOX 20.2

Opposite Relations in Higher-Order Mathematics

Opposite relations are important to many academic areas of study in the form of either-or categories. Chris Ninness and his colleagues used derived relational procedures to teach college students trigonometry concepts that included cosine and secant, which are reciprocals (Ninness et al., 2009). According to the rules of mathematics, an expression can be cosine or secant, but nothing is intermediate to these two cases.

Figure 20.6 summarizes some of the relations that the students mastered. An interesting feature of this work is that, consistent with what many classrooms require, the learners had to construct a response rather than simply point to a correct stimulus. For instance, shown an example of a cosine (A), they had to write it in reciprocal form (B). This opposite relation was combined with several "same" relations. Given the reciprocal (B), students had to write the equivalent formula for secant (C). Given the secant, they had to construct a graph representing the correct function (D).

Once the baseline relations had been learned, students demonstrated both "same" and "opposite" derived relations. These included the converse of the baseline relations (mutual entailment). For instance, shown the reciprocal of a cosine, they could write the cosine (opposite). Shown a secant, they could write the corresponding cosine reciprocal (same). Also demonstrated were combinatorially entailed relations between stimuli that were not directly associated during training. For example, shown a graphed function, the students could write the relevant cosine formula (opposite) or cosine reciprocal (same). These outcomes generalized to many novel instances, showing that the lesson produced a general skill rather than simply teaching the students about specific examples of cosine and secant.

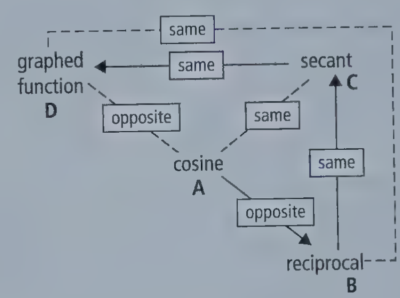

Figure 20.6 A simplified version of same and opposite relations that were established in a college-level trigonometry lesson.

Based on "Constructing and Deriving Reciprocal Trigonometric Relations: A Functional Analytic Approach," by C. Ninness and colleagues, 2009, *Journal of Applied Behavior Analysis*, *42*, pp. 191–208.

are a central feature of understanding and doing science. Just as for other kinds of nonequivalence relations, causal relations can either define the structure of a stimulus class or define the behavioral function through which stimuli in a class are transformed. We are aware of no research on either phenomenon, but in the former case it seems likely that stimuli united by overlapping causal relations (e.g., if A, then B; if B, then C) could cohere into a stimulus class. In the latter case, Box 20.3 illustrates how, for a phenomenon of potential clinical importance, the stimuli in a relational class can be transformed in terms of causal attributions.

BOX 20.3

Learned Helplessness and Transformation of Function

Many clinical conditions are characterized by negative self-evaluations (Curtis, 1989) that a behavior analyst might describe as behavior-controlling rules (Torneke, 2010; see also Chapter 18's treatment of rule-governed behavior). For instance, depressed patients may be heard to remark, "I'm no good at anything" or "Why should I try? I'll just fail" (Peterson & Bossio, 1989). According to learned helplessness theory, these self-evaluative rules are sometimes acquired under conditions of specific unpleasant experiences, during which the individual's behavior is, by definition, ineffective. Then they begin to appear in new situations, where they discourage effective action (Abramson, Seligman, & Teasdale, 1978).

To put it another way, self-evaluative rules can interfere with behavior that could generate important reinforcers (Torneke, 2010). For example, imagine that you are the victim of a mugging. You're walking down the street one night when three people jump out of nowhere, punch you several times, and rob you. The experience is very frightening and, importantly, apparently unpreventable. You were in the wrong place at the wrong time, and nothing you did could have prevented you from being overpowered. Perhaps, as a result of this experience, you say to yourself, "I'm weak and ineffective. I can't even look out for myself." This is a causal rule that can be stated in if-then form: "If placed in a situation where my well-being depends on acting effectively, I will fail." Later, you find yourself being inappropriately passive in many situations. You begin exerting little effort in your classes, which causes your grades to drop. You stop investing in your social relationships, which causes your friends to distance themselves from you. Learned helplessness theory assumes that these things happen because new situations somehow begin to evoke your "helpless" rule (Abramson et al., 1978).

How self-attributions (causal rules) are generated in the first place is a topic unto itself. For now suffice it to say that considerable research shows that humans are prolific in generating them (Barnes-Holmes, Hayes, & Dymond, 2001; Matute & Miller, 1998). Of special interest is how "helpless" self-rules, once formed, become applied to new circumstances. It seems unlikely that this is a matter of stimulus generalization (Chapters 17 and 30), as situations like "being mugged" and "taking a college class" have few physical or perceptual features in common. Thus, something else must be responsible for the spread of inappropriate passivity beyond the situation where unavoidable unpleasant events first were experienced. Cognitive psychologists have proposed that the common factor is a "helpless" mental state (Abramson et al., 1978) that moves with the individual from situation to situation. But Dack, McHugh, and Reed (2009) suggested the common factor as transformation of function involving the original unpleasant experiences and stimuli in new situations.

In the Dack et al. (2009) laboratory investigation, participants first demonstrated the formation of two equivalence classes within a match-to-sample procedure. One class incorporated the word *useless* plus two nonsense words (*lewoly* and *gedeer*), and the other incorporated *good* and two nonsense words (*matser* and *rigund*). Next, participants worked under two different reinforcement contingencies; in only one of these could reinforcement rate be increased by increasing response rate. Using a rating scale, they said that they felt more effective in gaining points on this schedule than on the other one. The two reinforcement schedules were signaled by different-colored lights. For simplicity, let's say that blue signaled the schedule that made people feel effective and yellow signaled the schedule that made them feel ineffective. Finally, in a match-to-sample test, the participants were shown a word (or nonsense word) from the equivalence classes as the sample stimulus, and the two schedule-correlated colors as comparison stimuli. They matched blue to words in the *useless* class and yellow to words in the *good* class.

What do these results show? The fact that participants matched schedule-correlated colors to *useless* and *good* stimuli reflects partly a verbal history (they already knew what those words mean) and partly new learning (they learned the "meaning" of the colors by working on the reinforcement schedules). By assigning the labels *useless* and *good* to schedule-correlated colors, participants basically generated a verbal rule to describe experience with the reinforcement schedules. Through transformation of function, we would expect the nonsense words to also be entangled in rule control. For instance, in a situation where the stimulus *lewoly* is present, the *useless* rule might be occasioned.

This experiment is not a perfect parallel to learned helplessness, but it does show how inappropriate passivity can spread to new situations through pre-existing stimulus classes. By analogy, perhaps your mugging, your school experiences, and your social relations are united in a class that might be called "places where effort and skill matter." Once a "helpless" self-rule arises in the presence of one of these situations, it should arise as well in the others.

Three Practical Considerations

Using Transformation of Function to Create New Reinforcers

Reinforcers are at the heart of just about everything in ABA, but for individuals with highly restricted interests it can be difficult to identify effective reinforcers (Tiger & Kliebert, 2011). In such cases there would be considerable value in a means of reliably creating new reinforcers, and transformation of function can be used for this purpose. Before considering how this works for nonequivalence relations, let us take up the somewhat simpler case of transformation of function in equivalence relations. If an already-effective reinforcer becomes a member of an equivalence class (e.g., using procedures described in Chapter 19), then through transformation of function, other stimuli in the class should also begin to function as reinforcers, even if they have never been directly paired with the original reinforcer. Table 20.1 shows an example (based on Hayes, Kohlenberg, & Hayes, 1991). Imagine that raisins already function as a reinforcer for some individual; audio clips of a particular song do not. The individual is taught to choose a blue triangle when shown a raisin, and also to choose the blue triangle when the audio clips are played. This should establish an equivalence class among the three stimuli, and therefore promote transformation of function. Subsequently, the audio clips (which have never been directly paired with raisins) should function as a reinforcer.[9] New consequences created in this manner have been found effective in changing behavior in standard operant situations such as reinforcement schedules and discrimination learning (Dougher, Hamilton, Fink, & Harrington, 2007; Hayes et al., 1991; Whelan, Barnes-Holmes, & Dymond, 2006).

As the preceding example shows, the behavioral function acquired by new stimuli in an equivalence class is the "same as" that served by an original stimulus. In a nonequivalence class, by contrast, transformation of function is consistent with the types of relations that define the class—sometimes with surprising results. Table 20.1 illustrates (based on Whelan and Barnes-Holmes, 2004). Imagine that pickle juice (P), an already-effective *punisher* for some individual, becomes part of a class incorporating several other stimuli and both "same as" and "opposite" relations (for explanation of how different kinds of relations can incorporate the same stimuli, see the "Theoretical Foundations" section). Two "same as" relations are taught: After smelling pickle juice, choose a blue triangle, and after hearing an audio clip of a song, choose the blue triangle. Two "opposite" relations are taught as well: Shown a picture of a cat, choose the blue triangle as its opposite, and shown a particular doll, choose the blue triangle as its opposite. Through transformation of function, the audio clip becomes a punisher (it was "same as" the blue triangle, which was "same as" the punisher). Of special importance to the present discussion, the cat and the doll became *reinforcers* (they were opposites of the blue triangle, which was "same as" the punisher). Thus, new reinforcers are created even though no other stimulus in the nonequivalence class initially functioned as a reinforcer.

Do not feel bad if you find the examples of Table 20.1 to be a little mind-bending, because standard thinking about reinforcers has not prepared you for them. The usual story told about conditioned reinforcers is that they result from the pairing of neutral stimuli with already-effective reinforcers (see Chapter 11). But the stimuli that become learned reinforcers in Table 20.1 were never directly paired with an already-effective reinforcer, suggesting that a pairing-focused account of conditioned consequences is too narrow. This is not surprising given that the pairing view arose long before the start of systematic research on derived stimulus relations (e.g., Hull, 1943; Skinner, 1938; Wyckoff, 1959). But even more recent theoretical accounts of conditioned consequences are silent on derived effects (e.g., Fantino, Preston, & Dunn, 1993; Grace & Savastano, 2000; Shahan, 2010). Thus, it is not exaggerating to say that, in this area at least, research on derived stimulus relations forces a reconsideration of the very fundamentals of behavior theory.

Returning to the mission of the present book, the effects described in Table 20.1 suggest a way to use derived stimulus

TABLE 20.1 Creating New Reinforcers Through Transformation of Function Within Equivalence and Nonequivalence Classes

Stimulus	Paired With	Type of Relation	Original Function	Transformed Function
Equivalence Class				
Raisin	Blue triangle	Same	Reinforcer	—
Audio clip	Blue triangle	Same	—	Reinforcer
Nonequivalence Class				
Pickle juice	Blue triangle	Same	Punisher	—
Audio clip	Blue triangle	Same	—	Punisher
Cat	Blue triangle	Opposite	—	Reinforcer
Doll	Blue triangle	Opposite	—	Reinforcer

Equivalence class example: Based on "The Transfer of Simple and General Consequential Functions Through Simple and Conditional Equivalence Relations," by S. C. Hayes and colleagues, 1991, *Journal of the Experimental Analysis of Behavior, 56*, 119–137. Nonequivalence class example: Based on "The Transformation of Consequential Functions in Accordance with the Relational Frames of Same and Opposite," by R. Whelan and colleagues, 2004, *Journal of the Experimental Analysis of Behavior, 82*, 177–195.

relations to create potentially endless reinforcers for any individual. Much remains to be learned, however. For example, to our knowledge the long-term durability of learned reinforcers established as in Table 20.1 has not been explored (we assume that the new reinforcers would be subject to the same motivating operations as the original reinforcer, and that derived reinforcing effects would depend on retention of the stimulus class on which transformation of function is based). This is an interesting direction for future research and application.

Incoherent Stimulus Classes

So far we have described derived stimulus relations in which the directly learned baseline relations predict the exact nature of derived relations. However, this will not be the case for every set of overlapping conditional discriminations. Consider an example involving distinction relations, summarized in Figure 20.7 (left panel), in which it is unclear on what precise basis the stimuli differ:

> If you are told that "bees are different from mammals," you cannot know what bees are like, or exactly which features differentiate them from mammals. Furthermore, the derived combinatorially entailed difference relations also are unspecified. For example, if you are told that bees are different from mammals, and that mammals are different from birds, you cannot know how bees and birds differ, or whether they are even the same (Luciano et al., 2009, p. 169).

Figure 20.7 (right panel) shows another example. A child who is just starting to learn about money is taught that *25¢* is "more than" *10¢* and also that *10¢* is "more than" *5¢*. These relations, by themselves, do not provide any basis for judging whether *10¢* or *25¢* is "more" (note that the issue is not what is true, but what can emerge from the already-mastered relations).

Also potentially undefined in classes like these is how transformation of function might proceed. For instance, in the left panel of Figure 20.7, what happens if you are attacked by a pugnacious parrot and thereafter fear birds? How (if at all) does this affect your emotional response to bees and mammals? *Something* may happen (stimulus control will always exist, and when experimental control is weak, unknown influences from the subject's learning history will predominate; Sidman, 1960), but in this case, based on the directly taught relations in the stimulus class, we cannot guess what.[10]

These examples highlight why we have stressed the importance, in derived stimulus relations interventions, of carefully mapping out the relations to be taught and the relations that logically should emerge from this teaching. A defining advantage of applied work involving derived stimulus relations is the "free learning" (in the form of untaught relations) that arises from it (e.g., Critchfield, 2018; Rehfeldt, 2011; Rehfeldt & Barnes-Holmes, 2009). From this perspective, applied relational interventions are pointless if one cannot specify the derived relations that training is expected to yield.

Tools for Planning Interventions Involving Nonequivalence Relations

Historically, an applied behavior analyst interested in teaching derived stimulus relations had to create stimuli and devise training protocols from scratch. Recently, however, efforts have been made to develop standardized tools to ease this process. We will mention two.

Training and Assessment of Relational Precursors and Abilities (TARPA) is a free software program for assessing and establishing derived stimulus relations. Several studies support its reliability and validity (Moran, Stewart, McElwee, & Ming, 2010, 2014; Moran, Walsh, Stewart, McElwee, & Ming, 2015). As of this writing, the program was available for equivalence relations only, but expansion into nonequivalence relations was under development. For information, go to http://www.vb3.co.uk/

The *PEAK* (Promoting the Emergence of Advanced Knowledge) *Relational Training System* is a commercially available assessment and treatment curriculum for adults and children with autism and related disabilities. Each volume contains 184 structured lessons and related assessment tools. One of the four volumes focuses on derived equivalence and another focuses on derived nonequivalence relations. More than 20 peer-reviewed studies provide evidence of the PEAK curriculum's reliability, validity, and effectiveness (for a review, see Dixon et al., 2017).

THEORETICAL FOUNDATIONS

The examples of the last section were intended to clarify the "what" of derived nonequivalence relations. In the present section we take up the "why" of those relations, in two ways. First, in a discussion of *contextual stimuli*, we explain how relational behavior, like all operant behavior, is situation specific. Second, we introduce a leading theory of derived relations, with emphasis on two of its most interesting propositions.

Stimulus Relations Are Defined by Contextual Control

To repeat an observation from earlier, in arbitrary stimulus relations nothing about the stimuli themselves dictates how they can be related. Rather, human social/verbal customs and reinforcement contingencies decide this. These customs and contingencies exert their influence through **contextual stimuli**, which

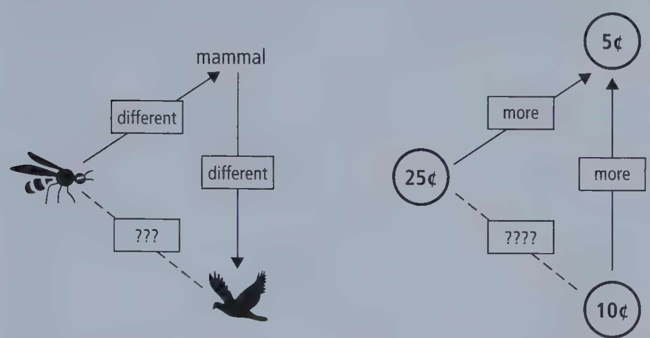

Figure 20.7 Two logically incoherent stimulus classes. Both include overlapping conditional discriminations, but the directly learned baseline relations do not support firm predictions about combinatorial entailment.

may be said to signal the specific way in which stimuli are to be related (Bush, Sidman, & Rose, 1989; Hayes, Fox et al., 2001). Figure 20.8 shows how the relations among a single set of stimuli might change depending on contextual cues. In this example (adapted from Berens & Hayes, 2007), a child must master the relations among unfamiliar coins, including a U.S. quarter (*25¢*), dime (*10¢*), and nickel (*5¢*). In the left panel, when the child is shown *25¢* and then asked, "Which is less?" a correct response is to identify *10¢*. In similar fashion the child can be taught that *5¢* is "less than" *10¢*. This should yield a derived relation in which the child, shown *10¢* and allowed to select either *5¢* or *25¢*, correctly identifies *5¢* as "less." Everything reverses, however, when the context is "more than" (center panel). And given the context of "money," the coins could be treated as equivalent (right panel; they are all types of money).[11] Thus, the same stimuli can be related in any number of ways, depending on the contextual cues.

In a sense, contextual stimuli signal what a person "needs to know" (that is, what way of relating stimuli will be reinforced) in a given situation. To get a better sense of contextual stimuli, imagine that you are completing a match-to-sample task, and the sample stimulus is *Picasso*. The comparison stimuli are *Spain*, *Michelangelo*, and *Gris*. Which one should you choose? Without knowing "the question being asked," this is an impossible decision, because each of these comparisons is an appropriate match for *Picasso* under some circumstance. *Picasso* was born in *Spain*. Like *Michelangelo*, he did some sculpting. Like Juan *Gris*, he used the painting style known as analytical cubism. Here "the question being asked" is a contextual cue that tells you on what basis you should choose a comparison stimulus. Because learned contextual cues mediate the nature of arbitrary stimulus relations in this way, contextual stimuli are an important component of applied stimulus relations interventions.

In many of the examples provided in this chapter, we mention verbal contextual stimuli (e.g., "sculpting," above) because these are easy to understand. But contextual stimuli don't have to be verbal. Imagine that you live in a lovely house, but your hobby involves survivalist adventures in which you must live off the land in the wilderness. In the context of being at home, insects fall into a class of stimuli that are to be avoided—for instance, you might call an exterminator to rid your house of termites. In the context of being alone in the forest without food, however, termites, as a source of life-saving nourishment, may fall into a class of things to be sought rather than avoided. A contextual stimulus is merely one whose presence correlates with contingencies favoring a particular way of relating.

Are Contextual Stimuli Always Essential?

The preceding sets the stage for a critical look at match-to-sample procedures for establishing derived stimulus relations like those described in Chapter 19. In much of the published research on stimulus equivalence that has been conducted to date, you will be hard pressed to find reference to contextual stimuli as we are discussing them here.[12] The example described in Figure 19.1 illustrates. During the training of each baseline relation, the sample stimulus was a spoken word, and the comparison stimuli were pictures. Thus, on one type of trial, the sample might be "car" and the comparisons might be pictures of a dog, a car, a cow, and a coffee mug. Selecting the car was reinforced. At no point during this procedure, however, was there any discrete stimulus whose presence correlated with the "same" contingency. Earlier we said that derived stimulus relations depend on contextual stimuli to signal the type of relation that should operate. Many different relation types could unite the stimuli. For instance, a coffee mug is something you might take with you in a car, "cow" starts with the same sound as "car," and a dog is something that chases a car.

How, then, did the participants know what to choose from trial to trial? Two possibilities exist. The first is that, in the relatively simple confines of the experiment (and unlike in the everyday world) only one type of relation was ever reinforced, so there was no need for contextual cues. In the experiment of Figure 19.1, once "same" responding was shaped up, it applied equally well (i.e., was reinforced) across all parts of the experiment.

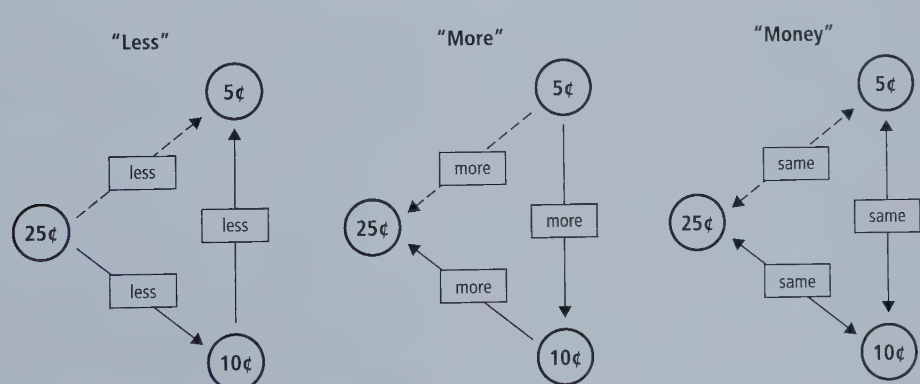

Figure 20.8 How contextual cues define stimulus relations. Left: In a "less" context, coins are related in a certain way (arrows point from the more valuable to the less valuable coin). Center: In a "more" context, those relations are reversed. Right: In the context of "money," the coins are essentially "the same."

Left and center panels are based on "Arbitrarily Applicable Comparative Relations: Experimental Evidence for a Relational Operant," by N. M. Berens and S. C. Hayes, 2007, *Journal of Applied Behavior Analysis*, *40*, 45–71.

A second possibility is that the experiment actually contained contextual stimuli, but they were implicit, meaning the overall experimental setting became a compound contextual stimulus that was correlated with reinforcement contingencies. In effect, perhaps the participant learned, "When I'm here, in this room, with this experimenter and these stimuli, I should respond with 'same.'" There is plenty of precedent for contextual cues of this type. In the classical conditioning literature, for instance, it is well established that contextual stimuli can be compounds of discrete stimuli plus aspects of the setting where conditioning took place (Bouton & Nelson, 1998).

Neither of these possibilities bodes particularly well for the generality of what is learned (Chapter 30). Someone whose relational responding is not under contextual control will be at a loss for what to do in a world where the contingencies are always changing (it will not pay, for example, to point to a picture of a car when asked, "What do you take with you in a car?"). Someone whose contextual stimuli for "same" responding are highly specific to one training situation may not make "same" responses when somewhere else.

What all this suggests to the applied behavior analyst is that efforts to create derived stimulus relations should, whenever possible, incorporate explicit, naturalistic contextual stimuli in the form of cues that are likely to be present in everyday environments. In the human world, these cues will often be verbal in nature—hence the many verbal examples employed in the present chapter. While it may be possible to build an equivalence class using a strictly nonverbal match-to-sample procedure, for verbal learners we recommend including a contextual prompt such as "pick the one that is the same," or simply, "same."

Relational Frame Theory

Now that you have a sense of what nonequivalence relations are, it will be helpful to briefly examine the leading theoretical account of them, **relational frame theory** (RFT; Hayes et al., 2001), which you encountered briefly in Chapters 18 and 19. In the present chapter we will not take up the question of whether RFT or some other theory of stimulus relations, like Sidman's (2000), is "better." However, RFT has had sufficient impact on research into derived stimulus relations that any student who wishes to become familiar with this topic needs a working understanding of the theory. To date, the vast majority of studies conducted on nonequivalence relations have been inspired by RFT, and as a result the vocabulary of nonequivalence relations used in the present chapter (e.g., *mutual entailment* and *combinatorial entailment*) comes from RFT. Additionally, although there is wide agreement that derived stimulus relations provide a basis for understanding "higher cognitive abilities" of humans (e.g., Hayes et al., 2001; Sidman, 1986, 1994), RFT researchers have been especially focused on this possibility (e.g., see the "Nonequivalence Relations and Big-Picture Psychological Constructs" section). A complete explanation of RFT is beyond the scope of the present discussion, but we will mention two key features of the theory that will help in understanding points to be made later in the chapter.

Proposition 1: The Behavior of Relating Stimuli Is Verbal Behavior

RFT assumes that derived stimulus relations are inherently verbal relations (Hayes, 1984).[13] That is, the behavior of relating stimuli *is* verbal behavior. We know of no evidence that directly confirms or refutes this assumption—it may not even be definitively testable—but it is supported by circumstantial evidence. For example, derived stimulus relations have, at best, been produced in nonhumans only rarely and as the product of considerable effort (e.g., Galizio & Bruce, 2018). This stands in stark contrast to the apparent ease with which verbally proficient humans derive stimulus relations and the broad flexibility with which they apply them (e.g., Figure 20.1). Moreover, as we will describe later in the chapter, human relational abilities appear to arise during the same period of child development in which verbal behavior grows precipitously. These observations suggest a profound linkage of derived stimulus relations and the unique verbal capabilities of humans.

Thinking of stimulus relations in terms of verbal behavior raises the interesting question of what is going on in match-to-sample protocols for establishing stimulus relations, which Chapter 19 portrayed as largely nonverbal procedures. One possibility is that in "nonverbal" circumstances learners apply covert verbal behavior to master stimulus relations (e.g., Horne & Lowe, 1996; see Chapter 19 for information about naming theory). For present purposes, however, we merely consider the possibility that, if the relating of stimuli is a verbal process, then verbal behavior can be strategically harnessed to construct stimulus relations. A number of studies show that baseline relations can be established, and derived relations promoted, by simply telling the learner about the required overlapping conditional discriminations (e.g., Berens & Hayes, 2007; Smyth, Barnes-Holmes, & Barnes-Holmes, 2008). This suggests a way, in applied work, to established stimulus relations more efficiently than through laborious match-to-sample protocols, as Box 20.4 discusses. Note that research of this type foreshadows other ways in which verbal interactions may intersect with derived stimulus relations, a topic that we will take up in this chapter's final section.

Proposition 2: Reinforced Relational Experience Yields a Generalized Relational Repertoire

Chapter 19 described equivalence classes as the result of reinforced practice with baseline relations involving specific stimuli. For example, consider the class in Figure 20.9 (top panel). According to the standard view, acquiring this class requires two kinds of baseline learning experiences: reinforced experience selecting $p \leq .05$ (rather than $p > .05$) in the presence of *low p value*, and reinforced experience selecting *statistically significant* in the presence of *low p value* (selecting the opposite answers in the presence of *high p value* also would need to be reinforced). Also according to the standard view, acquiring each new equivalence class (e.g., *overdue*, *tardy*, and *late*; top right panel of Figure 20.3) would require the analogous steps. RFT, however, proposes a developmental process that alters the nature of stimulus-class acquisition. At the core of this proposal is a disagreement with Sidman's (2000) theory

BOX 20.4

Telling Isn't Teaching—Right?

About that much-maligned mainstay of classroom teaching, the lecture, it has long been observed that "Telling isn't teaching." The corollary is that passive listening isn't learning, as Skinner (1958) suggested when advocating for teaching machines: "Unlike lectures . . . the machine induces sustained activity. The student is always alert and busy" (p. 971). In behavioral systems of instruction (e.g., Keller, 1968; Skinner, 1958), student learning is said to depend on frequent, active responding with feedback. This has been suggested specifically about equivalence-based instruction (e.g., Critchfield & Twyman, 2014).

It would therefore seem unlikely that derived stimulus relations could be established simply by telling learners about the baseline relations. But consider the case of some college students who learned about inferential statistics through an automated lesson in an online course delivery system (Critchfield, 2014). At each step of the lesson, the students were asked to read "notecards" presenting brief statements such as:

> With a low *p* value, the results are statistically significant. With a high *p* value, the results are not statistically significant.

The preceding statements incorporate two AB relations (one of which is diagrammed in Figure 20.9, top panel). After reading each statement, a student answered two to four multiple-choice questions such as

Low *p* value

A. not statistically significant
B. statistically significant

These questions were intended to serve as an attention check. Correct answers earned the feedback "Correct," and incorrect answers earned the feedback "Wrong," along with a prompt to review the relevant notecard. After this exposure to the baseline relations AB and BC, between 89% and 100% of the students answered test questions correctly about expected derived relations (BC; right panel of Figure 20.9). For instance, relevant to the relations shown in the left panel, students correctly answered this question:

$p \leq .05$

A. statistically significant
B. not statistically significant

The noteworthy feature of this lesson was its efficiency. With "telling" substituted for the elaborate sequences of match-to-sample trials that are found in many stimulus relations protocols, students completed the lesson in about 25% to 50% of the time previous students needed to master the same concepts in a match-to-sample protocol (see Fienup & Critchfield, 2010, 2011). In this particular instance, perhaps "telling" *was* teaching. Perhaps. There is uncertainty on this point because the attention-check questions did require some active responding, and even though students did not have to answer these

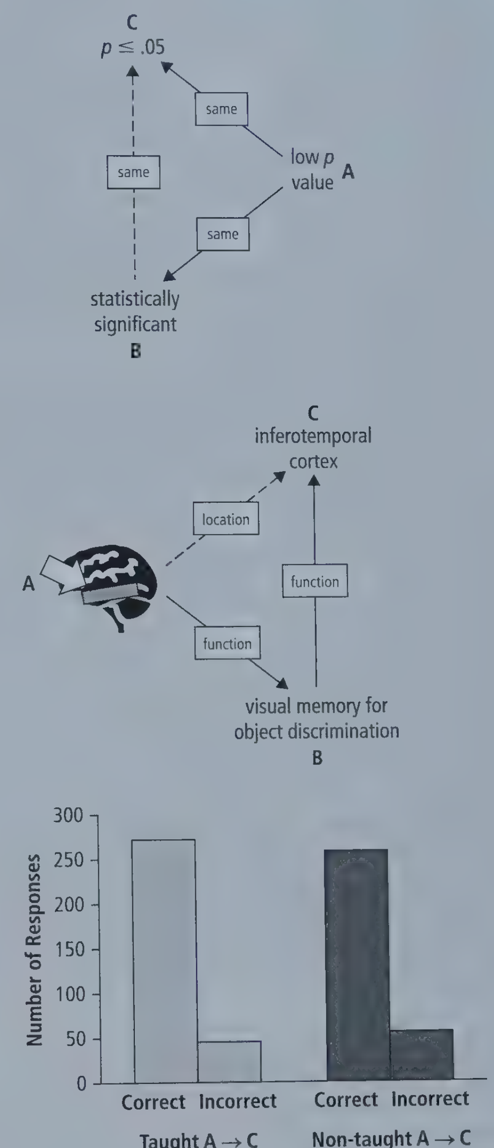

Figure 20.9 Stimulus relations established in college students by telling about baseline relations rather than reinforced match-to-sample experience. Top: Concepts related to inferential statistics. Middle: Concepts related to neuroanatomy. Bottom: Correct responses on one relation for students directly taught it versus those expected to demonstrate it emergently. For each group, separate bars show correct responding for students who did and did not first show mastery of baseline relations.

Top based on "Online Equivalence-based Instruction About Statistical Inference Using Written Explanation Instead of Match-to-Sample Training," by T. S. Critchfield, 2014, *Journal of Applied Behavior Analysis*, *47*, 606–611; middle based on "Using Stimulus Equivalence Technology to Increase Efficiency in Teaching Neuroanatomy," by C. L. Pytte and D. M. Fienup, 2012, *Journal of Undergraduate Neuroscience Education*, *10*(2), A125–A131; bottom "Using Stimulus Equivalence Technology to Increase Efficiency in Teaching Neuroanatomy," by C. L. Pytte and D. M. Fienup, 2012, *Journal of Undergraduate Neuroscience Education*, 10(2), A125–A131, Reproduced by permission from the Pytte and Fienup study.

questions correctly (there was no mastery criterion), responses did produce contingent feedback. Thus one cannot rule out that active responding and feedback, even in small doses, were necessary to the study's good outcomes.

Here a study by Pytte and Fienup (2014) is potentially informative. College students learned about neuroanatomy concepts involving brain areas, their locations in the brain, and their behavioral functions. The medium of instruction was a lecture organized to emphasize certain baseline relations. The center panel of Figure 20.9 shows one example. For seven brain regions, the AB and BC relations were explained in the lecture, but the expected derived AC relations were not. For seven other brain regions, which served as positive controls, the AC relation also was explained.

On the course exam, students averaged approximately 82% correct on questions about untaught AC relations, regardless of whether or not those relations were addressed in the lecture. Thus, "telling" about baseline relations was sufficient to promote combinatorial entailment. This is not really surprising, because past laboratory research had shown similar effects from "telling" about baseline relations (Smyth et al., 2008), and from simply "demonstrating" them by presenting pairs of stimuli without any requirement for overt responding (e.g., Leader & Barnes-Holmes, 2001a).

What is the "best" approach to establishing stimulus classes? Although "telling" and "demonstrating" alone apparently can work under at least some circumstances, perhaps even better outcomes would be obtained by requiring active responding with feedback, per the Critchfield (2014) study. On this point, however, the evidence is mixed. In comparisons of the "demonstration" procedure with match-to-sample, stimulus classes were more reliably established via the latter in one study (Clayton & Hayes, 2004) and by the former in another (Leader & Barnes-Holmes, 2001b). In at least one study with college students learning about single-subject designs, "telling" via lecture and a match-to-sample protocol promoted derived stimulus classes equally well (Lovett, Rehfeldt, Garcia, & Dunning, 2011).

To help make sense of these findings, it is worth noting an especially interesting feature of the Pytte and Fienup (2014) study that is summarized in the bottom panel of Figure 20.9. For both taught and untaught AC relations, Pytte and Fienup calculated accuracy separately for students who did, and did not, correctly answer questions about baseline relations. Regardless of whether students were told about AC, the critical issue about AC relations seemed to be that baseline AB and BC relations first were thoroughly mastered. For students who *did* acquire the baseline relations, telling was not necessary for combinatorial entailment. For students who *did not* master baseline relations, telling was insufficient for combinatorial entailment.

The Pytte and Fienup (2014) results suggest that, as with match-to-sample protocols, the critical thing about "telling" or "demonstrating" procedures may be whether they firmly establish baseline relations. Unfortunately, although "telling" and "demonstrating" have been staples of classroom instruction for centuries, the conditions under which these strategies reliably change behavior remain to be fully understood. It is therefore prudent, for the time being, to follow the lead of most work on behavioral systems of instruction (e.g., Keller, 1968; Skinner, 1958) and assume that active responding and contingent feedback, in some measure, are useful features of stimulus relations protocols. This does not, however, negate the potential of other procedures to greatly streamline the acquisition of stimulus relations by learners with adequate verbal skills.

asserting that derived relations are an automatic outcome of specific reinforcement contingencies. RFT assumes instead that, given the right learning history, the deriving of stimulus classes becomes a generalized repertoire that RFT calls *arbitrarily applicable relational responding* (Barnes-Holmes & Barnes-Holmes, 2000) that potentially applies to any number of specific stimuli.

The required learning history is reminiscent of that required to create generalized imitation (Baer, Peterson, & Sherman, 1967). For at least some learners, a teacher's command to "Do this" initially is insufficient to prompt the copying of an action like touching one's nose. Direct teaching can bring that particular action under the control of "Do this," but the prompt initially may not work with other actions (e.g., clapping). Given direct instruction of imitation of enough actions, "Do this" becomes a generalized contextual cue that prompts the copying of any action under the stimulus control of what the teacher does next. In this example you may recognize **multiple-exemplar training**, which was described in Chapter 17 as the repeated acquisition of some behavioral repertoire with variations in situations, stimuli, or response features (see also Holth, 2017). In the RFT account of generalized relational operants, each new stimulus class of a particular type (like equivalence) that reinforcement teaches is one exemplar, and given enough reinforced class formations, the deriving of stimulus classes becomes a higher-order operant that potentially applies to any number of specific stimuli. It does this through the contextual stimuli that were mentioned earlier in the chapter. In short, what multiple-exemplar training creates is generalized control by contextual stimuli.

When contextual stimuli become generalized, the relational behavior they mediate is called **arbitrarily applicable relational responding** (AARR; Hayes, Fox et al., 2001), which means forming new stimulus classes with little to no new reinforced practice. AARR involving any specific type of relation is called a **relational frame** (Hayes, Fox et al., 2001) and is thought to be acquired separately from that involving other types. A possible example of AARR is the following: When you see a supermarket sign indicating that the store's price on your favorite snack is "less than" the price at another store, you don't need any new learning experiences to know how to respond to that.

Because AARR is thought to result from accumulated multiple-exemplar experience, very young children, who lack an extensive history of reinforced relating, would be expected *not* to spontaneously demonstrate derived relations after learning baseline relations. Rather, they would need to acquire those relations by learning about baseline relations through reinforced practice. As relational experience accumulates, however, children should begin to form stimulus classes without extensive reinforced conditional discrimination training.

This perspective has two important implications. The first concerns developmental trajectories: Normatively speaking, in childhood, relational abilities should improve with age, although not necessarily at the same pace for all types of relations because each type is its own generalized class requiring its own formative experiences. In the next section, we describe evidence that supports this prediction. The second implication is that, using multiple-exemplar training, it should be possible to experimentally create a particular type of AARR. Numerous studies have shown that when enough exemplars of one type of stimulus relation are directly trained, new relations of the same type may subsequently be formed without further training (Barnes-Holmes et al., 2004; Berens & Hayes, 2007; Dunne, Foody, Barnes-Holmes, Barnes-Holmes, & Murphy, 2014; Heagle & Rehfeldt, 2006; May et al., 2017; Ninness et al., 2009).[14] Collectively, these studies remind us that a derived stimulus relations intervention can have two goals: to establish a stimulus class involving specific stimuli, and to establish a generalized repertoire through which the learner might form similar classes with new stimuli.

A brief editorial comment is in order: You needn't be a fan of RFT to appreciate studies showing generalized repertoires of relating. One of the most difficult challenges in ABA is to create behavior change that generalizes beyond the confines of a particular intervention setting (Stokes & Baer, 1968; Chapter 30). AARR may well be this kind of effect, although much remains to be learned about it. To date, research has shown mostly that, given multiple-exemplar experience, newly acquired relational repertoires can apply to novel stimuli in the same setting where an intervention took place. It is quite another matter to suggest that relational abilities acquired in one setting extend to very different ones (e.g., clinic-established relating also appears at home or at school). We are not aware of any research conducted to date that applies this stricter test of the AARR concept.[15] Nevertheless, findings like those just described underscore that it may be possible with stimulus relations interventions not just to establish a particular stimulus class of interest but also to set generalized repertoires of relating into motion.

NONEQUIVALENCE RELATIONS AND BIG-PICTURE PSYCHOLOGICAL CONSTRUCTS

As many of the diagrams in this chapter illustrate, behavior analysts often think about behavior in terms of discrete stimuli and responses, often as these unfold moment by moment. Outside of behavior analysis, people often operate at a different level of analysis. They speak of big-picture constructs like "intelligence" and "knowledge" that refer to functioning over extended time frames. Skinner (1945) saw a means of reconciling the two levels of analysis by viewing psychological constructs as umbrella terms for potentially complex behavioral phenomena. If you want to know what "intelligence" is, Skinner suggested, look at the various behavioral circumstances under which people speak of "intelligence." In his view, psychological constructs tact *something*. That something is behavior, and it can be informative to specify what kind of behavior.

From the outset, pioneering researchers of relational learning saw their mission as providing an alternative to mainstream thinking about big-picture psychological constructs (Hayes, 1984; Hayes et al., 2001; Sidman, 1986, 1994). In the present section, we briefly explore some possible connections between derived stimulus relations and three such constructs: knowledge structures, self-concept, and intellectual development.

Categorical Knowledge: Hierarchical Relations

We opened the present chapter by referring to semantic networks as hypothesized structures that organize bits of knowledge in long-term memory. Figure 20.1 showed that many different kinds of derived stimulus relations may be implicated in the behavioral phenomena that lead observers to speak of "knowledge" in the first place. One such case involves responding to stimuli in categories, which are classes within which (a) nonidentical stimuli are treated as "same," and (b) the same stimuli all are simultaneously "different" from stimuli in other classes. As Lakoff (1987) has written:

> There is nothing more basic than categorization to our thought, perception, action, and speech. Every time we see something as a *kind* of thing . . . we are categorizing. Whenever we reason about *kinds* of things—chairs, nations, emotions, any kind of thing at all—we are employing categories. . . . An understanding of how we categorize is central to any understanding of how we think and how we function, and therefore central to an understanding of what makes us human. (pp. 5–6)

Category relationships, by their nature, involve nonequivalence, and thus hierarchical relations have much in common with distinction relations. Though related to *ale*, *beer* is not the "same as" *ale*. Rather, *beer* is a category that includes *ale* (Figure 20.1), but *ale* does not include *beer*. Conversely, *ale* is a member of the category *beer*, but *beer* is not a member of the category *ale*. Such asymmetrical stimulus relations in categorization have been described as **hierarchical relations**, which involve a stimulus "including" (serving as a category label for) other stimuli, and those stimuli being "member of" the category stimulus. Hierarchical relations imply a nesting of multiple classes of stimulus relations. Thus, *India pale ale* and *English bitter*, though "different" in some ways, are "the same" in that they are members of the stimulus class *ale*. *Ale* and *lager*, though "different," are "the same" in being types of *beer*. *Beer* and *wine*, though "different," are "the same" in being types of *alcoholic beverages*, which are "different" from *nonalcoholic beverages*, though both the *alcoholic* and *nonalcoholic* varieties are types of *beverages*—and so on.

We will not attempt to explain the procedures by which derived stimulus relations researchers have built hierarchical relations because these can be quite complex (e.g., Griffee & Dougher, 2002; Paliliunas, Belisle, Barron, & Dixon, in press). A good place for the interested reader to begin may be with general considerations that apply to establishing hierarchical relations (Luciano, et al., 2009), one of the most important of which is establishing contextual stimuli that mediate whether two stimuli are related via "member of" or "includes" relations (e.g., Slattery & Stewart, 2014). For instance, in the context of "includes," *animal* "includes" *dog* (which is a type of animal), but *dog* does not "include" *animal* (which is not a type of dog). In the context of "member of," *dog* is a "member of" *animal*, but not vice versa. Once established, the contextual stimuli can assume generalized properties such that they guide the categorization of novel stimuli (Gil-Luciano, Ruiz, Valdivia-Salas, & Suárez-Falcón, 2017; Slattery & Stewart, 2014).

To summarize thus far, the research literature shows that derived stimulus relations protocols can be used to establish relations with hierarchical properties, but this does not necessarily show that similar processes operate when people learn to categorize in the everyday world. Real-world categorization typically exhibits three effects (Murphy, 2002) that any approach based on derived stimulus relations must reproduce to be credible. Box 20.5 introduces the phenomena and illustrates how hierarchical categories can be conceptualized in terms of derived

BOX 20.5

Three Characteristics of Hierarchical Categories

Researchers outside of behavior analysis have found that three properties reliably apply to the way that people categorize (Murphy, 2002). Two of these 'containment,' referring to what stimuli are subsumed by which categories, and the third concerns "property induction," which may be thought of as the transformation of behavioral functions.

Asymmetrical class containment refers to the fact that a higher-order class (e.g., "*animal*") contains a lower-order class (e.g., "dog") but not vice versa (i.e., "dog" does not contain "animal") (Slattery & Stewart, 2014, p. 61).

Figure 20.10 (top panel) shows that contextual stimuli controlling "includes" and "member of" relations can be thought of as dictating unidirectional stimulus control. The figure is arrayed such that in the "includes" context an item includes only items positioned to its right. In the "member of" context, an item is only a member of items positioned to its left. This applies equally to relations that are directly taught (e.g., in the figure, that *animal* "includes" *dog* and *ant*) and derived (e.g., *animal* includes *poodle*) relations.

Transitive class containment refers to classifying a stimulus (A) as a member of a higher-order class (C) on the basis that it is a member of a subclass (B) that is a member of that higher-order class. For example, if a child is taught that "poodle" (A) is a type of "dog" (B), then the child may also classify "poodle" as an "animal" (C) on the basis that "dog" (B) is a type of animal (Slattery & Stewart, 2014, p. 61).

The derived stimulus control of transitive class containment flows unidirectionally in accordance with contextual cues. Because *animal* "includes" *dog* and *dog* "includes" *poodle*, in Figure 20.10 *animal* is understood to "include" *poodle* even if this relation is not directly taught. In similar fashion, *poodle* would be understood as "member of" *animal*.

Unilateral property induction refers to the concept that properties or features of a higher-order class (e.g., "animal") will also be found in a lower-order class (e.g., "dog") but not vice versa. For example, all animals breathe and thus dogs breathe; however, while dogs have four legs, not all animals do (Slattery & Stewart, 2014, p. 61).

Figure 20.10 (bottom panel) depicts unilateral property induction as transformation of function flowing unidirectionally in accordance with the contextual cues. An individual who learns that "breathes" is a property of *animals* will understand that *dogs* breathe and *poodles* breathe. An individual who learns to identify "curly hair" as a property of *poodles* will not assume that all *dogs* or all *animals* share this property.

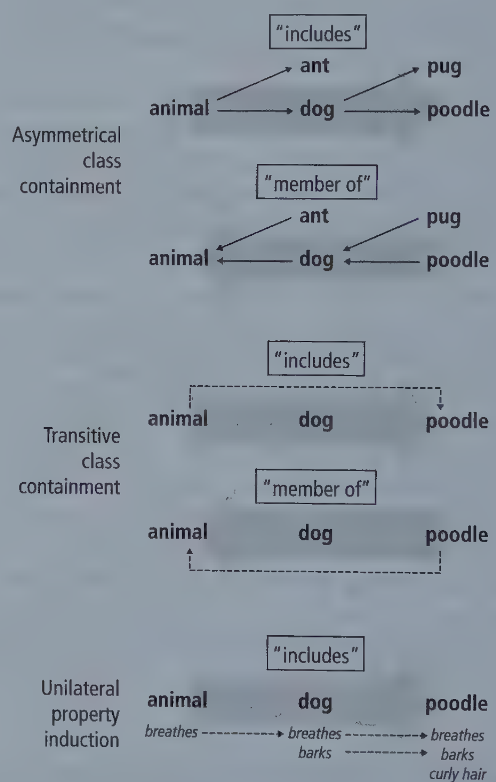

Figure 20.10 Examples of derived stimulus relations inherent in three effects commonly seen in hierarchical categorization. Note that, unlike in other diagrams in this chapter, arrows do not point from sample to comparison stimulus. Rather, arrows indicate class containment; for instance, for the contextual cue "includes," an arrow pointing from *animal* to *dog* indicates that the category *animal* includes *dog*.

stimulus relations. Recent studies have shown that these phenomena do in fact arise when hierarchical relations are created via derived stimulus relations protocols (Slattery & Stewart, 2014; Slattery, Stewart, & O'Hora, 2011).

Self-Concept: Deictic Relations

Much of this chapter has described how people relate different aspects of the world to each other. But people also focus a great deal on the relations between themselves and the world. Various psychological constructs such as identity, self-concept, and self-image at least partly address this self/world relation. As is true for *beer* (Figure 20.1), however, a "self" cannot be understood outside the context of things to which it is related. RFT provides a detailed theoretical account of various aspects of this "self" and the relations through which it arises and manifests (Barnes-Holmes, Hayes, & Dymond, 2001; Torneke, 2010). As we will note briefly in the chapter's final section, this account is useful in understanding and resolving a variety of clinical problems.

Let's start to unpack "sense of self" by considering how "self" is related to other people. Asked what her dog in the next room sees, a young child may instead describe what *she* sees. The child does not understand that one's vantage point is different from that of others. **Perspective shifting**[16] means responding as if you see the world as from another's vantage point, or perceive a situation as if were you in another's position (Batson, Early, & Salvarani, 1997). But there are other types of perspective shifting. Very young children may also confuse the perspectives of now with then (asked, "What did you do yesterday?" the child may describe what she is doing now) or the perspectives of here and there (asked, "What did you see at Grandma's?" the child may describe what she sees in her own house).

Perspective-shifting abilities correlate with general social success (e.g., McHugh, Barnes-Holmes, Barnes-Holmes, Stewart, & Dymond, 2007), and disruptions in this ability are associated with reduced "emotional intelligence" (Bar-On & Parker, 2000) and several clinical conditions (e.g., Ingram, 1990; Mullins-Nelson, Salekin, & Leistico, 2006), including autism (Baron-Cohen, Leslie, & Frith, 1985). Additionally, as this chapter's final section explains, perspective-shifting repertoires are relevant to certain problems of adjustment experienced by typically developing individuals.

In the behavior analytic view, perspective shifting involves specific kinds of stimulus relations. These are learned relations rather than the automatic product of maturation (Weil, Hayes, & Capurro, 2011), and the everyday environment does not always provide the needed learning experiences (McHugh, Barnes-Holmes, & Barnes-Holmes, 2009; Valdivia-Salas, Luciano, Gutierrez-Martinez, & Visdomine, 2009). Fortunately, research is beginning to show how to promote the acquisition of selected stimulus relations related to perspective shifting, for both typically developing children (Heagle & Rehfeldt, 2006; Montoya-Rodriguez & Cobos, 2016; Rehfeldt, Dillen, Ziomek, & Kowalchuk, 2007) and children with autism (Jackson, Mendoza, & Adams, 2014; Rehfeldt, Dillen, Ziomek, & Kowalchuk, 2007).

Most commonly, perspective shifting has been established using variants of the "Barnes-Holmes Protocol" (e.g., McHugh, Barnes-Holmes, & Barnes-Holmes, 2004; though see Guinther, 2017). The protocol incorporates a variety of self-focused distinction relations called **deictic relations**, which define the relation between the self and various aspects of the external world. Deictic relations have three dimensions. The I-YOU dimension distinguishes self from other people. The HERE-THERE dimension distinguishes between geographic locations of self versus others (HERE is always associated with I, and THERE always with YOU). The NOW-THEN dimension distinguishes between events taking place in the present versus other times.

The everyday importance of the deictic dimensions can be appreciated by considering the kinds of self-referencing verbal interactions that adults tend to have with young children. Adults may ask children questions like, "What is Mommy doing? (I/YOU), "Where are you?" (HERE/THERE), and "What did you do this morning at preschool?" (NOW/THEN). The reinforcing of correct answers forces attention to important deictic distinctions (e.g., it is difficult to correctly answer "Where are you?" without grasping that you are not your dog who is sitting in the other room). However, these are "simple" deictic relations that are not perspective shifting per se but rather prerequisites to it. Adults also ask children questions that require a reversal of perspective along one or more of the three deictic dimensions. For example, the question "What do you like to do when you are at Grandma's house?" requires a reversal of both HERE/THERE and NOW/THEN. This is an example of perspective shifting.

The Barnes-Holmes Protocol uses verbally presented scenarios about which the learner is asked to answer questions reflecting the three deictic dimensions. Table 20.2 shows examples of these scenarios. This verbal format differs from match-to-sample procedures that, in many cases, contain as little verbal content as possible.[17] The scenarios in the Barnes-Holmes Protocol represent three levels of deictic complexity (Table 20.2, leftmost column). *Simple* deictic relations involve the three core deictic dimensions mentioned earlier and, as mentioned previously, are not instances of perspective shifting. The building blocks of perspective shifting are *reversed* deictic relations (involving reversal along one of the three dimensions) and *double-reversed* relations (involving reversal on multiple dimensions).

You may be struck by how confusing some of the scenarios in Table 20.2 seem, even to an advanced learner like yourself. This illustrates that deictic relations do not necessarily "come naturally" and thus may not always be acquired under everyday circumstances (even by high-functioning adults; look ahead to Figure 20.11). It is therefore noteworthy that the Barnes-Holmes Protocol has been successfully used to teach perspective shifting to young children and persons with disabilities (e.g., Barron, Verkuylen, Belisle, Paliliunas, & Dixon, 2018; Belisle, Dixon, Stanley, Munoz, & Daar, 2016; Heagle & Rehfeldt, 2006; Jackson et al., 2014; Rehfeldt et al., 2007).

Intellectual Development

Intelligence

The construct of *intelligence* traces back to well before psychology was an independent discipline, and psychologists have sought to measure it for more than 100 years. Individual

TABLE 20.2 Example Items from the Barnes-Holmes Protocol for Teaching Perspective Shifting

LEVEL	*Example Item*[a]	I/YOU	HERE/THERE	NOW/THEN
Simple	I have a red brick and you have a green brick. Which brick do I have?	Simple		
	I am sitting here on the blue chair and you are sitting there on the black chair. Where are YOU sitting?	Simple	Simple	
	Yesterday I was watching television. Today I am reading. What am I doing NOW?	Simple		Simple
Reversed	I have a red brick and you have a green brick. If I was YOU and YOU were ME, which brick would I have?	Reversed		
	I am sitting here on the blue chair and you are sitting there on the black chair. If I was YOU and YOU were ME, where would YOU be sitting?	Reversed	Simple	
	I am sitting here on the blue chair and you are sitting there on the black chair. If HERE was THERE and THERE was HERE, where would YOU be sitting?	Simple	Reversed	
	Yesterday I was watching television. Today I am reading. If NOW was THEN and THEN was NOW, what would I be doing THEN?	Simple		Reversed
Double reversed	I am sitting here on the blue chair and you are sitting there on the black chair. If I WAS YOU and YOU were ME, and HERE was THERE and THERE was HERE, where would YOU be sitting?	Reversed	Reversed	Simple
	Yesterday you were sitting here on the blue chair and today you are sitting there on the black chair. If I was YOU and YOU were ME, and NOW was THEN and THEN was NOW, where would I be sitting?	Reversed	Simple	Reversed
	Yesterday I was sitting here on the blue chair and you were sitting there on the black chair. If HERE was THERE and THERE was HERE, and if NOW was THEN and THEN was NOW, where would I be sitting?	Simple	Reversed	Reversed

[a]Items can represent three different deictic dimensions (I/YOU, HERE/THERE, and NOW/THEN). Each dimension can be represented in non-deictic (simple) or deictic (reversed and double-reversed) form.

Based on Table 1 of "Teaching Perspective-Taking to Typically-Developing Children Through Derived Relational Responding," by A. I. Heagle and R. A. Rehfeldt, 2006, *Journal of Early and Intensive Behavioral Interventions*, *3*, 1–34.

differences in intelligence are seen as having practical importance; for instance, intelligence tests are used in schools for diagnosing learning issues and for placing children into educational tracks (Kaufman, 2018). Suffice it to say that any theoretical or empirical effort that sheds light on *intelligence* is likely to be of substantial interest.

The chapter introduction suggested that "knowledge" and "understanding" consist of derived stimulus relations (e.g., Figure 20.1). If this is true, then three things follow. First, people whose experiences create a wide variety of derived stimulus relations should be perceived as especially knowledgeable. Second, because what is already known is part of the raw material for new stimulus relations, those who "know a lot" have an advantage in future learning—they have more conceptual hooks, as it were, on which to hang new learning. Third, recall that rich histories of relational learning are the source of the generalized relational repertoires (AARR) that RFT hypothesizes. This may allow people to learn new things with unusual speed and flexibility, which is one basis on which they might be called *intelligent*. On the basis of these observations, RFT theorists have equated "general intelligence" with AARR (Barnes-Holmes, Barnes-Holmes, et al., 2001; see also Cassidy, Roche, & O'Hora, 2010), and have begun to study the connections between relational repertoires and performance on standardized measures of intelligence.

Early results are encouraging. Several investigations have found positive correlations between standardized intelligence test scores and performance on relational tasks, including those emphasizing hierarchical relations (Mulhern, Stewart, & McElwee, 2017), temporal relations (O'Hora et al., 2008), and distinction relations (O'Hora, Pelaez, & Barnes-Holmes, 2005), as well as a battery involving multiple relation types (Colbert, Dobutowitch, Roche, & Brophy, 2017). Even more exciting, several studies have shown that intensive relation-focused interventions can significantly increase children's standardized intelligence test scores (Amd & Roche, 2018; Cassidy, Roche, Colbert, Stewart, Grey, 2016; Hayes & Stewart, 2016; Parra & Ruiz, 2016). These outcomes suggest a potentially important link between the kind of behavior change that applied behavior analysts target and larger scale measures of functioning that are valued by schools and other institutions, making this an area ripe for further investigation.

Developmental Trends in Relational Behavior

On a related topic, if relational abilities are learned over time, as RFT proposes, then one would expect to see orderly age-correlated changes in these abilities. To be clear, we are not suggesting that relational abilities automatically develop as a function of age. Rather, age is a marker for multiple-exemplar relational experience that, under the right circumstances,

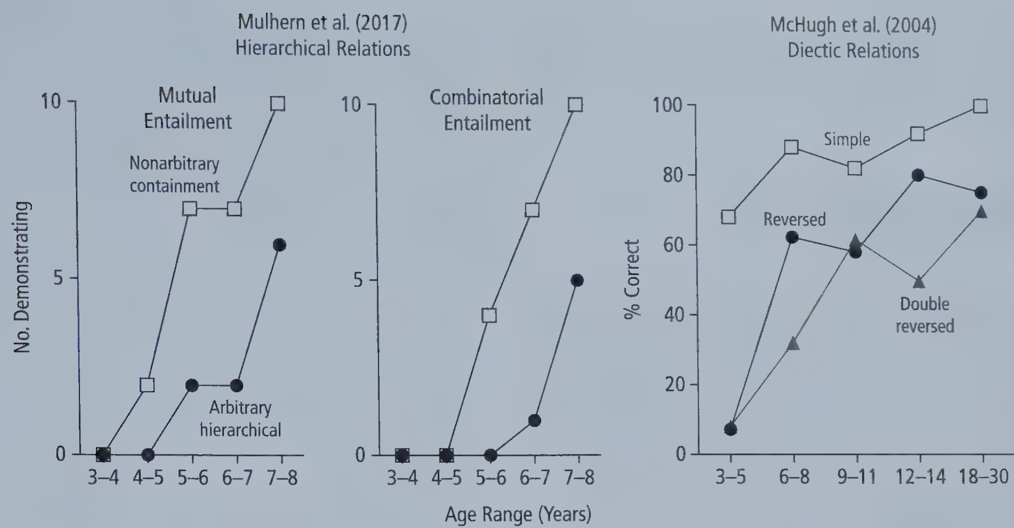

Figure 20.11 Left: Number of children (out of 10) in several age groups who demonstrated mutual and combinatorial entailment based on hierarchical stimulus relations. Each panel compares competence on a relatively simple (nonarbitrary containment) and relatively complex (arbitrary hierarchical) categorization. Right: Percentage of correct responses by children in several age groups who demonstrated self-referential relations. Results are shown separately for non-deictic (simple relations) and two kinds of deictic relations.

Left: Based on Table 5 of "Investigating Relational Framing of Categorization in Young Children," by T. Mulhern, I. Stewart, & J. McElwee, *Psychological Record*, *67*, 519–536. Right: Adapted from Figure 1 of "Perspective-taking as Relational Responding: A Developmental Profile," by L. McHugh, Y. Barnes-Holmes, & D. Barnes-Holmes, *Psychological Record*, *54*, 115–144.

accumulates over time. It is entirely possible for an individual of any age to lack the relevant experience to exhibit a particular type of generalized relating. A few investigations have directly sought evidence of the development of relational abilities. Two studies, each using a longitudinal design with a single child, found evidence of equivalence-class formation only after about 19 to 23 months of age (Lipkins, Hayes, & Hayes, 1993; Luciano et al., 2007). Such findings are interesting for two reasons. First, in these studies, equivalence-class formation was preceded by the appearance of presumably prerequisite relational abilities, such as symmetrical relations. Second, normatively speaking, it is around this same age that children first reliably exhibit verbal behavior (e.g., the naming of objects) that might be thought to draw upon equivalence relations (Luinge, Post, Wit, & Goorhuis-Brouwer, 2006).

Regarding how early in development relational abilities can arise, the longitudinal studies just described are somewhat ambiguous, because they provided relational experience along with assessing relational abilities. Other studies have used cross-sectional designs that provided only enough relational experience to assess performance on a single occasion, thereby reducing the chances that the research protocol instated any new abilities. Figure 20.11 (left panel) summarizes selected findings of a study that assessed hierarchical relations in children of different ages (Mulhern et al., 2017). The figure shows the number of children, out of 10, in each age cohort who met a mastery criterion for each of several kinds of relations. The general pattern was for derived mutual entailment and combinatorial entailment based on hierarchical classes to become more prevalent with age. Shown separately are the results for relatively difficult hierarchical relations versus nonarbitrary containment, an elementary, nonhierarchical type of categorization that is based on simple physical properties of stimuli like size and color. Developmental trajectories were steeper for nonarbitrary containment, which all children demonstrated in the age 7 to 8 cohort, than for hierarchical relations, which were not reliably present even for the older children who were tested. This is consistent with the general assumption that "difficult" levels of categorization develop relatively slowly (Bornstein & Arterberry, 2010).

Figure 20.11 (right panel) summarizes the findings of a study that assessed deictic relations in individuals aged 3 to 30 years (McHugh et al., 2004). For each relation type, the figure shows the percentage of assessment trials on which these individuals answered correctly. Simple deictic relations, which do not involve perspective shifting, were evident even in the youngest children. Reversed and double-reversed relations, which do involve perspective shifting, were absent before age 6, and not completely reliable even in the 18 to 30 age cohort. This finding is intriguing for two reasons. First, the spotty acquisition of reversed/double-reversed relations is consistent with the assumption that perspective shifting is a difficult skill—for instance, compare to the developmental pattern for hierarchical relations in the left panel. Second, the trend for reversed/double-reversed relations is broadly consistent with other research reporting that, in normally developing children, reliable evidence of self-focused constructs like "theory of mind" arises around age 5. Note, however, that there may be cultural differences in developmental trajectory, as Chinese children show "theory of mind"

earlier than U.S. children (Sabbagh, Xu, Carlson, Moses, & Lee, 2006). Assuming that "culture" implies different kinds of social learning environments, this finding is consistent with the RFT position that relational abilities are learned.

DERIVED STIMULUS RELATIONS AND GENERAL WELL-BEING

The previous section addressed some big-picture psychological constructs to which derived stimulus relations of various types may be related. Here is one more: general psychological well-being. "Well-being" can mean many things, but a critical component likely involves behaving in ways that make contact with one's most valued reinforcers. A three-term-contingency view assumes that behavior follows reinforcement, so a question of interest is when this would ever *not* happen. As we describe below, one answer intersects with what is known about derived stimulus relations, and this sets the stage for **acceptance and commitment therapy** (ACT), an evidence-based behavior therapy that counts RFT among its influences and is designed to help people better contact their reinforcers (Hayes, 2005; Hayes, Strosahl, & Wilson, 2016; see also McEnteggart, 2018).

Soon we will describe selected aspects of ACT interventions, which, unlike conventional ABA interventions, rely heavily on verbal exercises (e.g., Assaz, Roche, Kanter, & Oshiro, 2018).[18] This is different enough from the *modus operandi* of conventional ABA that we must begin by explaining ACT's conceptual undergirding so that its verbally based interventions make sense. Doing so will also clarify how ACT connects to the derived stimulus relations described here and in Chapter 19 (for more on these connections, see Assaz, et al., 2018; McEnteggart, 2018).

Because some effort will be required to digest ACT's precepts, let us try to provide some motivation for doing so: ACT works. Behavior analysts are interested in data and, as an exercise in reinforcer sampling, Figure 20.12 presents some, in the form of outcomes from an intervention for direct support staff who worked with clients with developmental disabilities (Chancey et al., in press). During baseline the staff engaged clients in positive interactions only rarely. After an intervention began, positive interactions with clients more than doubled. Note, however, that this intervention was not preceded by a functional assessment (Chapter 27) and included no prompts or consequences directly targeting interactions with clients. That is, the intervention was effective despite omitting much that is used in conventional ABA. Later we will describe the intervention, but for now we proceed to the present section's punchline: We think that applied behavior analysts should be interested in *any* intervention that works, and curious about *how* it works, even if that means stepping outside the confines of familiar practices. In reading about ACT, prepare yourself for a striking departure from the type of analysis employed in conventional ABA.

How Private Events Curtail Contact with Reinforcers

The core rationale of ACT is that private events (see Chapter 18) are at the root of a variety of human challenges (Hayes, 2005). The following is a trivial example of how private events can be problematic. You are waiting for a bus to take you to work, which is a significant source of reinforcers. A woman walks by who reminds you of an old friend you haven't seen since high school. You begin to think about experiences you and your friend shared and you try to imagine what she might be doing today. This reverie ends suddenly with the sound of your bus—which you hadn't noticed approaching or loading—pulling away. By being "in your mind" (Hayes, 2005) rather than in the situation, you have missed the bus, and with it a good part of your work day. This isolated incident illustrates how private behaviors can compete with public behaviors. Now imagine what it would be like to be constantly "in your mind." Engaging in an extensive suite of private behaviors might cause you to miss a lot of reinforcers that are contingent on your public behavior. This experience is common in a variety of clinical disorders (Chawla & Ostafin, 2007), and indeed to many people without clinical disorders who fail to get full enjoyment out of life (Hayes, 2005). Box 20.6 provides a fictional, but not unrealistic, example of the latter.

Unpleasant Private Events Monopolize Attention and Occasion Problem Public Behaviors

As Box 20.6 suggests, one way in which private events compete with "well-being behaviors"—those that contact high-priority reinforcers—is simply to crowd them out. Aversive events may evoke unpleasant emotional responses that interfere with well-being behaviors (see Friman, Hayes, & Wilson, 1998). This is similar to how, for laboratory animals, "fear" elicited by electric shocks can interrupt positively reinforced behavior (e.g., Estes & Skinner, 1941). Unpleasant emotions also can potentiate public behaviors that interfere with well-being behaviors. The woman who kicks her dog after accidentally striking her thumb with a hammer illustrates the phenomenon, as do individuals who become socially aggressive after experiencing unpleasant events (e.g., Roberton, Dafferm, & Bucks, 2012).[19] Also relevant is a host of possible avoidance behaviors. For instance, imagine that a college professor must write a lengthy book chapter on a tight time line. Through stimulus relations formed during past experiences involving missed deadlines, working on the chapter elicits considerable anxiety, which the professor escapes by taking long bicycle rides when he should be writing. In this strictly hypothetical example (having *nothing* whatsoever to do with either of the present authors), biking is negatively reinforced and occurs with increasing frequency, even though in the long run this compromises reinforcers associated with finishing the chapter.

Transformation of Function Increases Contact with Suffering

Unpleasant events like being mugged (Box 20.3) may happen only once, but through transformation of function in derived stimulus relations they may be experienced repeatedly. To illustrate, let's return to the school-anxious boy, Shawn, described in Box 20.1. The boy had an unpleasant moment with his teacher, but suffering related to that moment expanded to fill a good portion of his life away from the teacher. The "spread of suffering" (see Dymond et al., 2014) began when direct experience (the reprimand) transformed the function of one stimulus (the teacher) in an already-existing stimulus class (Figure 20.4).

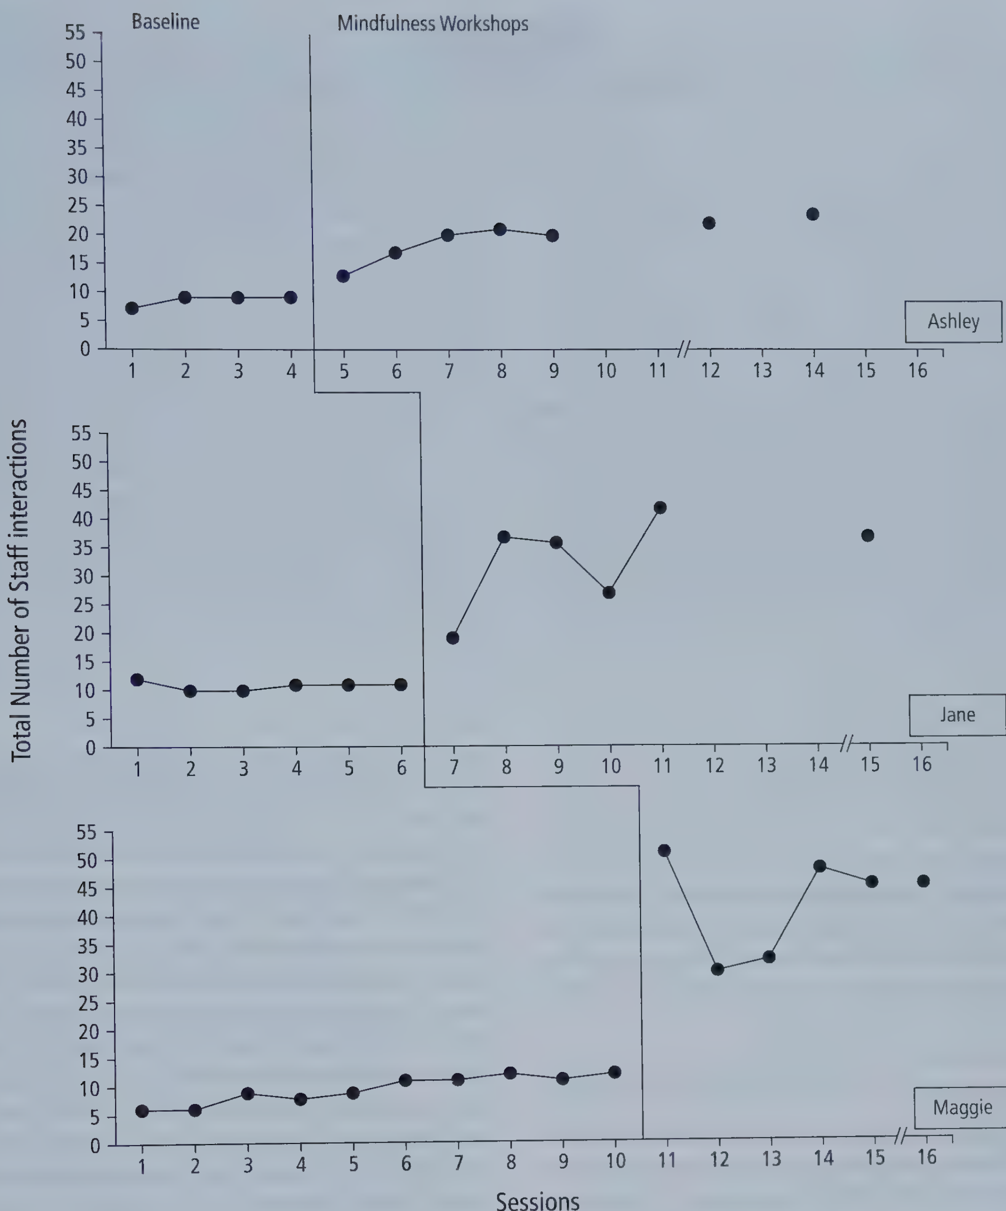

Figure 20.12 Effects of an intervention that reduced frequency of serious aggression by three adolescents.

Republished with permission of Elsevier, from The Impact of Mindfulness Skills on Interactions Between Direct Care Staff and Adults with Developmental Disabilities, C. Chancey, et al., in press, *Journal of Contextual Behavioral Science*. Permission conveyed through Copyright Clearance Center, Inc.

Other stimuli in the class acquired the same function. For Shawn, this functionally was like being yelled at by his teacher multiple times every day.

Less direct effects are possible. Let's say that on vacation you are having a lovely time visiting a Scottish castle. You adore the architecture, are impressed with the beauty of the medieval tapestries hanging on the walls, and find the history described by the tour guide to be fascinating. Thus, you're deriving an intensely pleasant stimulus class involving the castle and all of these stimuli. Then you stumble upon a coat of arms, which reminds you of your mother, who was descended from Scots and treasured the coat of arms that had been handed down through her family. Your mother passed away 2 years ago after a painful illness, and thinking of her makes you feel melancholy. This new transformation of function means that the stimulus class involving the castle will no longer involve untempered joy.

Finally, generalized relational abilities can contribute to the "spread of suffering" by transforming pleasant functions into unpleasant ones:

> Consider a six-year-old girl who drew a picture at school. Her father says, "That's nice. You did really well on that!" Given her verbal competence, the child will also be in contact with the opposite of what is said, that is, "not so nice" and "not doing very well." She may not contact this at the moment her father speaks, but she may do so at a later time, such as when she tries to draw another picture

BOX 20.6

The Private Events of Walter Mitty

> "We're going through!" The Commander's voice was like thin ice breaking. He wore his full-dress uniform, with the heavily braided white cap pulled down rakishly over one cold gray eye. "We can't make it, sir. It's spoiling for a hurricane, if you ask me." "I'm not asking you, Lieutenant Berg," said the Commander. "Throw on the power lights! Rev her up to 8,500! We're going through!" (Thurber, 1999, p. 55)

So begins the iconic James Thurber short story, "The Secret Life of Walter Mitty" (which was loosely adapted into a 2013 film starring Ben Stiller and Kristin Wiig). The story follows a middle-aged man through a series of afternoon errands in town with his wife. There is no real hurricane or Lieutenant Berg; these are part of elaborate fantasies in which Mitty engages while the day's events unfold around him. At various turns, Mitty pictures himself a brave military commander, a famous surgeon, and a convict facing a firing squad.

The story is usually said to illustrate a man's desperate efforts to escape from a boring life, but quite possibly his life is boring (devoid of external reinforcers) *because* of the fantasies. Each time Mitty lapses into a fantasy, to all the world he becomes behaviorally inert. He misses out on conversations. He fails to move his car forward when the traffic light changes. He forgets what to buy in a store. The private behaviors of his fantasies crowd out public behaviors that might contact reinforcers. As a result, other people—including his wife—think Mitty strange and either withdraw from him or browbeat him in attempt to prompt useful behavior. This magnifies Mitty's isolation.

> and it doesn't turn out the way she wanted it to. She will not need anyone else to make the judgment that this is "not so nice" or that she "did not do well." (Torneke, 2010, pp. 136–137)[20]

In the end, it doesn't matter whether unpleasant experiences are "real" or derived—in fact, there is no difference in the experience of the two (Friman et al., 1998). Because of transformation of function within stimulus classes, unpleasant private events that constrain well-being behaviors can occur any place, at any time.

Excessive Rule Following Interferes with Well-being Behaviors

Recall the learned helplessness paradigm described in Box 20.3. Unpleasant experiences, like being mugged, can lead to the creation of generalized self-rules that occasion behaviors that interfere with well-being behaviors (recall how an "I'm ineffective" rule undermined college classes and social relationships). **Rule-governed behavior**, also called *instructional control*, occurs when verbal stimuli (*rules*) occasion behavior, alter motivating operations, and/or specify the consequences of that behavior (Hayes, 1989; Skinner, 1969). Rules and instructions can come from other people, as when a parent tells a child, "To avoid being hit by a car, look both ways before crossing the street." However, people contacting environmental contingencies also generate their own rules, and these verbal stimuli can control behavior just as externally generated rules do (e.g., Rosenfarb, Newland, Brannon, & Howey, 1992). Behavior under the control of rules (both self- and other-generated) often is insensitive to change by local contingencies (Hayes, 1989; Skinner, 1969).

RFT views rule governance as operating through derived stimulus relations. Rules are thought to control behavior partly because they include stimuli (words) that participate in stimulus classes with "real" (nonverbal) stimuli that control behavior. For example, for a student whose failed geometry test evokes the rule "I am terrible at math," the words "terrible" and "math" are experienced in much the same way as the actual unpleasant experience (failing the test) to which they are related. You might recognize self-rules as similar to deictic relations, person-location-time relations in the format of I-HERE-NOW. Self-rules can pervade everyday experience and broadly disrupt well-being behaviors when they are extended along deictic dimensions. The self-rule "I am terrible at math" is based on an experience that occurred at a specific time and place, but describes (hypothesized) outcomes at all times and places. This is an extension on the HERE/THERE and NOW/THEN dimensions. The same happened with the mugging victim of Box 20.3: A factual statement (*I* was not effective *in that place at that time*) extended to other situations where it might not be accurate but still could control behavior (*I* am ineffective *at all times* and *in all places*). Other problem rules may conflate the I/YOU terms, as when a man whose father was divorced 4 times derives that "*I* can never find lasting happiness in a relationship" (it is the father, not the son, whose relationship skills are in question). For an accessible general introduction to how stimulus relations facilitate rule governance, see Torneke (2010, Chapter 6).

Self-rules become problematic when the public behaviors they control interfere with well-being behaviors. Box 20.7 describes an example. Note especially in this example how behaviors controlled by self-rules are maintained by negative reinforcement. In cases like this, unpleasant private events create the motivating operations for both public behavior and the self-rules that control it. Behavior that terminates these private events is automatically strengthened (e.g., Dymond & Roche, 2009). Thus, for the school-avoidant boy in Box 20.1, hiding in the neighborhood until after the school bus departs prevents school-related fear. For the germ-obsessed parent in Box 20.7, cleaning reduces anxiety. This is one reason why rule-governed behavior is insensitive to change: It generates its own immediate reinforcers (McEnteggart, 2018).

BOX 20.7

The Sanitation Complication[21]

Joachim was the father of two girls, ages 2 and 3. When the first daughter was born, he and his wife decided that Joachim would be a stay-at-home dad, because Joachim's wife earned more money than he did as a first-grade teacher, and in that job Joachim had been great with kids. Joachim looked forward to teaching his girls about the world through "field trips," like those he used to arrange for his students, to the park, to museums, and to the zoo. He was excited to help the girls develop strong basic academic skills before they entered school.

But Joachim struggled unexpectedly in his role as full-time parent. For reasons even he did not understand, Joachim worried constantly about protecting his daughters from germs, and he developed a suite of self-rules like "I have to keep my children safe from disease in order to be a good parent," and "I need to keep the house clean." Before long Joachim became a cleaning machine. He walked around the house with a bottle of cleaning spray, wiping down every doorknob and light switch that he passed. He scrubbed the floors and disinfected every surface of the kitchen multiple times each day.

These behaviors "worked" in the sense that they left the home spotless and reduced Joachim's anxiety about germs. But they were incompatible with many of the things Joachim had planned to do as a parent. As a result, he rarely played with the girls, and when he did, the games were interrupted by frequent spot cleaning. Joachim did not arrange any "field trips" or teach the girls to read because he was too busy disinfecting. In short, Joachim became an absentee parent in his own home. This had adverse effects on his daughters, and it deprived Joachim of many of the joys of interacting with them and of helping them develop as people. At a conscious level Joachim understood this tradeoff, but the notion of being responsible for a dangerously unsanitary environment was so aversive that he simply did not think he could help himself.

How ACT's Verbally Guided Exercises Aim to Short-circuit Harmful Private Events

In ACT, the persistent interference of private events with well-being behaviors is called *psychological inflexibility* (Hayes, 2005). We will call this **behavioral inflexibility**, and it is the opposite of *flexibility*, a capacity to be "in the moment" such that one's behavior is under the real-time stimulus control of events happening in the current situation (Hayes, 2005). ACT interventions use mainly verbally guided exercises to disrupt inflexibility and to potentiate behavior that contributes to well-being (Harris, 2008; Hayes et al., 2016). One type of ACT exercise, called *values clarification*, is designed to help people identify their most valued positive reinforcers in important life domains such as relationships, work, and leisure (Lundgren, Dahl, & Hayes, 2008). Among other functions, these exercises aid in recognizing behaviors on which the high-priority reinforcers are contingent (and with which private events may interfere).

A second kind of ACT exercise is designed to alter the aversive function of private events. Some exercises mimic exposure therapies (e.g., Wolpe, 1961) by forcing repeated contact with anxiety-provoking thoughts—for example, by repeatedly speaking aloud those thoughts until their emotional properties abate and the thought-statement is experienced merely as sound; or by imagining the anxiety-provoking thought being spoken in the ridiculous voice of a cartoon character (Harris, 2008).

A third kind of ACT exercise is designed to lessen control of private events over other behavior. An organizing concept is *mindfulness*, which has been defined as "bringing one's complete attention to the present experience on a moment-to-moment basis" (Marlatt & Kristeller, 1999, p. 68), and as observation without judgment (Baer, 2003). Some mindfulness exercises, like "Take Ten Breaths" in Box 20.8, focus on mundane external stimuli to distract attention from troublesome private events.[22] Others (like "Floating Leaves" and "Soles of the Feet" in Box 20.8) first focus attention on the mundane and then shift it to private thoughts and rules, including those that may be problematic. Here the goal is to teach how to notice private events without acting on them. For example, school-fearful Shawn (of Box 20.1) may feel anxious and afraid when he hears his school bus, but he can learn to observe these private events and still get on the bus. The cleaning-obsessed parent can notice that he repeats his rules about protecting his children without having to scrub floors every hour.

Effectiveness Evidence

By now it should be obvious that ACT interventions take a very different form than those of conventional ABA. We understand that readers who are accustomed to functionally analyzing behavior in terms of its relation to external stimuli and consequences may find ACT difficult to understand[23] and may, like some other behavior analysts, resist the suggestion that public behavior should be examined through the lens of private events (e.g., Baum, 2011; Fisher, Groff, & Roane, 2011). Yet, as empiricists, behavior analysts are committed to following the data, and there is considerable evidence supporting the effectiveness of ACT for "well-being" challenges in many domains. This includes mental health issues in schools (Burckhardt, Manicavasagar, Batterham, Hadzi-Pavlovic, & Shand, 2017; Van der Gucht et al., 2017) and in a variety of psychological conditions like anxiety, depression, addiction, chronic pain, and somatic health problems (e.g., A-Tjak et al., 2015; Hann & McCracken, 2014; Kanter, Baruch, & Gaynor, 2006). Positive effects are not, however, limited to clinical conditions. For example, ACT (or an intervention using some of its components) has reduced workplace stress (Ly, Asplund, & Andersson, 2014), increased college students' engagement with physical activity (Butryn, Forman, Hoffman, Shaw, & Juarascio, 2011), and improved athletes' performance in competition (e.g., Schwanhausser, 2009).

BOX 20.8

Three ACT Mindfulness Exercises

These exercises instruct "observation without judgment" (attending to stimuli without otherwise reacting to them). The goal of practicing them is not to prevent problematic private events but rather to disrupt their control over other behavior.

Take Ten Breaths (Harris, 2008, p. 35)

1. Throughout the day, pause for a moment and take ten slow, deep breaths. Focus on breathing out as slowly as possible, until the lungs are completely empty, and breathing in using your diaphragm.
2. Notice the sensations of your lungs emptying and your ribcage falling as you breathe out. Notice the rising and falling of your abdomen.
3. Notice what thoughts are passing through your mind. Notice what feelings are passing through your body.
4. Observe those thoughts and feelings without judging them as good or bad, and without trying to change them, avoid them, or hold on to them. Simply observe them.
5. Notice what it's like to observe those thoughts and feelings with an attitude of acceptance.

Floating Leaves on a Moving Stream (Hayes, 2005, pp. 76–77)

Imagine a beautiful, slow-moving stream. The water flows over rocks, around trees, descends downhill, and travels through a valley. Once in a while, a big leaf drops into the stream and floats away down the river. Imagine you are sitting beside that stream on a warm, sunny day, watching the leaves float by.

Now become conscious of your thoughts. Each time a thought pops into your head, imagine that it is written on one of those leaves. If you think in words, put them on the leaf as words. If you think in images, put them on the leaf as an image. The goal is to stay beside the stream and allow the leaves on the stream to keep flowing by. Don't try to make the stream go faster or slower; don't try to change what shows up on the leaves in any way. If the leaves disappear, or if you mentally go somewhere else, or if you find that you are in the stream or on a leaf, just stop and notice that this happened. File that knowledge away and then once again return to the stream, watch a thought come into your mind, write it on a leaf and let the leaf float away down the stream.

Meditation on the Soles of the Feet (Singh et al., 2011, p. 1055)

This exercise was used in an intervention, to be discussed shortly, to reduce aggression by adolescent boys (results are summarized in Figure 20.12).

1. If you are standing, stand in a natural rather than an aggressive posture, with the soles of your feet flat on the floor.
2. If you are sitting, sit comfortably with the soles of your feet flat on the floor.
3. Breathe naturally, and do nothing.
4. Cast your mind back to an incident that made you very angry. Stay with the anger.
5. You are feeling angry, and angry thoughts are flowing through your mind. Let them flow naturally, without restriction. Stay with the anger. Your body may show signs of anger (e.g., rapid breathing).
6. Now, shift all your attention fully to the soles of your feet.
7. Slowly, move your toes, feel your shoes covering your feet, feel the texture of your socks, the curve of your arch, and the heels of your feet against the back of your shoes. If you do not have shoes on, feel the floor or carpet with the soles of your feet.
8. Keep breathing naturally and focus on the soles of your feet until you feel calm.
9. Practice this mindfulness exercise until you can use it wherever you are and whenever an incident occurs that may otherwise lead to you being verbally or physically aggressive.
10. Remember that once you are calm, you can walk away from the incident or situation with a smile on your face because you controlled your anger. Alternatively, if you need to, you can respond to the incident or situation with a calm and clear mind without verbal threats or physical aggression.

Interventions using ACT or some of its components have reduced the stress and depressive symptoms of parents of children with autism spectrum disorder (ASD; Cachia, Anderson, & Moore, 2016; Singh et al., 2014), as well as developmental disabilities staff (Biglan, Layton, Jones, Hankins, & Rusby, 2013; McConachie, Mckenzie, Morris, & Walley, 2014). ACT also has been used to increase positive interactions between staff and clients (Castro, Rehfeldt, & Root, 2016). Figure 20.12, which we introduced earlier with little explanation, illustrates with data from a study by Chancey et al. (in press). Staff completed mindfulness exercises, but the intervention did not focus on client interactions per se, and there was no *in situ* prompting or reinforcement of interactions with clients. Rather, improved interactions presumably were a diffuse side effect of improved staff well-being.

Because of ACT's reliance on verbal exercises, it is not yet known how broadly applicable it may be to persons with intellectual disabilities. However, a few published applications exist, all focusing on higher-functioning individuals. In one case, ACT exercises targeting anxiety, coupled with behavioral skills training, improved job-interviewing performance in two of three individuals with developmental disabilities (Brazeau et al., 2017). A randomized controlled trial found mindfulness exercises to reduce symptoms of depression and anxiety in

adults with an ASD diagnosis (Spek, Van Ham, & Nyklicek, 2013). For a further example, examine Figure 20.13, which shows the effects of mindfulness practice on aggression in three adolescents with an ASD diagnosis (Singh et al., 2011). In this case, the mindfulness exercise ("Soles of the Feet" in Box 20.8) was expressly intended to create replacement behavior for aggression. During the first week of the intervention, the boys practiced the exercise with parental assistance for 30 minutes. Afterward they practiced under parental supervision twice per day until aggression was absent for 4 consecutive weeks. Practice stopped at that point, but the boys retained a digital audio recording of the exercise instructions that could be used as desired. Serious aggression (hitting, kicking, and biting), which occurred during baseline about 2 to 3 times per week, dropped to near-zero levels following introduction of mindfulness exercises and stayed there for about 3 years.

Although few published ACT interventions have targeted persons with developmental disabilities directly, an especially interesting phenomenon is that when ACT is used to improve the well-being of parents or staff, those they care for may experience positive trickle-down effects (Cachia et al., 2016). Figure 20.14 shows an example (Singh et al., 2014). Participants were three mothers of high-functioning adolescents with an ASD diagnosis. All three had in the past worked with applied behavior analysts but had abandoned behavioral programs because of the stress of daily implementation; they had not used behavioral programs for at least 2 years prior to the study. Across 8 weeks, the mothers completed a once-weekly workshop focusing on mindfulness-based meditation. Afterward, they were instructed to continue practicing mindfulness each morning, and parent diaries showed that on most days they did. Mother stress, as measured by a self-report rating scale, decreased from baseline to the practice phase. Concomitantly, although the workshops did not focus on behavioral interventions or even on the changing of child behavior, incidents of child aggression decreased. Disruptive behavior also decreased, and child compliance with mother requests increased (not shown in Figure 20.14).

Section Conclusion: The Functional Significance of "Well-Being"

Results like those shown in Figures 20.12 through 20.14 capture the essence of what is meant by "well-being" and of why applied behavior analysts should be interested in this construct. In contrast to most ABA interventions, those grounded in ACT do not usually target discrete problem behaviors, incorporate direct prompts, or systematically manipulate externally arranged consequences. They may teach no specific replacement behaviors. Yet by addressing very general aspects of functioning, they can have a positive impact on the kinds of problems that applied behavior analysts often address. Practitioners of ACT might argue, therefore, that conventional ABA has ignored an important context for behavior problems, that taking place within the individual. Well-being, from the perspective of ACT, exists when troublesome private events do not occasion problem behaviors or constrain behavior that contacts reinforcement.

Whether that argument registers or not, ACT is worth exploring for at least two reasons. First, relevant to the mission of the present chapter, ACT extends concepts of derived stimulus relations in unexpected directions, and this necessarily challenges the interested observer to make sure those concepts are well understood. Second, ACT illustrates how the scope of practice of an applied science can be much broader than what is often seen in ABA, which has remained heavily focused on persons with disabilities. Those who think ABA should systematically address the full range of human problems and interests (e.g., Friman, 2006; see also Chapter 1) should be intrigued by ACT's primary focus on typically developing people, and its contention that verbal behavior contributes to many human problems and can therefore be used as a tool of intervention. Those who are not persuaded by ACT's theoretical framework must reckon with data showing that it works and generate a compelling alternative explanation for why. Overall, we believe that anything that forces careful thinking about how to do the most good for the most people will be good for ABA and the people it serves.

A FINAL COMMENT

You would not be alone if you found reading the present chapter to be hard work. It is difficult to learn about equivalence classes (Chapter 19), and things become more complicated once the many additional ways of relating are taken into account. A goal of this chapter has been to persuade you that the effort

required to master this difficult topic is worth it. We have mentioned a number of ways in which derived stimulus relations concepts map onto important everyday behaviors and suggested some avenues for application. Yet even though research on derived stimulus relations began almost 50 years ago, bench-to-bedside translation has been fairly slow in developing (e.g., Critchfield, 2018; Dixon, Belisle, Rehfeldt, & Root, 2018; Rehfeldt, 2011).

There are good reasons for this. To learn about derived stimulus relations, one must first master a new vocabulary, although, as you have seen, derived stimulus relations can be complex enough that mere words do not do them justice (hence a heavy reliance on diagrams). This is a problem because most people don't think naturally in terms of the alternatives, like arrow-laden schematics. Humans, after all, are storytellers by nature (e.g., Hineline, 2018), not diagrammers and logicians. Something that this chapter and Chapter 19 can suggest but not fully illuminate is that, because derived stimulus relations have many moving parts, interventions focusing on them can be effortful to devise. No matter what potential may exist to harness derived stimulus relations concepts to create valuable behavior change, this can only happen after someone has carefully determined what to teach, how to teach it, and what derived abilities are expected to result from this.

The challenge of fully harnessing the potential of derived stimulus relations interventions now falls to you, the student, and your peers. To accomplish this, you must become so fluent with derived stimulus relations concepts, and the procedures arising from them, that applications and extensions suggest themselves effortlessly. Fortunately, there is ample precedent for mastering such challenges. Those who teach behavior analysis know that many people find even its most rudimentary concepts, like positive/negative reinforcement/punishment, to be extremely difficult. But as the present book illustrates, for those who persist, new concepts eventually become intuitive and essential building blocks for very sophisticated procedures.

Many opportunities exist to develop new derived stimulus relations interventions that target specific skills. Built properly, these are not just effective but also efficient, establishing new behaviors without directly teaching them (Critchfield, 2018; Rehfeldt, 2011; Chapter 19). In this regard, you might say that derived stimulus relations interventions can help ABA become better at what it historically has done. However, in this chapter we mentioned generalized relational repertoires (AARR), and devoted substantial space to big-picture constructs like intelligence and well-being, to illustrate that the stakes are higher than this. Looking past the complexities of the underlying concepts, you should have noticed, here and in Chapter 19, that derived stimulus relations research is not limited to particular populations or behavior problems. In this regard, it addresses the long-standing aspiration for behavior analysis to be a general-purpose science relevant to all of human experience (e.g., Skinner, 1953). There is one more consideration. Mastering derived stimulus relations concepts and following your curiosity about them may lead to work that (as the example of ACT illustrates) looks very different from conventional ABA. You may be concerned, therefore, about straying too far from the rich traditions that have made ABA so successful. To a large extent, derived stimulus relations concepts expand, rather than invalidate, ABA's foundations, but, inevitably, mastering and applying those concepts requires updates in how ABA does business. Fear not; we have it on good authority that change is acceptable.

> Regard no practice as immutable. Change and be ready to change again. Accept no eternal verity. Experiment. (Skinner, 1979, p. 346)

SUMMARY

What Are Nonequivalence Relations? Why Do They Matter?

1. *Stimulus relations* are arbitrary associations between stimuli, with "association" meaning that how one stimulus is responded to is intertwined in some way with how other stimuli are responded to.
2. Stimulus equivalence is only one of a wide variety of stimulus relations. Not all stimuli are related via "same as," and nonequivalence relations are integral to many everyday experiences.

The Vocabulary of Nonequivalence Relations

3. Key ways of talking about stimulus equivalence do not work for nonequivalence relations, so a substitute vocabulary is needed.
4. What's called *symmetry* in the stimulus equivalence literature is subsumed under the term *mutual entailment*, which means the converse of any A-to-B relation. For example, if the original relation is "A is greater than B," the converse will be "B is less than A."
5. What's called *transitivity* in the stimulus equivalence literature is subsumed under the term *combinatorial entailment*, which means any derived relation in which the function of stimuli depends on the other stimuli to which they are indirectly related.
6. What's called *transfer of function* in the stimulus equivalence literature is subsumed under the term *transformation of function*. This means that the stimuli in a relational class do not all acquire the same behavioral functions; however, the functions acquired by any stimulus depend on the functions acquired by others in the class.

Some Types of Nonequivalence Relations

7. Structured protocols similar to those used in equivalence-based instruction have been successful in establishing nonequivalence repertoires of everyday importance.

8. The notion that there are many ways of relating the same stimuli implies the existence of *contextual stimuli* that signal which way of relating is appropriate to a given situation. Explicit contextual stimuli are recommended as part of applied interventions focusing on derived stimulus relations.

9. *Distinction relations* involve relative stimuli being judged as different. *In opposition relations*, stimuli are opposites. In *comparison relations*, stimuli differ along some definable dimension.

10. Stimuli can also be related in terms of spatial or temporal juxtaposition and in terms of cause-effect relations.

11. Structured tools are just beginning to become available for programming derived stimulus relations like those described here.

Theoretical Foundations

12. Most research on nonequivalence relations has been guided by *relational frame theory*, which assumes (a) that verbal processes are bound up in derived stimulus relations, and (b) that given enough reinforced experience with multiple exemplars, people develop a higher-order ability to derive relations among sets of stimuli, even in the absence of further reinforced experience.

13. The role of verbal behavior in derived stimulus relations is not fully understood, but assuming a close connection has led to interesting research. For example, as the theory would predict, providing reinforced multiple-exemplar experience has been shown to create generalizable relational abilities. This may be an example of what relational frame theory calls *arbitrarily applicable relational responding*, a generalized repertoire that allows new classes to form without new reinforced experience.

14. It has also been found that, for some learners, the baseline relations of stimulus classes can be built simply by telling learners about them. Among other things, this finding could imply that verbal experience is functionally similar to the largely nonverbal match-to-sample experience provided in many stimulus equivalence protocols.

Nonequivalence Relations and Big-Picture Psychological Constructs

15. Categorical knowledge: Establishing a type of nonequivalence relation called *hierarchical relations* produces several effects seen in cognitive psychology studies of categorization.

16. Self-concept: A type of nonequivalence relation called *deictic relations* may underlie important self-related and social repertoires, a primary example of which is perspective shifting, in which an individual experiences the world as another person would.

17. Intellectual development: Normatively speaking, various types of derived stimulus relations tend to emerge gradually during child development. Importantly, systematically training stimulus relations has been found to boost scores on standardized intelligence tests.

Derived Stimulus Relations and General Well-Being

18. "Well-being behaviors" are those on which a person's most valued reinforcers are contingent. Many challenges to general psychological well-being involve the constraining of well-being behaviors by private events that include emotional responses and self-generated rules.

19. *Acceptance and commitment therapy* is a behavior therapy based partly on relational frame theory and research on derived stimulus relations (including nonequivalence relations). It focuses on promoting general well-being. In many cases, the therapy does not target public behaviors relevant to the referring problem. Instead, to undermine the control of behavior by problematic private events, the therapy employs verbally guided exercises that are very different from most ABA interventions.

20. The therapy has been shown to lessen symptoms of certain clinical disorders and to enhance performance in nonclinical situations. Another important application has been to reduce stress and alleviate depression in parents and caregivers of persons with disabilities. In some documented cases, improving caregiver well-being has been followed by improvements in client behavior.

KEY TERMS

acceptance and commitment therapy
arbitrarily applicable relational responding
arbitrary relations
behavioral inflexibility
causal relations
contextual stimulus
combinatorial entailment
deictic relations
derived relations
distinction relations
hierarchical relations
multiple-exemplar training
mutual entailment
nonequivalence relations
perspective shifting
relational frame theory
relational frame
rule-governed behavior
spatial relations
transformation of function
temporal relations

MULTIPLE-CHOICE QUESTIONS

1. Relational responding that experience does not directly teach, but that arises as an indirect function of experience is called:
   a. Emergent functions
   b. Derived functions
   c. Generative effect
   d. All of the above
   Hint: (See "The Vocabulary of Nonequivalence Relations")
2. The act of responding as if you see the world as from another's vantage point, or perceive a situation as if you were in another's position is called:
   a. Perspective shifting
   b. Empathy
   c. Social success
   d. Positive regard
   Hint: (See "Self Concept: Diectic Relations")
3. The core rationale of acceptance and commitment therapy suggests that the root of human challenges is/are:
   a. Private events
   b. Personality
   c. Past behavior
   d. All of the above
   Hint: (See "How Private Events Curtail Contact with Reinforcers")
4. In acceptance and commitment therapy, the persistent interference of private events with well-being behaviors is called:
   a. Maladaptive behavior
   b. Psychological inflexibility
   c. Psychosocial dysfunction
   d. Negative emotionality
   Hint: (See "How ACT's verbally guided Exercises aim to short-circuit harmful private events")
5. Classifying a stimulus as a member of a higher-order class on the basis that it is a member of the subclass that is a member of that higher-order class is called:
   a. Asymmetrical class containment
   b. Unilateral property induction
   c. Transitive class containment
   d. None of the above
   Hint: (See "Three characteristics of Hierarchical Categories")
6. The repeated acquisition of some behavioral repertoire with variations in stimuli, situations, or response feature is called
   a. Stimulus generalization
   b. Response generalization
   c. Single-exemplar training
   d. Multiple-exemplar training
   Hint: (See "Relational Frame Theory")

ESSAY-TYPE QUESTIONS

1. Discuss the types of nonequivalence relations.
   Hint: (See "Some Types of Nonequivalence Relations")
2. Name any two tools used for planning interventions involving nonequivalence relations.
   Hint: (See "Three Practical Considerations")
3. Discuss ACT's verbally guided exercises that aim to disrupt harmful private events.
   Hint: (See "How ACT's Verbally Guided Exercises Aim to Short-circuit Harmful Private Events")

NOTES

1. In keeping with tradition, we'll use the term *stimulus relations* as shorthand for various "ways of relating" (Reese, 1968; see also Critchfield, Barnes-Holmes, and Dougher, 2018). But the term is a bit of a misnomer. A stimulus relation is really a behavioral relation, a pattern in how an individual responds to groups of stimuli.
2. Compared to the semantic networks that cognitive researchers have mapped out, Figure 20.1 is quite rudimentary. *Beer* is related to many "bits of the world" that are not shown here, and each "bit" can itself be related to many other things. *Cold* is opposite to *hot*. *Lager* is made using *bottom fermentation*. A *baseball stadium* may remind you of your *father*, who used to take you to games, and so on.
3. But note that stimulus relations allow you to respond to a stimulus even when it is not physically present. For instance, you do not need to have a cold malt beverage in front of you to talk about *beer*, to picture how it looks, to imagine its taste, or to recall the embarrassing things you did last night after consuming too many. These responses can, instead, be occasioned by stimuli that participate with *beer* in arbitrary stimulus relations. This point is especially important to the chapter's final section.
4. Each trial was similar in format to a multiple-choice question. For example, when shown a picture of the frontal lobe, the student's job was to select an answer (*impulsiveness*) to which it was related, and ignore answers to which it was not (*impaired vision*, *spatial perception problems*, and *hearing problems*). Chapter 19 called this *selection-based* responding, and it likely allowed the students to succeed by responding on the basis of "any relation that exists," not of equivalence specifically.
5. The third derived property of equivalence classes, reflexivity, will not be addressed here. Reflexivity implies that a stimulus in an equivalence class is recognized as itself. This is an assumption for nonequivalence classes as well.

6. The word *entailment* means simply that one thing is dependent on another, so *mutual* entailment is when one direction of a relation (A to B) depends on, or is predictable from, the other (B to A).
7. This description is our contrivance for ease of explanation. Actually, the stimuli were several colored disks of paper, arrayed on a table surface such that the leftmost or rightmost disk served as a symbol of "many" or "few." Technically, then, this procedure confounded spatial relations (described below) with opposition relations, although that does not matter for present purposes.
8. This approach appears very different from the match-to-sample protocols described in Chapter 19. We will say more about the difference in the "Theoretical Foundations" section.
9. To repeat a point from earlier in the chapter, this might be construed as higher-order pairing, in which a neutral stimulus is paired with a stimulus that has been paired with an already-effective consequence. However, because higher-order conditioning typically is weak, it is unclear whether this explanation can account for effects like those just described.
10. There is an additional problem: For reasons too complicated to deal with here, generalized relational repertoires (arbitrarily applicable relational responding) are unlikely to arise from incoherent stimulus relations, even with multiple exemplars.
11. This phenomenon, of nonidentical stimuli being "the same" by virtue of inclusion in a common category, is one basis for *hierarchical* relations that we discuss later in the chapter.
12. Except in a handful of studies in which contextual cues are the explicit topic of investigation (e.g., Bush et al., 1989).
13. Naming theory (Horne & Lowe, 1996), introduced in Chapter 19, makes a similar assumption.
14. These studies illustrate a possible reason why "telling" and "demonstrating" procedures, which require no overt practice and provide no feedback, can produce derived stimulus relations—they may tap into already-established AARR.
15. What's also unclear is just how broadly applicable these generalized repertoires are expected to be. The RFT literature is somewhat vague on this point. The crux of the matter may concern what, precisely, functions as a contextual stimulus. The RFT literature tends to refer to discrete stimuli (like those verbal labels such as "opposite"), but if contextual stimuli can be compounds of discrete stimuli plus aspects of the setting where conditioning took place, as suggested earlier, then the repertoires they control might *not* readily generalize from one setting to another.
16. The traditional term is perspective *taking*, but that term normally is used to emphasize *only* the difference in perspective between self and other. We actually shift perspectives along multiple dimensions, as elaborated in this section.
17. Although the Barnes-Holmes Protocol has been used with children as young as 3 years of age, because of its narrative format it may yield the best results with learners at a developmental age of about 5 or older (e.g., Montoya-Rodriguez, Molina, & McHugh, 2017).
18. Among several reasons for this is that RFT assumes an intractable link between derived stimulus relations and verbal behavior, in which case any problem involving derived stimulus relations is also a problem involving verbal behavior. Verbal interventions also are compatible with the brief consultations through which clinicians often serve clients.
19. ACT theorists also assume that, through transformation of function, private events can acquire aversive properties and become the motivating operation for avoidance behaviors that reduce the private aversive stimulation but interfere with well-being behaviors. A complete explanation is beyond the scope of the present chapter.
20. This example may be easiest to appreciate by recalling from Chapter 19 that the baseline relations of stimulus classes are conditional discriminations, which means learning not just what a stimulus "is" in relational context but also what it "is not." Thus, opposition relations always are inherent in the acquisition of stimulus relations, and through a generalized opposition repertoire we are always, by experiencing pleasure, put at risk of experiencing pain when contextual cues evoke "opposite."
21. We thank Ciara McEnteggart for suggesting this example.
22. This is, perhaps, functionally similar to response interruption/redirection procedures that use "distraction" to prevent imminent stereotypical and repetitive public behaviors (e.g., Ahrens, Lerman, Kodak, Worsdell, & Keegan, 2011). Other interpretations are possible.
23. The primary literature on ACT, which any interested reader will need to consult in order to become properly conversant with ACT interventions, employs its own complex vocabulary that we mostly avoided here.

CHAPTER 21

Imitation, Modeling, and Observational Learning

LEARNING OBJECTIVES

- Define and provide examples of echoics and imitation.
- Discriminate between examples and nonexamples of imitation.
- Describe the imitation process; state what a trainer should do during the training process, based on learner performance.

Consider a trio consisting of two guitarists and a singer-songwriter performing in a contemporary rock band. During their opening set, the lead guitarist improvises a short riff. His accompanying guitarist, and band's newest and youngest member, hears the riff and then immediately reproduces it note-for-note.

Backstage between sets, the singer-songwriter says to the lead guitarist, "That was an impressive riff you dropped into our first number, but the style doesn't fit our sound. Don't play that type of riff again." The accompanying guitarist overhears the singer-songwriter's comment. During the group's second set, the lead guitarist bangs out several riffs in the same style that he played in the opening number. The accompanying guitarist does not imitate these riffs.

Imitation, modeling, and observational learning are responsible for a great deal of learning, much of it occurring without the intentional intervention by others. The two guitarists anecdote illustrates all three processes. The accompanying guitarist imitated a riff modeled by the lead guitarist. To be most adaptive, observational learning requires more than attending to and duplicating the behavior of others. Observational learners who discriminate the consequences produced by another person's behavior can better determine which behaviors to imitate. After observing the singer's disapproval of the lead guitarist's improvised riff, the accompanying guitarist stopped playing similar riffs.

The first section of this chapter defines imitation and outlines an imitation training protocol for learners who do not display imitative behavior. The chapter's second and final sections describe how applied behavior analysts use modeling as a behavior change strategy and teach children how to be skilled observational learners.

IMITATION

An imitative repertoire promotes the quick acquisition of behaviors such as a young child's development of social and communication skills. Without an imitative repertoire, a person has little chance for the agile acquisition of behaviors. Imitation has received considerable experimental and theoretical attention spanning several decades (e.g., Baer & Sherman, 1964; Carr & Kologinsky, 1983; Garcia & Batista-Wallace, 1977; Garfinkle & Schwartz, 2002; Wolery & Schuster, 1997). The experimental literature shows that individuals can acquire and maintain imitative behavior in the same fashion as they acquire and maintain other operant behaviors. That is, (a) reinforcement increases the occurrence of imitation; (b) when some imitative behaviors receive reinforcement, other imitative behaviors occur without specific training and reinforcement; and (c) some children who do not imitate can be taught to do so.

Imitation Defined

A technical definition of **imitation** entails four criteria: (a) The imitative behavior is occasioned by another person's model of the behavior (or symbolic representation thereof), (b) the imitative behavior has formal similarity with the model, (c) the imitative behavior follows the modeled behavior closely in time, and (d) the model is the primary controlling variable for the imitative behavior.

Models

A **model** is an antecedent stimulus with topographical similarity to the behavior the analyst wants to be imitated. A model can be a person who actually demonstrates a behavior (our lead guitarist playing a riff), or a model can be symbolic (i.e., a picture, video) (Bandura, 1977).

Planned models are prearranged demonstrations of behavior that show the learner exactly what to do, be it acquiring new skills or refining the topography of certain elements of existing skills.

Planned models can be live performances, as when a yoga instructor demonstrates how to achieve the adho mukha svanasana pose (a stretch in which one stands on the hands and feet; Downs, Miltenberger, Biedronski, & Witherspoon, 2015). Videos of a person performing the target behavior often serve as planned models. LeBlanc and colleagues (2003), for example, used video models to teach perspective-taking skills to three children with autism. The children learned to imitate a video model touching or pointing to objects, such as a bowl or a box. Also, the children imitated vocal-verbal behaviors, such as saying "*under the bowl*, or saying "*one.*"

Unplanned models, for better or worse, occasion imitation in everyday social environments (e.g., school, work, play, community). A tourist who has never ridden the subway system in a foreign country imitates the ticket-scanning behavior of the rider ahead of her. The turnstile opens and she enters the platform. While visiting a prospective day-care center with his parents, a child sees a series of photos of children cleaning up litter from their playground. On the way out the door, the child picks up a discarded plastic bottle and places it in the recycle bin. An undesirable outcome of imitating an unplanned model might result if an international tourist imitates a local resident jaywalking across a dangerous intersection.

Formal Similarity

Formal similarity occurs when the model's and the imitator's behavior physically resemble each other and are in the same mode (i.e., they look, or sound, alike) (Michael, 2004). For example, when a student observes a teacher fingerspell the word *house* (i.e., the model), and the student then duplicates the fingerspelling correctly (i.e., the imitation), the student's fingerspelling has formal similarity with the model. When a baby sitting in a high chair taps the food tray with his hand after seeing his mother tap the tray with her hand, the baby's tap has formal similarity to the mother's tap.

Temporal Relationship

A close temporal relationship between the model's performance and the learner's behavior is an important feature of imitation. We believe most instances of "delayed imitation" are better understood by referencing other behavioral principles and processes. The longer the latency between a previously observed model and the occurrence of behavior that duplicates the model, the more likely it is that variables other than the model are controlling the response.

Let's consider two examples that at first glance would appear to be imitation. When exiting the subway station at her destination, our international tourist emits the same turnstile operating behavior she imitated from another rider's model to gain entry to the train platform at the start of her ride. When asked by his parent, "What did you learn at school today?" a student fingerspells *h-o-u-s-e* exactly as he imitated a deaf classmate's fingerspelling the word earlier in the day.

When a response with the same topography as a previous imitation occurs in the absence of the model (e.g., another rider operating the turnstile), that response is *not* imitative behavior. The relation between a discriminative stimulus (e.g., the turnstile) that signals the availability of reinforcement because of prior experience with ticket-scans that opened a turnstile—or between a motivating operation (e.g., the parent's question) that increases the current frequency of behavior that has produced relevant reinforcement—is functionally different from the relation between an antecedent model and an imitative behavior evoked by the model. Therefore, by definition, delayed behaviors replicating the topography of a prior imitative model, are not imitative.

Model as Primary Controlling Variable

Imitation is typically viewed as *doing the same*. Although the formal similarity of *doing the same* is a necessary condition for imitation, it is not sufficient. Formal similarity can exist without the model functionally controlling the similar behavior. The most important property defining imitation is the controlling relation between a model's demonstration and a learner's performance of topographically similar behavior.

Baer, Peterson, and Sherman (1967) state: "Any behavior may be considered imitative if it temporally follows behavior demonstrated by someone else, called a model, and *if its topography is functionally controlled by the topography of the model's behavior*." (p. 405, emphasis added)

A controlling relation between the model's behavior and the imitator's behavior is inferred when a model evokes a similar behavior without a prior history of reinforcement. An imitative behavior is a *new* behavior that follows a *novel* antecedent event (i.e., the model). After the model evokes an imitative behavior, that behavior typically contacts contingencies of reinforcement. These new contingencies of reinforcement then become the controlling variables for the repetitions of the behavior (i.e., $MO \rightarrow S^D \rightarrow R \rightarrow S^R$).

Holth (2003) explained how novel instances of imitation differ from discriminated operants in this way:

> Let us imagine that a dog is trained to sit whenever the owner sits down in a chair, and to turn around in a circle whenever the owner turns around. Does the dog imitate the owner's behavior? Almost certainly not. The dog could have as easily been taught to sit whenever the owner turns around in a circle and to turn around in a circle when the owner sits down. Thus, what may look like imitation may be nothing more than a series of directly taught *discriminated operants*. The source of control can be determined only by introducing novel exemplars. In the absence of a demonstration that the dog responds to novel performances by "doing the same," there is no evidence that a similarity to the owner's behavior is important in determining the form of the dog's response. Hence, there is no true demonstration that the dog imitates the behavior of the owner unless it also responds to new instances of the owner's behavior by "doing the same." (p. 157, emphasis in original)

Holth (2003) concluded by stating that imitation "can be inferred only through instances that do not have a direct reinforcement history" (p 157). This chapter's opening anecdote included an example we infer to be true imitation. The lead guitarist improvised a short riff. The accompanying guitarist, who had never heard or played the riff, immediately reproduced

it note-for-note. The example meets the conditions for imitation: A model was present, formal similarity was achieved, a brief latency occurred between the model and the imitation, and the accompanying guitarist had no reinforcement history with the novel riff.

We'll use our two guitarists one more time to illustrate an instance of replicating another person's behavior that may appear to be imitation but is not. The lead guitarist says, "I have an idea for our opening song. Let me play it for you. If you like it, I will teach it to you." The accompanying guitarist liked what he heard. The two musicians practice the riff together until the accompanying guitarist can play it as well as the lead. Later on stage, the lead guitarist plays the riff and the accompanying guitarist immediately reproduces it. This is *not* an imitative behavior; it is an example of a discriminated operant with a history of reinforcement.

Imitation Training

An imitative repertoire enables the quick acquisition of new, complex behaviors characteristic of many human endeavors. Typically developing children acquire many skills by imitating unplanned models. Most children imitate the behavior of others without undue use of prompts or contrived reinforcement arrangements by parents, teachers, or other caregivers. Melzoff and Moore (1977) reported that infants as young as 12 to 21 days old can imitate adult hand and facial models.

For reasons that are not entirely clear, some infants and children with autism and developmental disabilities do not imitate. As a result, learning that might ordinarily progress quickly requires intensive stepwise and time-consuming instruction. Children without an imitative repertoire have little chance of rapidly developing new behaviors and great difficulty advancing beyond basic skills. Baer et al. (1967) state the importance of training such children to imitate:

> The development of a class of behaviors which may fairly be called "imitation" is an interesting task, partly because of its relevance to the process of socialization in general and language development in particular, and partly because of its potential value as a training technique for children who required special methods of instruction. (p. 405)

Imitation training is a systematic, research-based set of steps for teaching a non-imitative learner to imitate models of novel behaviors. Baer and colleagues' (1967) classic study, "The Development of Imitation by Reinforcing Behavioral Similarity to a Model," provided a pioneering demonstration of how to teach an imitative repertoire. They worked with three young children with severe to profound intellectual disabilities who did not exhibit imitative behavior. The children were taught to emit simple discriminated (i.e., similar to the model) responses (e.g., raise left arm) when the experimenter presented the verbal response cue "*Do this*," and then provided the model (e.g., raise left arm). Baer and colleagues selected appropriate skills for their participants (e.g., nod yes, stand up, put on hat, open the door). The experimenter initially used physical guidance to prompt the similar response, and then gradually reduced the guidance over several trials. The word "Good" and small bits of food were used as reinforcement to shape closer and closer topographical similarity to the experimenter's modeled responses.

The criterion for the establishment of an imitative response was the subject displaying a novel response demonstrated for the first time by the experiment with no shaping or prompting procedures for that trial.

The imitation training protocol developed by Baer and colleagues taught learners who did not imitate to imitate, meaning that a novel model controlled imitative behaviors in the absence of specific training and reinforcement of those behaviors. One participant imitated a novel model only after receiving imitation training for similarity on 130 different models. Results for the second participant were similar to those of the first. After learning just eight discriminated operants of imitative topography, Subject 3 imitated the ninth response on its first presentation. This participant imitated the ninth training model, a novel model without a history of training and reinforcement.

As a result of imitation training, two participants imitated the model with 100% similarity, but only after receiving in excess of 100 reinforced training trials. The importance of delivering positive reinforcement during and after imitation training cannot be overstated.

> The initial training procedure contained occasions when the extent of the developing imitative repertoire of each subject could be seen. These were occasions when behavior was demonstrated by the experimenter to the subject for the first time. Any attempt by the subject to imitate such new behavior before direct training or shaping could be attributed to the history of reinforcement for matching other behavior of the experimenter. (Baer, Peterson, & Sherman, 1967, p. 411)

Additionally, all three children continued to imitate new responses maintained over many sessions as long as at least some imitative responses were reinforced. When reinforcement was no longer contingent upon imitative behavior, both the previously reinforced imitations and the never reinforced probe imitations decreased markedly. However, all imitative behavior recovered when, with a small amount of shaping, reinforcement was again made contingent upon imitative behavior. Figure 21.1 shows these results for Subject 3.

The results of Baer and colleagues (1967) can be summarized as follows: (a) Children who did not have an imitative repertoire learned to imitate following a protocol that included shaping, cues, physical guidance, and reinforcement; (b) when target imitative behaviors produced reinforcement, the participants imitated other novel models without reinforcement; (c) the children demonstrated a *learning set* effect (Harlow, 1959), or a so-called *learning-to-learn* phenomenon (as the participants progressed through imitation training, they required fewer training trials to acquire new imitative repertoires); and (d) the children's imitative repertoire maintained over many sessions as long as reinforcement was contingent on at least some imitative responses.

The objective of imitation training is to teach learners to do what the person providing the model does regardless of the behavior modeled. If the training is effective, the learner

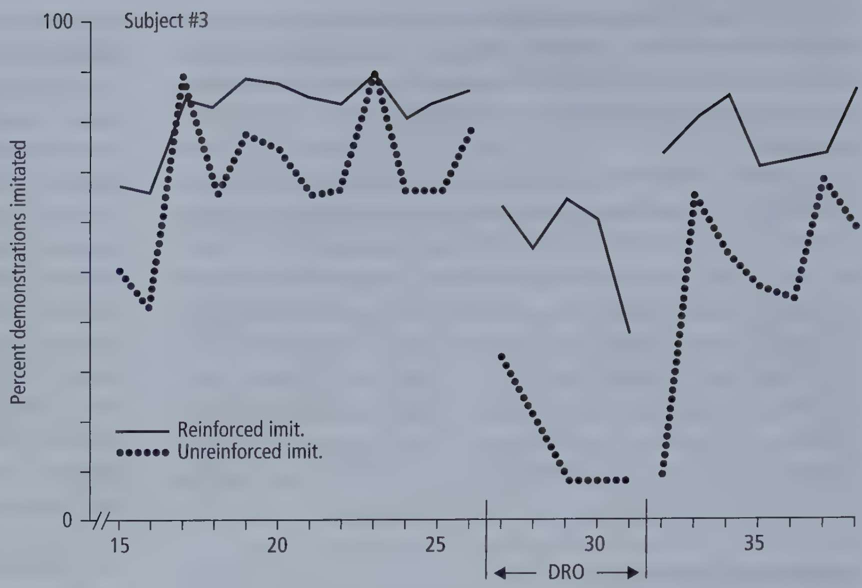

Figure 21.1 Percentage of demonstrated imitated behaviors by a child with severe/profound intellectual disabilities during reinforcement for imitation, DRO (reinforcement for any behavior other than imitation), and re-establishment of reinforcement. Solid data path shows results for eight reinforced imitations; dotted data path shows results for imitations that were never reinforced.

From "The Development of Imitation by Reinforcing Behavioral Similarity to a Model," by D. M. Baer, R. F. Peterson, and J. A. Sherman, 1967, *Journal of the Experimental Analysis of Behavior*, *21*, p. 413. Copyright 1967 by the Society for the Experimental Analysis of Behavior, Inc. Reprinted by permission.

is likely to imitate models that have not been associated with specific training, and those imitations are likely to occur in many situations and settings, frequently in the absence of planned models and reinforcement. The term **generalized imitation** is often used when a learner imitates a wide variety of unprompted, untrained, non-reinforced modeled behaviors in different settings and situations. Generalized imitation could be considered a higher order response class in which participants imitate novel models without training and that are not predictive of reinforcement.

The extent to which imitation generalizes types or classes of modeled behaviors may depend on the parameters of the response class used during training and may require programming directly. For example, Young, Krantz, McClannahan, and Poulson (1994) found that children with autism imitated novel models within the vocal, toy-play, and pantomime response types used for training, but imitation did not generalize across model types.

An Imitation Training Protocol

Building upon the experimental methods of Baer and colleagues, Striefel (1974) developed an imitation training protocol for practitioners. The components of Striefel's program are (a) assess, and teach if necessary, prerequisite skills for imitation training; (b) select models for training; (c) pretest; (d) sequence models for training; and (e) conduct imitation training.

Assess, and Teach if Necessary, Prerequisite Skills for Imitation Training

Learners cannot imitate if they do not attend to the presentation of the model. Therefore, attending to the model is a prerequisite for imitation training. Striefel (1974) defined attending as staying seated during instruction, keeping one's hands in one's lap, looking at the trainer whenever one's name is called, and looking at objects identified by the trainer. Also, practitioners often need to decrease problem behaviors that interfere with training (e.g., aggression, screaming, odd hand movements).

Suggested procedures for assessing attending skills include the following:

1. *Staying seated.* Seat the learner and record the duration of time the learner remains seated.
2. *Looking at the teacher.* Say the learner's name in a commanding voice and record whether the student makes eye contact.
3. *Keeping hands in lap.* Prompt the student to put his hands in his lap and record the duration of time the student's hands remain in that position.
4. *Looking at objects.* Place several objects on a table and say, "Look at this." Immediately following the command, move a finger from in front of the learner's eye to one of the objects and record whether the student looked at the object.

Teachers often assess attending skills for a minimum of three sessions. The teacher can begin imitation training if the assessment data show adequate attending skills. The teacher will need to teach these skills before beginning imitation training if attending skills need to be developed.

Select Models for Imitation Training

Practitioners may need to select and use about 25 behaviors as models during initial imitation training. Including gross motor (e.g., raising a hand) and fine motor movements (e.g., manual sign language) as models provides learners with opportunities to develop more refined differentiations with their imitative skills.

Practitioners usually use one model at a time during the initial training trials, rather than a sequence of movements. Practitioners may choose to use more complex models such as sequences of behavior after the learner can imitate one model per occasion successfully. Also, the initial training usually includes models of (a) the movement of body parts (e.g., touching nose, hopping on one foot, bringing hand to mouth) and (b) the manipulation of physical objects (e.g., passing a basketball, picking up a glass, zipping a coat).

Pretest

The learner's responses to the selected models should be pretested. The pretest may show that the learner will imitate some models without training. The pretesting procedures advocated by Striefel (1974) are as follows:

1. Prepare the learner's attending behaviors for the pretest (e.g., seated, hands in lap) and often assume the same ready position as the learner.
2. If you are using an object model, place one object in front of the learner and one object in front of yourself.
3. Say the learner's name to start the pretest, and when the learner makes eye contact, say, "Do this" (i.e., child's name, pause, "Do this").
4. Present the model. For example, if the selected behavior is to pick up a ball, pick up the ball yourself and hold it for a few seconds.
5. Immediately praise each response that has formal similarity to the model, and deliver the reinforcer (e.g., a hug, an edible) as quickly as possible.
6. Record the learner's response as correct or incorrect (or no response), or as an approximation of the model (e.g., touches the ball, but does not pick it up).
7. Continue pretesting with the remaining models.

Practitioners can use the pretest procedure with all motor and vocal verbal models (e.g., name, pause, "Do this," "Say ball"). Striefel recommended pretesting for several sessions until all models have been pretested at least 3 times. If the learner correctly responds during pretesting to a selected model at a set criterion level (e.g., three of three correct), then the practitioner should advance to other models. If the learner does not meet the criterion, the practitioner should select that model for imitation training.

Sequence Selected Models for Training

Practitioners use the pretest results to arrange the presentation sequence for the selected models, arranging the sequence from the easiest to the most difficult models to imitate. The first models selected for imitation training are those that the learner imitated correctly on some, but not all, of the pretest trials. The models that the learner responded to incorrectly, but that approximated the model, are selected next. Finally, the models that the learner failed to perform, or performed incorrectly, are the last to be selected for training.

Conduct Imitation Training Sessions

Striefel (1974) suggested using four conditions for imitation training sessions: preassessment, training, postassessment, and probing for imitative behaviors. The procedures used in imitation training are the same as those in the pretest, with the exception of when and how often the practitioner presents the selected models.

Preassessment. The preassessment is a short pretest given before each training session. Practitioners use the first three models currently selected for training for the preassessment. These three models are presented 3 times each in random order during the preassessment. If the learner's behavior has similarity to the model on all three presentations, that model is removed from the training. The preassessment procedure allows practitioners to evaluate the learner's current performance on the models selected for training that session, and to determine the learner's progress in learning to respond to the model.

Training. During training, practitioners use repeated presentations of one of the three models used in the preassessment. The model selected first for training is the one most often responded to during the preassessment (i.e., the behavior was similar to the model on some, but not all, of the preassessment presentations). If, however, the learner made approximations only, the behavior with the closest similarity to the model is selected first for training. Training continues until the learner responds to the model correctly on five consecutive trials.

Imitation training will likely include physical guidance to prompt the response if the learner fails to respond. For example, the practitioner may physically guide the learner's behavior through the complete response. Physical guidance allows the learner to experience the response and the reinforcer for that specific movement. After physically assisting the complete response, the practitioner will gradually withdraw the physical guidance, letting go of the student's body just before the entire movement is completed, and then continue to fade the physical guidance by withdrawing the physical support earlier on each subsequent trial. Eventually, the learner may complete the movement without assistance. When the learner responds to the model without prompting for five consecutive trials, that model is included in the postassessment.

Postassessment. During the postassessment, the practitioner presents, 3 times each, five previously learned models and five models that are still included in imitation training. The practitioner will remove a most recently learned behavior from imitation training following three consecutive postassessments in which the learner responds correctly without physical guidance to the model 14 out of the 15 opportunities. Physical guidance, however, is appropriate to use during the postassessment. If the learner does not reach this criterion (14 out of 15 postassessment opportunities), Striefel (1974) recommended continuing imitation training with that model. The postassessment procedure allows the practitioner to evaluate how well a learner performs the previously and most recently learned behaviors.

Probe for Imitation with Novel Models. Practitioners will use approximately five nontrained, novel models to probe for occurrences of imitation at the end of each imitation training session, or they will intermix the probes with the training trials. The probe procedure uses the same procedures as the preassessment activities, but without using the antecedent verbal response prompt (i.e., child's name, pause, "Do this") or other forms of response prompts (e.g., physical guidance). Probing for nontrained imitations provides data on the learner's progress in

developing an imitation repertoire—in other words, learning to do what the model does.

Guidelines for Imitation Training

Assuming that the learner has the prerequisite skills for imitation training (e.g., attending skills, existing imitative repertoire), as was the case in the Garcia et al. study, and a decision has been made as to using live versus symbolic models, the following guidelines maximize imitation training.

Keep Sessions Active and Brief

Most practitioners use short training sessions during imitation training, typically 10 to 15 minutes, but often schedule more than one session per day. Two or three 5-min sessions may be more effective than one long session. To maintain quick and active training, allow no more than a few seconds between model presentation and expected imitative response.

Reinforce Both Prompted and Imitative Responses

In the early stages of imitation training, reinforce each occurrence of prompted responses and all occurrences of imitation. If the learner's participation requires a reinforcer other than praise, use a consequence that can be presented immediately, in small amounts, and that the learner can quickly consume (e.g., cereal bits, 5 seconds of music).[1] Reinforce only matching responses or imitative behaviors that immediately follow the model (e.g., within 3 to 5 seconds). Learners who consistently emit correct matching responses, but not immediately following the model, should be reinforced for shorter response latencies (e.g., a decreasing contingency from 7 seconds to 5 seconds to 3 seconds, and so forth).

Pair Verbal Praise and Attention with Tangible Reinforcers

Often the learner's behaviors during imitation training require the use of tangible consequences such as edibles or liquids. Even so, as training progresses, it is hoped that social attention and verbal praise will maintain the matching responses or imitative behaviors. To achieve this goal, the practitioner should pair the delivery of other consequences with social and verbal praise. Social (e.g., patting the student's arm affectionately) or descriptive verbal praise should immediately follow each correct response or approximation, simultaneously with the other consequence. A learner's willingness to participate in imitation training may increase when the practitioner schedules a favorite activity to follow each session.

If Progress Stalls, Back Up and Move Ahead Slowly

There may be identifiable reasons for a worsening performance, such as reinforcer satiation or context distractions; or perhaps the practitioner presented models that were too advanced for the learner. Whether or not a clear reason exists for the worsening performance, the practitioner should immediately return to an earlier level of successful performance. Once progress resumes, training can slowly advance.

Fade Out Verbal Response Prompts and Physical Guidance

Parents and caregivers of young children almost always teach imitation skills using verbal response prompts and physical guidance. For example, the caregiver (a) tells the child to *wave bye-bye*, the caregiver models waving, and then physically guides the child's wave; (b) asks the child, "*What does the cow say?*" The caregiver presents a model, "*The cow says moo*," and then tells the child to say "*moo*"; and (c) provides praise and attention if the child says "*moo*." This natural instructional process is the same as that advocated in this chapter for teaching imitative skills to learners who do not imitate: that is, a verbal response prompt, "*Do this*"; the presentation of a model; and physical guidance when needed. However, verbal response prompts and physical guidance are not functional for producing imitation in everyday environments. Imitation training is not complete until all response prompts have been withdrawn. Children need to learn to *do what the model does* without the supports of response prompting. Therefore, to promote the effective use of imitation, fade out the response prompts used during the acquisition of trained matching responses.

Make Data-based Decisions to Terminate Imitation Training

Decisions to stop imitation training depend on the learner's behavior and program goals. For example, the practitioner could apply the criterion to terminate motor imitation training when the student imitates the first presentations of five consecutive novel models across three sessions or imitates several untrained behavior chains (e.g., washing hands, brushing teeth, fingerspelling).

MODELING

Modeling is a behavior change strategy in which learners acquire new skills by imitating demonstrations of the skills by live or symbolic models. The model shows, demonstrates, or conveys exactly the behavior the learner is expected to perform. Models can be live demonstrations or symbolic representations of the desired behavior (Bandura, 1977). A father showing his teenage son how to shave by holding and moving a razor gently across his face, and a professional golf coach demonstrating how to eliminate a hitch in a putting stroke by realigning his head and hand positions, are examples of live models. Symbolic models would be a picture icon, a photo, a video, an audio, or a mixed media presentation that illustrates or depicts the desired behavior. For example, Delli Bovi, Vladescu, DeBar, Carroll, and Sarokoff (2017) used a video model combined with voiceover instructions to teach staff how to conduct a multistep stimulus assessment procedure.

Video Modeling

Bellini and Akullian (2007) define **video modeling** as "a technique that involves demonstration of desired behaviors through video representation of the behavior. A video modeling intervention typically involves an individual watching a video

demonstration and then imitating the behavior of the model. . . . **Video self-modeling** (VSM) is a specific application of video modeling that allows the individual to imitate targeted behaviors by observing her or himself successfully performing a behavior" (p. 264).

Numerous studies have shown the positive effects of video modeling and video self-modeling across a range of ages and skills, for children and adults with various disabilities (Bellini & Akullian, 2007; Qi, Barton, Collier, & Lin, 2017; see Table 21.1). Video modeling has also been used in training applications to teach complex, multistep procedures to staff on how to conduct assessment or intervention protocols (Deliperi, Vladescu, Reeve, Reeve, & DeBar, 2015). Finally, video or self-modeling can be fashioned using standard videotape, digitally through smart pad or tablet applications, through animations, and from various camera angles and backgrounds, including so-called *point-of-view perspectives*. The fact that video modeling (VM) or VSM can be combined with instructions, feedback, and rehearsal options makes it more practical and desirable for developing new behaviors. Regardless of medium or mode, the evidence shows that video and self-modeling approaches produce imitation outcomes and, in some cases, generalized imitation outcomes.

Aldi et al. (2016) provide an example of using modeling and imitation training. They used point-of-view video models to teach daily living skills (DLS) to two 18-year-old young men with autism spectrum disorder (ASD). The two young men received training in each of their residences on three daily living skills. Participant 1 received training on cooking, setting the table, and folding jeans. Participant 2's tasks included setting the table, cleaning the bathroom sink/counter, and cleaning the mirror.

The authors used Apple iPad iOS software to create the point-of-view video models by filming family members' arms and hands doing the assigned tasks. The filming included a verbal description of each step of the tasks. Depending on the DSL to be modeled, the length of the video training tape varied, usually less than 6 minutes. Further, the number of steps that were modeled varied from 9 to 23, depending on the task (e.g., folding jeans required 9 steps, whereas cooking required 23 steps). Intervention consisted of participants watching a video related to the skill set being modeled. Subsequent to viewing the video, the participant was asked to complete the task (e.g., fold clothes). If the participant made an error, the video segment for that task was repeated as many times as necessary to achieve mastery. In some instances, gestural prompts were provided as part of an error correction procedure. Correct responses were praised.

Figure 21.2 shows that both participants mastered their respective skill sets. During a 1-month follow-up, skills maintained well above baseline levels, but were lower than the established treatment mastery levels, suggesting that additional programming for maintenance would be necessary.

Applied behavior analysts have researched the utility of a variety of models and behaviors to ascertain the effectiveness of modeling and imitation training. Overall, these advances stem from the pioneering work of Baer et al. (1967) and Bandura (1977). Table 21.1 provides a sampling of models, participants, and participants' behaviors addressed in training across daily living, safety, and academic skills.

Guidelines for Effective Modeling

It has long been established in the experimental literature that a number of factors characterize effective models (Noell, Call, & Ardoin, 2011; Sulzer-Azaroff & Mayer, 1977). The more of these characteristics that the model shares with the imitator, the more likely the modeling–imitation relationship will be established and maintained. The following sections outline several of these factors.

Model's Similarity with Learner

The similarity between the individual providing the model and the learner can influence the likelihood that imitative behavior will occur (Bandura, 1969). Almost any variable can relate to similarity: for instance, past experience, age, sex, or physical appearance. If imitation is used to teach a teenager how to reduce drug use, a person who has successfully "gone straight" might serve as an effective model, more so than someone who has not.

Prestige

A model with prestige or social status can increase the likelihood of imitative behaviors. These individuals are often leaders. For instance, high school students may imitate the dress or hair style of their favorite rock stars. Young business executives may imitate the lifestyles of their firm's senior executives. Consumers tend to buy products that are "pitched" by movie stars, celebrities, or other high-status individuals. The influence of a prestigious model is enhanced when the model and the imitator have other similar characteristics (e.g., they share music, art, or athletic interests).

Emphasize the Critical Aspect of Behavior

Emphasizing the critical aspects of the modeled stimulus can increase the likelihood of imitation. For instance, a teacher giving instruction on sight words might hold up a card with the word *blue* written on it and tell the students that the word is *blue*. The word *blue* can be emphasized by inserting a short pause between her direction, "Say . . . blue." The word can also be emphasized by destressing the intensity of the word *say* and increasing her voice volume with the word *blue*, "Say . . . BLUE." According to Risley and Reynolds (1970), emphasized stimuli increase the probability of an imitative response and boost the likelihood of imitation as a function of the emphasized model.

Instructions

Imitation can be enhanced when instructions are combined with a model's presentation. Instructions—whether spoken or written words—set the occasion for the occurrence of a specific behavior. Instructions can serve as an orienting and prompting function that increases the likelihood of imitation. A number of researchers have combined instructions, including voiceover instructions, as part of a package program to enhance the effects of video modeling (Deliperi et al., 2015).

TABLE 21.1 A Sampling of Modeling Studies Across Social, Daily Living, Safety, Academic, and Vocational Skills

Model/Format	Behavior	Learners
	Social Skills	
Self-modeling/Video (Sherer et al., 2001)	Conversation skills	Children with autism
Typically developing peer/Point-of-view video (Nikopoulos & Keenan, 2004)	Vocal or gestural initiations	Children with autism
	Daily Living Skills	
Point-of-view video modeling (Aldi et al., 2016)	Cooking, setting the table, folding jeans, cleaning bath sink/counter and mirror	Young adults with autism
Point-of-view video modeling/ Step-by-step video prompting (Cannella-Malone et al., 2011)	Starting a load of laundry and hand-washing a plate, spoon, and cup	Students with severe intellectual disabilities
Point-of-view video modeling (Shipley-Benamou, Lutzker, & Taubman 2002)	Making orange juice, preparing a letter to be mailed, setting the table, cleaning a fish bowl, feeding pet cat	Children with autism
Point-of-view step-by-step computer-presented video prompting (Sigafoos et al., 2005)	Making microwave popcorn	Adults with developmental disabilities
Live therapist modeling (Fu et al., 2015)	Food consumption	Two boys with autism and food selectivity
	Safety Skills	
Live instructor model with practice and feedback (Christensen, Lignugaris-Kraft, & Fiechtl, 1996)	First-aid skills: treating cuts	Preschoolers with disabilities
Experimenter live (Garcia, Dukes, Brady, Scott, & Wilson, 2016)	Fire safety skills	Three 4- to 5-year-old children with autism
Live and video modeling with rehearsal, praise and corrective feedback (Gunby, Carr, & LeBlanc, 2010)	Abduction-prevention responses (e.g., saying "no" when presented with a lure by a stranger, immediately running to a safe area)	Children with autism
Adult trainer/Live (Miltenberger et al., 2005)	Gun safety skills	Typically developing children ages 4 and 5 years
	Academic Skills	
Live peer vocal model (Taylor, DeQuinzio, & Stine, 2012)	Reading sight words	Children with autism
Picture prompts (Vedora & Barry, 2016)	Receptive labeling	Teenagers with autism
Video modeling (LeBlanc et al., 2003)	Perspective-taking skills	Children with autism
Step-by-step video peer model with handheld computers (Cihak, 2009)	Geometry skills	Secondary students with learning disabilities
	Vocational Skills	
Video model of scripted and naturalistic settings (Allen, Wallace, Renes, Bowen, & Burke, 2010)	Wear "Rocky the Raccoon" WalkAround costume and greet customers at retail warehouse	Adolescents and young adults with autism
Video models of peers, coworkers, job coaches performing tasks with written or voice-over instructions iPods (Kellems & Morningstar, 2012)	Vacuuming lobby, cleaning sidewalk, taking inventory of items to restock, recycling cardboard, etc.	Young adults with autism

Context

The model's presentation is more likely to be imitated if it occurs in a real situation or in a facsimile manner to the real situation. Further, these situations should be expanded to account for variations in circumstances and to promote generalized imitation.

Rehearsal and Feedback

Providing the learner with multiple opportunities to respond, combined with feedback on key elements of the model's presentation, enhances the effectiveness of modeling (Poche, Yoder, & Miltenberger, 1988). Rehearsal provides the analyst with the chance to (1) determine if the learner has acquired the imitative

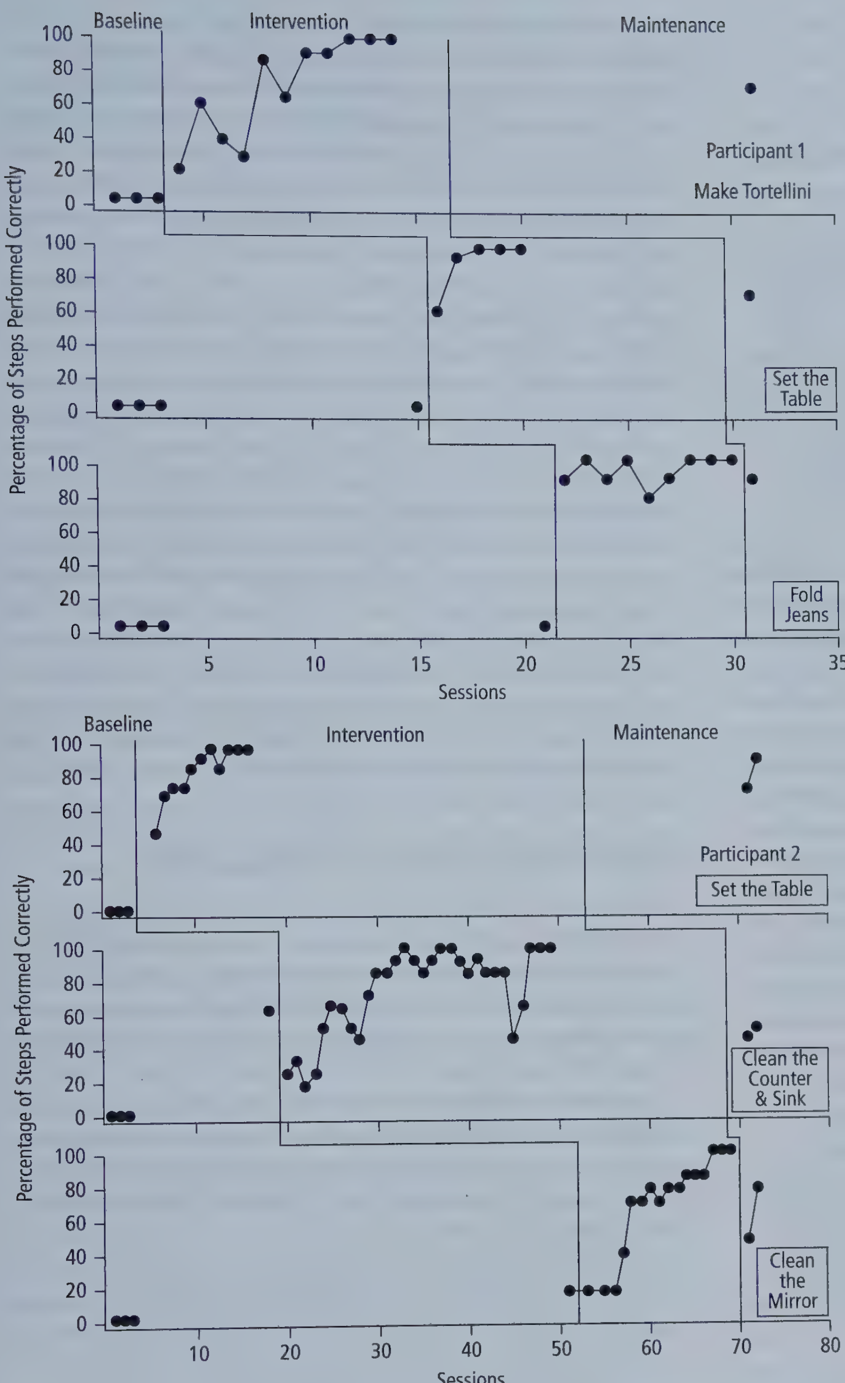

Figure 21.2 Percentage of correct daily living skills steps performed by two young men with autism.

From "Examining the Effects of Video Modeling and Prompts to Teach Activities of Daily Living Skills," by C. Aldi, A. Crigler, K. Kates-McElrath, B. Long, H. Smith, K. Rehak, and L. Wilkinson, 2016, *Behavior Analysis in Practice*, 9, p. 386. Copyright Springer International Publishing. Reprinted by permission.

skill, (2) reinforce imitative behaviors, and (3) correct any errors through feedback and redirection (Garcia, Dukes, Brady, Scott, & Wilson, 2016).

Reinforcement

The more frequently reinforcement is delivered to the imitator, the more likely imitative behavior is to increase in the future. Likewise, the more frequently the imitator observes, detects, and recognizes the model being reinforced, the more effective the model becomes (Bandura, Ross, & Ross, 1963; Noell et al., 2011).

OBSERVATIONAL LEARNING

Observational learning entails detecting another person's behavior and its consequence(s) and using that information to determine whether or not to imitate the behavior (Delgado & Greer, 2009; DeQuinzio & Taylor, 2015). Observational learning typically involves imitation but does not require it (Catania, 2013). For example, after seeing another person walking ahead of her slip on "black ice," a pedestrian may avoid that part of the sidewalk by crossing the street or stepping around it.

Does observational learning require sight? Box 21.1 explores this important question.

The objective of observational learning is that the participant "learns from indirect contact with consequences experienced by others" (Delgado & Greer, 2009, p. 408). MacDonald and Ahearn (2015) provide a classroom-related example of observational learning (OL):

> An example of OL would be when a student does not correctly point to a written word in the presence of a picture associated with the written word. The student observes another student receive instruction by a teacher followed by consequences (in the form of positive or corrective feedback). Then, because of observing this performance and the consequences that follow, the student correctly points to the word associated with the picture in the absence of direct instruction. (p. 801)

Delgado and Greer (2009) taught children with autism to discriminate the correct and incorrect sight word reading responses of confederate peers by selecting a green block if the teacher's feedback indicated the confederate peer's response was correct and selecting a red block if the teacher's feedback indicated an incorrect response. Only under conditions in which monitoring correct and incorrect feedback took place did desirable observational learning occur. The authors concluded that participants learned new sight words as a function of monitoring the correct and incorrect responses of their confederates.

It is critical that observational learners discriminate feedback received by the model. Recall that is exactly what happened in our anecdote with the guitarists. The accompanying guitarist discriminated the singer-songwriter's displeasure with the lead guitarist's improvised riff and quit playing such riffs. According to DeQuinzio and Taylor (2015), "learning this discrimination is a fundamental precondition for observational learning to occur" (p. 41).

Delgado and Greer (2009) suggest that the acquisition of observational learning skills may be a behavioral cusp:

> OL appears to be a behavioral developmental cusp. . . . a developmental cusp occurs when a child can contact contingencies that he or she could not before. . . . and it shows not only a cusp but a capability, in that the children can now learn in ways they could not before. (p. 430)

In a review of the literature, Taylor and DeQuinzio (2012) noted that children with ASD often have deficits with many of these responses. They suggested that teaching sustained attention to peer models, generalized imitation of a peer's vocal and motor responses, and discrimination of consequences could facilitate the emergence of observational learning in the natural environment. To date, however, no method exists for assessing the presence of observational learning and the skills necessary to engage in it, although studies have specifically examined teaching OL. Researchers have tried to teach OL through peer-yoked contingencies, peer monitoring, and teaching a differential observing response. Each study focused on teaching the children to attend to discriminative stimuli, to discriminate consequences related to the OL task, or both. Taylor, DeQuinzio, and Stine (2012) assessed the effects of teaching a monitoring response on the acquisition of differentially responding to words. During the training condition, participants were taught to imitate vocally the word read by the peer and to match the vocal response to the written word on the matching board. During the exposure condition, participants observed only the peer's reading response. Test conditions occurred 10 minutes after each condition to assess acquisition of the previously observed reading words. Results, though limited, suggested that all participants acquired expressive identification of words with and without monitoring.

Teaching Observational Learning Skills

As indicated earlier, many children with autism and developmental disabilities do not imitate, and observational learning is nonexistent. Children without observational learning repertoires "can learn new operants only via direct instruction, a process that is time-consuming and expensive" (Delgado & Greer, 2009, p. 431).

Three requisite skills have been identified as central to developing an observational learning repertoire: attending, imitating, and discriminating (DeQuinzio & Taylor, 2015; Greer, Dudek-Singer, & Gautreaux, 2006; Taylor & DeQuinzio, 2012; Taylor, DeQuinzio, & Stine, 2012).

Taylor and DeQuinzio (2012) and Taylor (2013) describe interventions for developing imitation and observational learning skills in persons without them. These interventions

BOX 21.1

Is Observational Learning for Sighted Persons Only?

Because observational learning connotes sight or vision, some readers may assume incorrectly that only sighted persons can profit from it. An individual who is blind uses observational learning when he attends to the auditory stimuli and consequences produced by the behavior of others and imitates those behaviors or not, accordingly. So, too, does an individual with dual sensory impairments (i.e., blind and deaf) when he senses and imitates tactile and kinesthetic stimulus products of another's behavior. Observational learning requires attention, imitation, and discrimination training regardless of sensory modes.

generally include the following three components: (a) develop attending skills; (b) teach imitation and program for generalized imitation; and (c) reinforce the discrimination of consequences—i.e., the response class "Do This, but Don't Do That"—and continued practice.

Observational learning requires several responses during and after the modeled action.

Attending

Attending means more than just being in proximity and oriented toward a stimulus. Delgado and Greer (2009) and Taylor and DeQuinzio (2012) indicated that attending at its fundamental level means that the participant, through peer- or confederate-mediated tactics, not only sustains attention toward the relevant stimulus but also makes an imitative and matching response that confirms he or she is observing that stimulus. For example, in Delgado and Greer's study the participant had to observe the confederate and then raise a differentially colored block indicating whether a correct or an incorrect response was made by the confederate. Likewise, Taylor et al. (2012) required the participant not only to repeat the stimulus word (imitation) but also to place a "chip" under that word on a separate matching board, signifying that the participant was attending to the stimulus word. In Taylor and colleagues' view, attending is a subset of a larger monitoring behavior repertoire that includes imitating a model and engaging in confirming responses to the model.

Imitating

Whether with discrete trial training (Smith, 2001), combining shaping, rehearsal, and physical guidance with imitation training (Baer et al., 1967), adding verbal description to imitation training (Jahr & Eldevik, 2002), or practicing immediate or delayed imitation with adults or peers (Taylor & DeQuinzio, 2012), teaching an imitation repertoire can be accomplished so that new, more complex repertoires of behavior develop. Taylor and DeQuinzio (2012) described how peers can be used to teach imitation:

> To teach imitation of peer responses, a teacher may initially have the child sit across from a peer at a table or in a play area. The teacher would then ask the peer to demonstrate actions (e.g., the peer is instructed to push a car back and forth) and would present an instruction to direct the child to imitate the peer (e.g., the teacher would say, "Do what John is doing"). If necessary, the teacher could guide the child to imitate the peer's action. When the child does, the teacher would provide praise and a preferred snack or toy, to reinforce the imitative response. To promote generalization, the teacher would have the peer model different actions each time, until the child can imitate novel actions without any prompting or reinforcement. (pp. 352, 353)

Discriminating

DeQuinzio and Taylor (2015) demonstrated an effective discrimination training procedure for students in whom this skill is lacking. Essentially, in their study, which included four students with autism, the researchers used a pool of unknown pictures as stimulus items. Across baseline, discrimination training, and 10-min posttest trials, they measured correct observed picture-labeling responses from reinforced and unreinforced trials between the teacher (presenting the trial) and a confederate adult model.

During a baseline condition, the teacher, who was seated across from an adult model and the participant, presented a picture with the direction, "What's this?" If the confederate adult model said the name of the picture correctly, the teacher provided praise (i.e., "That's right") and delivered a reinforcer. If the confederate, by prior arrangement, answered incorrectly, the teacher said, "I'm sorry, that's wrong," and a reinforcer on the table was removed from sight. Whether the adult model stated a correct or incorrect reply, the teacher never provided the correct picture label as part of a consequence. During the discriminating training phase, baseline conditions were repeated, except that the teacher, after providing a consequence to the model ("That's right)", turned immediately to the participant and said, "What's this?" If the participant answered correctly, praise was delivered. If the participant emitted an incorrect response, the teacher provided error correction in the form of a statement, "Say what she says when she gets it right." Correspondingly, after nonreinforced trials to the adult model, the picture was again presented to the participant immediately, with the statement "What's this?" If the participant said, "I don't know," or didn't say anything, that trial ended, and the next was initiated. Finally, generalization sessions were conducted approximately every three to five sessions, using different pictures than were used during baseline and discrimination training.

Figure 21.3 shows the results of the study. Each participant learned to discriminate reinforced responses of the confederate adult model and to say "I don't know" in the presence of nonreinforced responses to that model. The discrimination performance of the participants was maintained, albeit at a limited level, for a period of time after training using different pictures, but improved when additional training for generalization was instituted.

If any of the requisite skills for observational learning—attending, imitation, delayed imitation, and consequence discrimination—are lacking in a participant's repertoire, these skills can be taught separately and then combined to improve or enhance observational learning.

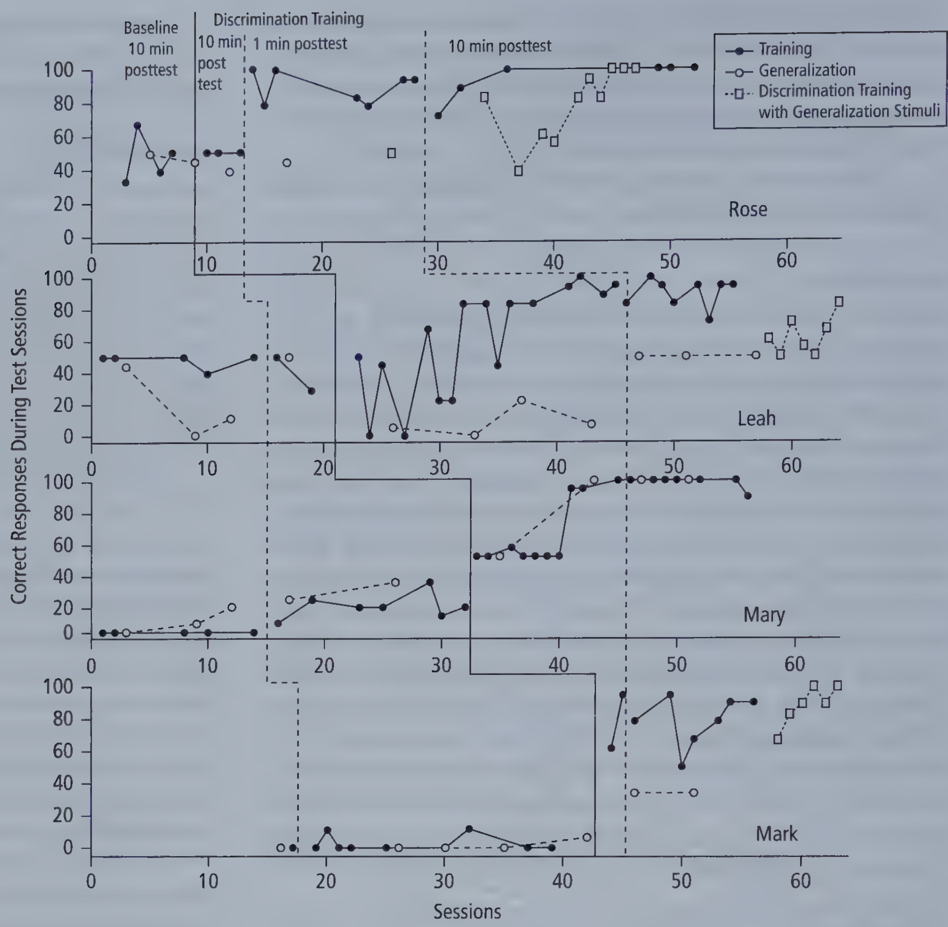

Figure 21.3 The percentage of correct responses during test sessions conducted after baseline, discrimination training, and generalization sessions for three children with autism.

SUMMARY

Imitation

1. Imitation entails four criteria: (a) The imitative behavior is occasioned by another person's model of the behavior (or symbolic representation thereof), (b) the imitative behavior has formal similarity with the model, (c), the imitative behavior follows the modeled behavior closely in time, and (d) the model is the primary controlling variable for the imitative behavior.

2. A model is a live or symbolic demonstration of the target behavior that shows the learner exactly what to do.

3. Formal similarity occurs when the imitator's behavior physically resembles the model and is in the same mode.

4. A brief latency between the model and the learner's behavior is an important feature of imitation.

5. Most instances of *delayed imitation* may be better understood with other behavioral principles and processes.

6. The most important property defining imitation is the controlling relation between a model's demonstration and a learner's performance of topographically similar behavior.

7. Imitation training is a systematic, research-based set of steps for teaching a non-imitative learner to imitate models of novel behaviors.

8. Generalized imitation refers to a learner imitating a wide variety of unprompted, untrained, non-reinforced modeled behaviors in different settings and situations.

9. Striefel's (1974) imitation training protocol for practitioners has the following components: (a) assess, and teach if necessary, prerequisite skills for imitation training; (b) select models for training; (c) pretest; (d) sequence models for training; and (e) conduct imitation training.

10. Guidelines for imitation training include the following:
    - Keep sessions active and brief.
    - Reinforce both prompted and imitative responses.
    - Pair verbal praise and attention with tangible reinforcers.
    - If progress stalls, back up and move ahead slowly.
    - Fade out verbal response prompts and physical guidance.

- Measure and record the learner's performance and review the data after each session.
- Terminate imitation training when the learner meets specified performance criteria such as: imitates the first presentations of five consecutive novel models across three sessions, imitates several untrained behavior chains (e.g., washing hands, brushing teeth, fingerspelling).

Modeling

11. Modeling is a behavior change strategy in which learners acquire new skills by imitating demonstrations of the skills by live or symbolic models.

12. Video modeling is a technique that involves the demonstration of desired behaviors through visual representations of the behavior.

13. In video self-modeling, the learners observe a video of themselves successfully performing the target behavior and imitates their self-model.

14. The effectiveness of modeling may be enhanced by:

- Models with characteristics similar to those of the learner.
- Models the learner considers to have prestige or social status.
- Models' emphasis on critical aspects of the target behavior.
- Instructions orienting and prompting the learner to attend to the model.
- Model demonstrating the target behavior in an authentic context.
- Rehearsal and feedback.
- The learner observing the model receiving reinforcement for the target behavior; the learner receiving reinforcement for imitating the target behavior.

Observational Learning

15. Observational learning entails another person's behavior and its consequence(s) and using that information to determined whether or not to imitate the behavior. Observational learning typically involves imitation but does not require it.

16. Three requisite skills are central to developing an observational learning repertoire: attending, imitating, and discriminating. If any of the skills are lacking, they can be taught separately and then combined.

KEY TERMS

generalized imitation
imitation
imitation training
modeling
observational learning
video modeling
video self-modeling

MULTIPLE-CHOICE QUESTIONS

1. With an understanding of the imitation process, applied behavior analysts can use imitation as an intervention to:

a. Eliminate old behaviors

b. Evoke new behaviors

c. Create teaching sequences

d. Reinforce appropriate behaviors

Hint: (See "Introduction to the chapter")

2. The controlling variable for an imitative behavior is:

a. An operative behavior

b. An imitative response chain

c. A model

d. A pre-task

Hint: (See "Imitation Defined")

3. Learning to purchase a soda from a vending machine by first watching someone else purchase a soda would be an example of:

a. Planned echoic stimuli

b. Unplanned echoic stimuli

c. Planned models

d. Unplanned models

Hint: (See "Imitation Defined")

4. When a child picks up a fork immediately after observing her father pick up a fork, this imitative behavior has:

a. Planned similarity

b. Unplanned similarity

c. Formal similarity

d. Informal similarity

Hint: (See "Imitation Defined")

5. Regardless of the behavior modeled, the objective of imitation training is for the learner to do what?
   a. What the model does
   b. What the trainer asked or commanded
   c. What behavior best fits the situation
   d. What behavior will receive reinforcement

   Hint: (See "Imitation Training")

6. Potential learners cannot imitate if they do not have this prerequisite skill:
   a. The behavior in their repertoire
   b. Attending to the model
   c. Decrease in problem behavior
   d. Ability to define the behavior

   Hint: (See "Imitation Training")

ESSAY-TYPE QUESTIONS

1. Four behavior environment relations functionally define imitation. What are they and why must each occur?

   Hint: (See "Imitation Defined")

2. A learner has played the game "Simon Says" many times in the past (left foot up, right foot up, left hand up, right hand up, etc.). During a game of "Simon Says", the trainer raises his right hand up without saying "Simon Says"; immediately after this model, the learner raises his hand. Is this an imitative behavior? Explain your answer.

   Hint: (See "Imitation")

3. During imitation training, if a learner fails to respond, what should a trainer do and how will this help to increase the potential for imitation learning?

   Hint: (See "Imitation Training")

NOTES

1. Before using food as a reinforcer, practitioners should determine the learner has no medical conditions that might preclude delivering food as a reinforcer (e.g., food allergies, swallowing difficulties) and should obtain permission from parents/guardians.

CHAPTER 22

Shaping

LEARNING OBJECTIVES

- Define and provide examples of shaping.
- Explain the process of shaping in terms of the behavioral contingencies used.
- Differentiate between shaping across different and within the same response topographies.
- Explain ways in which the efficiency of shaping can be increased.
- State the guidelines for implementing shaping effectively.

An Amazing Display!

In the summer of 1955 I was exploring some simple schedules of reinforcement in normal preschool children, using a variety of contingently delivered trinkets and bits of candies and cookies. The research was being conducted in a newly designed and equipped trailer laboratory at the University of Washington. In the far wall of the laboratory room as one entered was a large one-way glass, and beneath it a lever for responding (actually an O'Cedar mop handle). Above the lever was a recessed light bulb and below the lever was a small opening for delivering "goodies."

A child's responses on the lever were carried to a circuit which was programmed so that each reinforced response was accompanied by a light flash and a short buzz from the dispenser motor, indicating that a goodie was being delivered. The experimenter operated behind the wall with the one-way glass and apparatus.

One day I invited Bill Verplanck, a visiting professor in the Department of Psychology at the University of Washington, to join me in observing the performances of the children. He was impressed with what he saw: children responding in a fairly orderly fashion to fixed and variable ratio and interval schedules of reinforcement.

About halfway through the session, Verplanck suggested that we explore the shaping of operant behavior. We decided to see whether we could establish pulling the cord of the window shade on the window at the far side of the room, which was about fourteen feet away from the wall where the lever was situated. The procedure consisted of hand-shaping successive approximations to the final task, i.e., reinforcing getting off the chair, moving farther and farther away from the lever, raising the hand, grasping and then pulling on the window shade cord. Initial movements away from the lever were a bit slow in developing because each time the child was reinforced for moving away, he had to turn back or run back to get the goodie lodged in the receptacle. In a relatively short time, however, the response was well established: After snatching up a goodie, the child would run across the room, pull on the shade cord, and as soon as he heard the motor buzz, he would dash back to the receptacle and retrieve the goodie.

This was an amazing display! . . . Delivering reinforcers contingent on the topography of successive behaviors clearly showed how new operant behavior—any kind of new operant behavior—is probably established. I had just witnessed a dramatic demonstration of what we had for years been telling our students in introductory psychology, namely, that the implication of a scientific analysis of behavior is prediction and control of individual behavior.

—Adapted from "In Memoriam: Sidney W. Bijou, 1908–2009," by M. Dougher, 2009, *The Behavior Analyst*, pp. 363–364. Originally appeared in *Behavior Modification: Behavioral Approaches to Human Problems*, by W. H. Redd, A. L. Porterfield, and B. L. Andersen, 1978. New York: Random House. Used with permission.

Shaping is used in numerous situations to help learners acquire new behaviors. Wolf, Risley, and Mees (1964), for example, employed shaping in an applied setting to increase eyeglass wear for a child who was in danger of losing his eyesight if he did not wear corrective lens regularly. Athens, Vollmer, and St. Peter Pipken (2007) used shaping to improve the academic behavior of students with speech, language, and learning disabilities. Researchers and trainers have used shaping to teach functional behavior to animals (e.g., walking horses into a trailer without injury to the horses or the attendants), for appeal or utility purposes (e.g., teaching porpoises to execute show routines), for humanitarian reasons (e.g., conducting mine sweeping operations in formerly embattled combat areas), for security reasons (e.g., sniffing out explosives in airports, terminals, or high-traffic public venues), for medical assessments (e.g., detection of tuberculosis or necrotic tissue), and for assisting animals to remain calm during immunization protocols

and dental examinations and procedures (Poling et al., 2017; Pryor & Ramirez, 2014).

Depending on the complexity of a given behavior, or the gap between the learner's present level of performance and the desired target (terminal) behavior, shaping may require numerous successive approximations before the terminal behavior is achieved. Acquiring the terminal behavior with respect to time, trials, or direction is seldom predictable, immediate, or linear. It is possible that a learner—human or animal—might emit a closer approximation to the terminal behavior that a practitioner fails to detect and reinforce. In this situation, achievement of the terminal behavior will be delayed. However, if a systematic approach is used—that is, if each instance of a closer approximation to the terminal behavior is detected and reinforced while simultaneously placing prior behaviors on extinction—progress can be attained more quickly.

Although shaping a behavior can be time-consuming, it is an important tactic for teaching new behaviors (Fonger & Malott, 2018). Shaping should be in every behavior analyst's repertoire, especially in those instances where it is unlikely that novel target behaviors will be learned by following instructions, gaining incidental exposure, or providing models, physical cues, or verbal prompts.

This chapter defines shaping, differential reinforcement, and successive approximations; presents examples of how to shape behavior across and within different response topographies; and suggests ways to improve shaping efficacy. Clicker training is illustrated as a method that trainers use to shape new behaviors in animals and humans. Next, emerging applications of shaping, and how shaping can be applied to large-scale social and humanitarian endeavors, is presented. Finally, we provide guidelines for implementing shaping and conclude the chapter with "how to learn to shape behavior."

SHAPING DEFINED

Shaping consists of a three-part process whereby the analyst (a) detects a change in the learner's environment, (b) makes a discriminated judgment about whether that change is a progressively closer approximation to a terminal behavior of interest; and then (c) differentially reinforces that closer successive approximation. In short, **shaping** is defined as the differential reinforcement of successive approximations toward a terminal behavior. Detecting means that the shaper must use one or more of his or her physical senses to see, hear, or otherwise note that a change has occurred. Discriminated judgment means that the shaper must answer the following question: "Is what I just saw (or heard) a closer approximation to the desired terminal behavior or not?" **Differential reinforcement**, as applied in shaping, refers to presenting an unconditioned or conditioned reinforcer only to those emitted members of a response class that share a specified dimension or quality, while placing all other emitted response class members on extinction.[1]

In other words, the shaper, after detecting a change, must decide if that change is in the direction of an ever-evolving nearer approximation to the desired terminal behavior. If so, the analyst reinforces it immediately. If, after detecting a change, the analyst deems that the change occurred, but that it was not a closer approximation to the terminal behavior, then that previously emitted behavior is placed on extinction, meaning the analyst does not reinforce it.

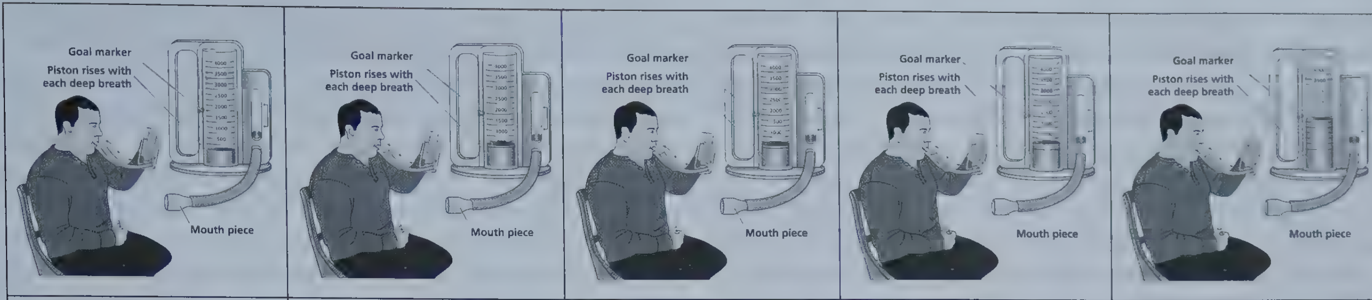
For example, assume that a respiratory therapist (RT) is charged with increasing the lung capacity of a patient recovering from pneumonia. She uses a spirometer, which measures lung capacity volume in milliliters (ml). The physician directing the treatment sets the patient's goal for 1750 ml, but the patient's present lung volume breathing behavior registers only 250 ml (i.e., a volume gap of 1500 ml). To use shaping, the RT first closely observes the patient to note the occurrence of a breathing volume change—any change. If any progressive breathing attempt exceeds 250 ml by any volume level (e.g., 250.01, 251, 255 ml) praise is delivered ("Well done, Yuri! That's higher!"). Any lower volume inhalation response level is placed on extinction.[2] Figure 22.1 shows a series of four initial trials illustrating this process as the patient works his way toward his goal.

Behavior analysts should not be deceived, however, by the apparent *step-wise* progression of improved breathing levels in Figure 22.1 (e.g., 300 ml, 325 ml, 500 ml). These levels were arbitrarily provided as a pedagogical illustration. Shaping, in its procedurally accurate application, is absolutely not a step-wise, fixed-gradient process that would require the patient to go from 250 ml to 300 ml to 350 ml and so on upward to the goal of 1750 ml. Any breathing behavior that moved the volume indicator level incrementally higher toward the physician-directed goal of 1750 ml (say, 250.1 ml to 276.5 to 339, etc.) would meet the criterion of being a successive approximation to 1750 ml and is reinforced. Any attempts lower than an already established higher level would be placed on extinction.

In *Science and Human Behavior*, Skinner (1953) presented the concept of shaping with an analogy:

> Operant conditioning shapes behavior as a sculptor shapes a lump of clay. . . . The final product seems to have a special unity or integrity of design, but we cannot find a point at which this suddenly appears. In the same sense, an operant is not something which appears full grown in the behavior of the organism. It is the result of a continuous shaping process. (p. 91)

Through careful and skillful manipulation of the original, undifferentiated lump of clay, the artisan keeps some aspects of the clay in its primary location, cuts other pieces away, and reforms and molds still other sections so that the form is slowly transfigured into the final sculpted design. Similarly, the skillful practitioner shapes novel forms of behavior from responses that initially may bear little resemblance to the final product. To restate, a practitioner using shaping differentially reinforces successive approximations toward a terminal behavior, while simultaneously placing on extinction attempts that do not progress toward the terminal behavior. The end product of shaping—*a terminal behavior*—can be claimed when the topography, rate, latency, duration, interresponse time, or magnitude of the target behavior reaches a predetermined criterion level (e.g., the physician-determined 1750-ml lung capacity level in our example). The two key procedural components of



Baseline trial: (250 ml). The patient's current breathing level.	**First attempt after baseline:** (300 ml). Reinforcement delivered. Had this attempt been any level lower than 250 ml, even fractionally, that breathing response would have been placed on extinction.	**Second attempt after baseline:** (325 ml). Reinforcement delivered. Had this attempt been any level higher than 300 ml, even fractionally, S^R would have been delivered. However, had this attempt been any lower than 300 ml, that attempt would have been placed on extinction.	**Third attempt after baseline:** (500 ml). Reinforcement delivered. Had this attempt been any level higher than 325 ml, even fractionally, S^R would have been delivered. However, had this attempt been any lower than 325 ml, that attempt would have been placed on extinction.	**Future attempts** continue in like fashion until the 1750 ml is attained. That is, breathing attempts are differentially reinforced. Higher levels are reinforced. Lower levels are placed on extinction.

Figure 22.1 Illustrates the process by which a respiratory therapist (a) detects a change in breathing volume, (b) makes a judgment about whether that change is a successive approximation in the direction of the terminal behavior (i.e., 1750 ml); and (c) differentially reinforces that closer successive approximation.

shaping—differential reinforcement and successive approximations—are presented next.

Differential Reinforcement

> *When a heavy ball is thrown beyond a certain mark, when a horizontal bar is cleared in vaulting or in jumping, when a ball is batted over the fence (and when, as a result, a record is broken or a match or game won), differential reinforcement is at work.*
>
> —B. F. Skinner (1953, p. 97)

To reiterate, differential reinforcement is a procedure in which reinforcement is delivered for responses that share a predetermined dimension or quality, and reinforcement is withheld for responses that do not demonstrate that quality (i.e., these responses are placed on extinction). Differential reinforcement has three fundamental effects: (a) Responses within a response class similar in function to those that have been reinforced in the past are more likely to reoccur; (b) responses resembling the unreinforced members are not as likely to reoccur (i.e., these responses undergo extinction); and (c) when responses are unreinforced and undergo extinction, extinction-induced variability may occur. **Extinction-induced variability** is the phenomenon of non-reinforcement of a response class whereby a temporary increase in the *changeability* of the response class topography occurs, and which may produce, by chance alone, a closer approximation to the terminal behavior. Extinction-induced variability addresses a change in the *form* of the response, whereas extinction burst addresses a change in the *rate* of the response.

When differential reinforcement is applied consistently within a response class, its triple effect results in a new response class composed primarily of responses sharing the characteristics of the previously reinforced subclass. This emergence of a new response class is called **response differentiation**. Catania (2013) provides a succinct description of how extinction-induced variability works with respect to establishing response differentiation.

> Shaping is based upon *differential reinforcement*. At successive stages, some responses are reinforced and others aren't. In addition, the criteria for differential reinforcement change as responding changes, in *successive approximations* to the response to be shaped. The property of behavior that makes shaping effective is that behavior is variable. No two responses are the same, and reinforcement of one response produces a spectrum of responses, each differing from the reinforced response along such dimensions as topography (form), force, magnitude and direction. Of these responses, some are closer to the response to be shaped than others and may be selected to be reinforced next. Reinforcing these responses produces still others, some of which may come even closer to the response to be shaped. Thus, reinforcement can be used to change the spectrum of responses until the one to be shaped occurs. (p. 114)

Successive Approximations

A **successive approximation** refers to the gradual and progressive criterion change for delivering reinforcement for

a behavior that is closer to the terminal behavior than the response it replaces. In other words, once a more incremental behavior occurs that resembles the terminal behavior more closely, reinforcement is delivered. When an initially reinforced response is established, the practitioner shifts the criterion for reinforcement to responses that are even a closer approximation of the terminal behavior. However, care must be applied in shifting the criterion. If the criterion is set too low, an excessive number of behaviors at the same behavior-performance level will be reinforced, stalling progress. If the criterion is set too high, extinction occurs and progress is thwarted (Hanley & Tiger, 2011; Noell, Call, & Ardoin, 2014). Skinner (1953) discussed the critical nature of successive approximations as follows:

> The original probability of the response in its final form is very low; in some cases, it may even be zero. In this way, we build complicated operants that would never appear in the repertoire of the organism otherwise. By reinforcing a series of successive approximations, we bring a rare response to a very high probability in a short time. This is an effective procedure because it recognizes and utilizes the continuous nature of a complex act. (p. 92)

Figure 22.2 illustrates a progression of successive approximations that might be used to shape drawing uniformly spaced horizontal lines. Inset 1 contains products of the learner's current repertoire (Skinner's "undifferentiated lump"). Inset 6 shows products of the desired terminal behavior. Shaping begins with the learner's current behavior; in this case, by detecting and then reinforcing longer scribbles (star-marked scribbles in Inset 1) and placing shorter scribbles on extinction. The resulting response differentiation produces a new response class (i.e., longer scribbles) (see Inset 2). The shaper shifts the criteria for reinforcement to more closely approximate the terminal behavior—in this example, longer scribbles that do not cross themselves. Insets 3 through 5 illustrate the new response classes that might emerge from differential reinforcement applied to each previous response class.

Shaping Different Dimensions of Performance

Behavior can be shaped along any of its measurable and malleable dimensions (see Table 22.1).

Let's focus on magnitude for a moment—the last dimension presented in Table 22.1—as it relates to teaching a child to talk within a conversational decibel range. Let us suppose a behavior analyst is working with a student who talks at such a low volume (e.g., below 45 decibels) that his teacher and peers have difficulty hearing him. Projected and planned intermediate approximations to 65 decibels (dB)—the amplitude of normal conversational speech—might be 45 dB, 55 dB, and ultimately 65 dB. With differential reinforcement, any response at or above 45 dB (45.1 dB, 47.7 dB, 50.3 dB) would be reinforced, whereas speaking responses that occurred at 45 dB or lower would be placed on extinction. With successive approximations, the criterion for reinforcement would be raised gradually and incrementally to 55 dB, and finally 65 dB. In effect, lower magnitude response levels are

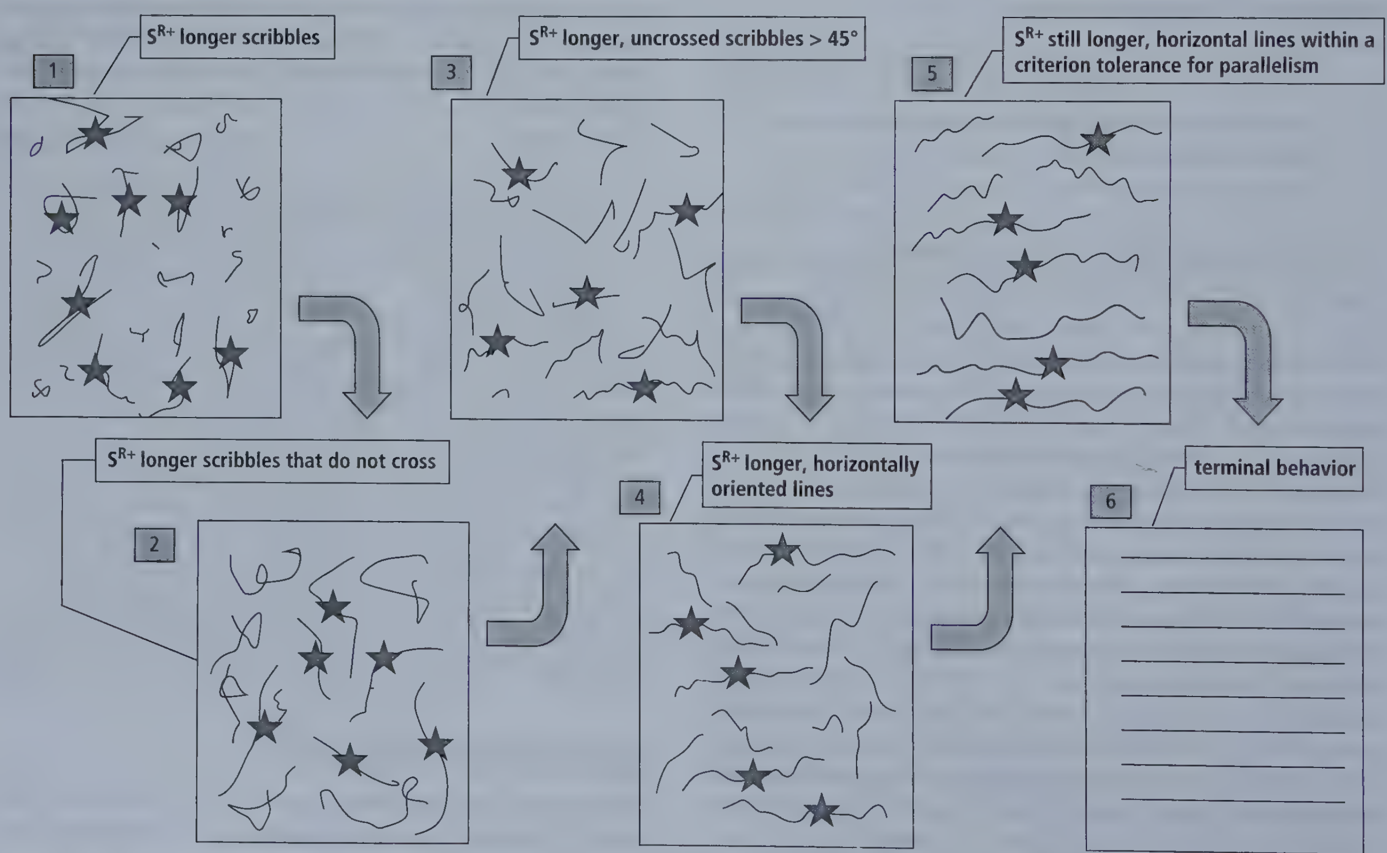


Figure 22.2 Shaping scribbles into uniformly spaced horizontal lines. Stars mark reinforced responses.

TABLE 22.1 Performance Dimensions That Can Be Shaped

Performance Dimension	Example
Topography (form of the behavior)	• Refining motor movements associated with a golf swing, throwing motion, or vaulting behavior. • Improving cursive or manuscript letter formation during handwriting exercises.
Rate (number of responses per unit of time)	• Increasing the number of problems completed per minute during a math seatwork assignment. • Increasing the number of correctly spelled and appropriately used words written per minute.
Latency (time between the onset of the antecedent stimulus and the occurrence of the behavior)	• Decreasing compliance time between a parental directive to "clean your room" and the onset of room-cleaning behavior. • Increasing the delay between the onset of an aggressive remark and retaliation by a student with severe emotional disabilities.
Duration (elapsed time from the onset of a response to its end point)	• Increasing the time a student stays on task. • Increasing the number of minutes of engaged study behavior.
Interresponse time (IRT)	• Reducing rapid eating by increasing the time (IRT) between food bites. • Reducing smoking by increasing the time (IRT) between lighting a cigarette.
Magnitude (response strength or force)	• Increasing the projected voice volume from 45 dB to 65 dB. • Increasing the required torque on a ratchet wrench from 20 foot pounds to 30 foot pounds.

not reinforced; higher magnitude responses (i.e., those that are successively above 45 dB, 55 dB, and 65 dB) are reinforced.

Fleece and colleagues (1981) used shaping to increase the voice volume of two children enrolled in a private preschool for students with physical and developmental disabilities. Baseline data were collected on voice volume in the regular classroom. Voice volume was measured on a 0- to 20-point scale, with 0 indicating that the child's voice level was inaudible, 10 indicating normal voice volume, and 20 indicating screaming. The shaping procedure consisted of having the children recite a nursery rhyme in the presence of a voice-activated relay device, whereby voice volume activated a light display. The intensity of the light corresponded to increased levels of voice volume: Higher voice volume produced a brighter light, and lower voice volume produced a dimmer light. The teacher shaped voice volume by increasing the sensitivity threshold of the relay device. Each raising of the volume level required to activate the light represented a successive approximation to the terminal volume.

Figure 22.3 shows an analysis of the children's improved performance. Also, the children's voice volume remained high after a 4-month period. Finally, according to anecdotal reports by school staff, the children's higher voice volume generalized to other settings beyond the classroom.

Applied behavior analysts can measure voice volume and apply differential reinforcement with advanced digital recording technology. Edgerton and Wine (2017), for example, used a digital tablet and app (Voice Meter Pro™) to measure the magnitude of a boy's utterances that frequently fell below conversational volume. The app displayed a thermometer-style gauge and three emoji faces (e.g., neutral, positive, and negative) that coupled visually signaled calibrated changes in voice magnitude with text prompts ("Speak up, I can't hear you!," "That's better," and "That's too loud!"). Although Edgerton and Wine did not use shaping—they implemented a package intervention of differential reinforcement, visual feedback, and corrective statements—the app they employed was adjustable and could be used in shaping voice volume.

SHAPING ACROSS AND WITHIN RESPONSE TOPOGRAPHIES

Shaping behavior across different response topographies means that selected members of a response class are differentially reinforced, whereas members of other response classes are placed on extinction. Many complex behaviors comprise component response classes, each class a necessary, but insufficient, contributor to the required performance. Speaking, for example, involves coordinated tongue and lip movements, speech sounds, one-word utterances, phrase or sentence productions, and so forth. When shaping behavior across different response topographies, the practitioner gradually increases the criterion of performance before delivering reinforcement.

Isaacs, Thomas, and Goldiamond (1960) reported a classic study showing how behaviors can be shaped across and within response topographies. They successfully shaped the vocal behavior of Andrew, a man diagnosed with catatonic schizophrenia, who had not spoken for 19 years despite numerous efforts to encourage speech production. Essentially, the shaping procedure was initiated when an astute psychologist noticed that Andrew's passive expression changed slightly when a package of chewing gum inadvertently dropped on the floor. Realizing that gum might be an effective reinforcer for building behaviors in the response class of talking, the psychologist selected speech production as the terminal behavior.

The next decision was to select an initial behavior to reinforce. Lip movement was chosen because the psychologist noted that slight lip movements had occurred in the presence of the pack of gum, and more important, lip movement was in the response repertoire of speech. As soon as lip movement was established by differential reinforcement, the psychologist waited for the next approximation of the terminal behavior. During this phase, lip movement alone was no longer reinforced; only lip movements with sound produced the reinforcement. When Andrew began making guttural sounds,

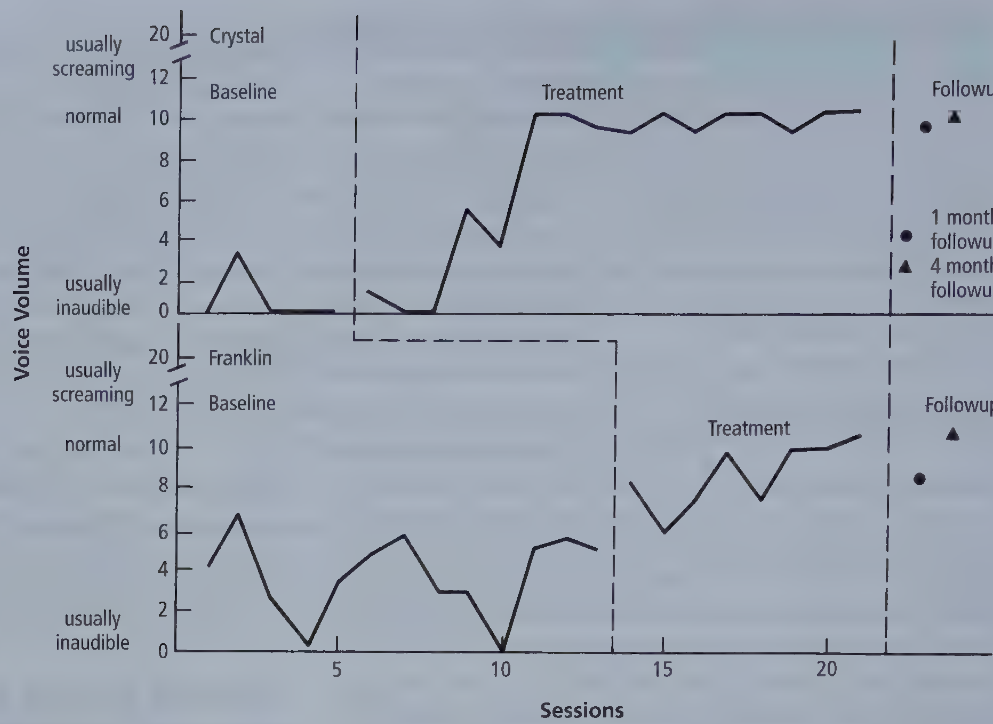

Figure 22.3 Voice-volume levels per session in the classroom generalization setting.

From "Elevation of Voice Volume in Young Developmentally Delayed Children via an Operant Shaping Procedure," by L. Fleece, A. Gross, T. O'Brien, J. Kistner, E. Rothblum, and R. Drabman, 1981, *Journal of Applied Behavioral Analysis, 14*, p. 354. Copyright by the Society for the Experimental Analysis of Behavior, Inc. Reprinted by permission.

vocalizations were differentially reinforced. Then the guttural sound itself was shaped (differential reinforcement within a response topography) until Andrew said the word *gum*. After the 6th week of shaping, the psychologist asked Andrew to say *gum*, to which Andrew responded, "Gum, please." During that session and afterward, Andrew went on to converse with the psychologist and others at the institution about his identity and background. In this powerful demonstration of shaping, after selection of the terminal behavior and the initial starting point, each member of the response repertoire was shaped by differential reinforcement of successive approximations to the terminal behavior.

Shaping a behavior within a response topography means that the form of the behavior remains constant, but differential reinforcement is applied to another measurable dimension of the behavior (Noell et al., 2014). To illustrate, let us suppose that in a college-level physical education class, the teacher is instructing the students on water rescue. Specifically, she is teaching them how to throw a life preserver a given distance to a person struggling in the water. Since the important skill in this activity is to throw the life preserver near the person (i.e., within reach), the physical education teacher might shape accurate tossing by reinforcing successive approximations to a toss of a given distance. In other words, each toss that is near the person (e.g., within 2 meters) will be praised, whereas tosses outside that range will not be reinforced. As students become more accurate, the area is reduced so that the terminal behavior—tosses within arm's length of the person—is achieved. In this case, the magnitude of the behavior is being shaped; the form of the toss remains the same. It is important to remember that the behavior being shaped is not tossing per se. What is being shaped by differential reinforcement is the desired dimension of tossing behavior within the response class, namely, the magnitude of tossing the preserver.

Beneficial Aspects of Shaping

Shaping uses a positive (i.e., reinforcing) approach to teach new behaviors. Also, it is systematic: Reinforcement is delivered consistently upon the occurrence of any successive approximations to the terminal behavior, whereas non-approximations are placed on extinction. Punishment or other aversive procedures are typically not involved in a shaping program. Further, shaping is usually combined with other established behavior change or behavior-building procedures (e.g., verbal prompts or chaining).

Harrison and Pyles (2013) combined verbal prompts with shaping to improve tackling by high school football players. Figure 22.4 shows the results for three players during football practice and game conditions where speed was gradually shaped from walking to jogging to running.

Shaping might further be combined with a chaining procedure when a given behavior within the chain is nonexistent or underdeveloped.[3] Suppose that a behavior analyst designed a seven-step task analysis to teach a child to tie his shoes. However, the child was unable to complete Step 5 in the task analysis. Shaping could be used in isolation to teach a closer approximation to that step. Once Step 5 was learned through shaping, chaining would continue with the rest of the steps in the task analysis sequence.

Limitations of Shaping

At least five limitations of shaping can be identified. Practitioners should be aware of these limitations and be prepared to deal with them if they arise.

1. Shaping new behavior can be time-consuming because numerous approximations may be necessary before the terminal behavior is achieved.

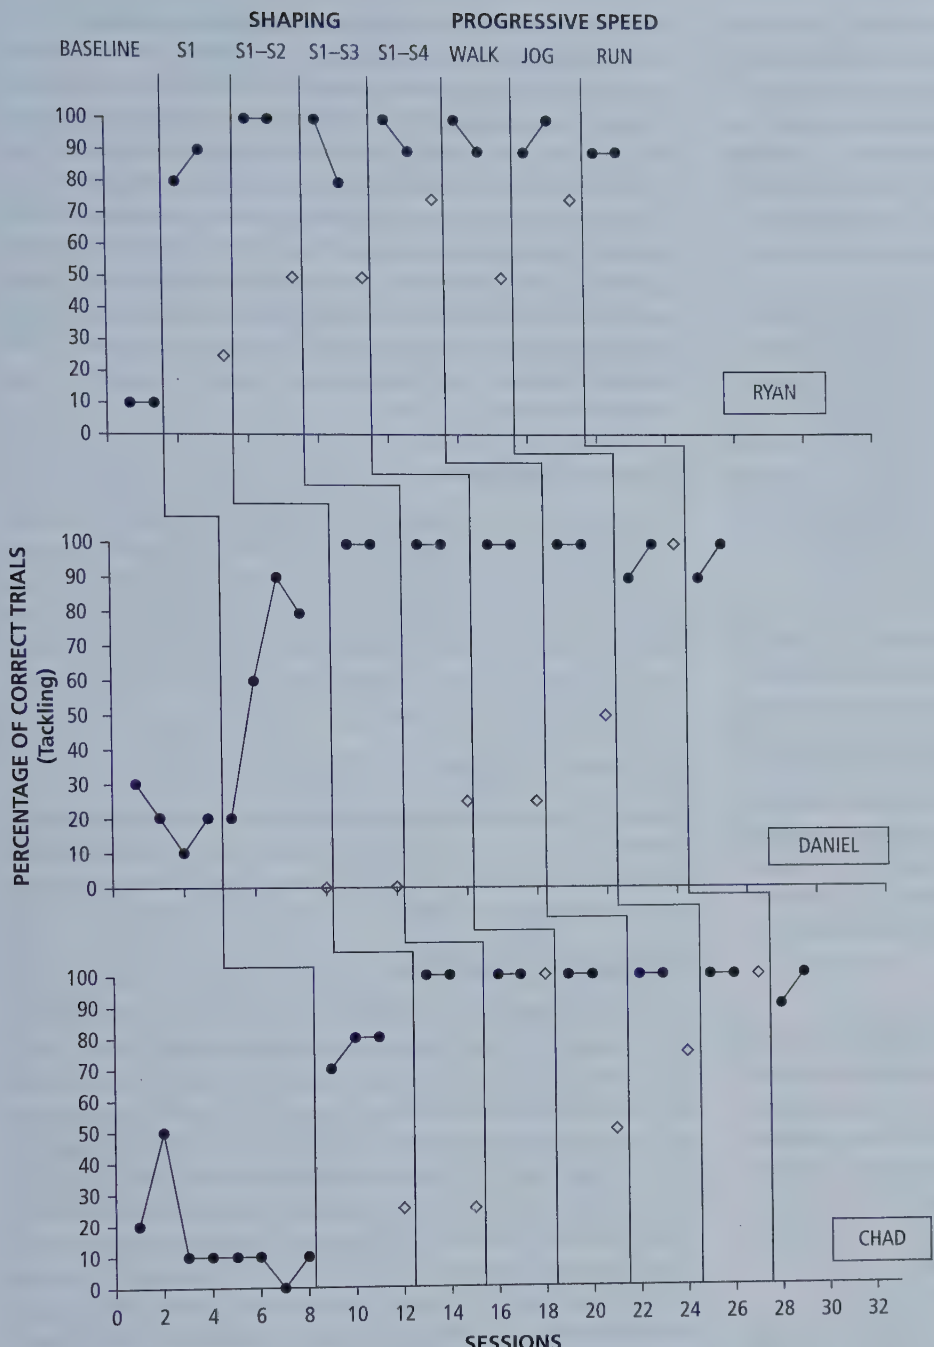

Figure 22.4 Percentage of correct tackling trials across all training phases. Open data points represent generalization probes of a complete tackle against a live ball carrier. (In the shaping procedure, S = skill.)

From "The Effects of Verbal Instruction and Shaping to Improve Tackling by High School Football Players," by A. H. Harrison and D. A. Pyles, 2013, *Journal of Applied Behavior Analysis, 46*(2), p. 521. Copyright by the Society for the Experimental Analysis of Behavior, Inc. Reprinted by permission.

2. Progress toward the terminal behavior is not always linear. That is, the learner does not always proceed from one approximation to the next in a continuous, progressive, or errorless sequence. Progress may be erratic. If the behavior is too irregular (i.e., not resembling a closer approximation to the terminal behavior), an approximation may need to be further reduced, allowing for more reinforcement and progress. The skill of the practitioner in noting and reinforcing the next smallest approximation to the terminal behavior is critical to the success of shaping. If the practitioner fails to reinforce responses at the next approximation—because of inexperience, preoccupation with other tasks, or neglect—the occurrence of similar responses may be few and far between. If reinforcement for performance at a given approximation continues longer than necessary, progress toward the terminal behavior will be impeded.
3. Shaping requires *continuous* monitoring to detect subtle changes in the learner's performance, indicating the next approximation to the terminal behavior. Many practitioners—for example, teachers in busy or demanding classrooms—are not able to monitor behavior closely enough to note small changes. Consequently, shaping may be conducted inappropriately or at least inefficiently.
4. Shaping can be misapplied. Consider the child trying to obtain her father's attention by emitting low-volume demands (e.g., "Dad, I want some ice cream."). The father

does not attend to the initial calls. As the child's attempts become increasingly unsuccessful (i.e., not reinforced), she may become more determined to gain her father's attention. In doing so, the number and magnitude of the calls may increase due to extinction-induced variability (e.g., "DAD, I WANT ICE CREAM!"). After listening to the crescendo of vocal demands, the father eventually provides the ice cream. The next time, however, it may come to pass that the child states what she wants in an even louder voice before gaining her father's attention. In this scenario, the father has differentially reinforced an ever-rising level of attention-getting behavior and shaped higher levels of call-outs for ice cream. Using this example as a backdrop, Skinner (1953) anticipated the result of such a scenario: "Differential reinforcement applied by a preoccupied or negligent parent is very close to the procedure we should adopt if we were given the task of conditioning a child to be annoying" (p. 98).

5. Harmful behavior can be shaped. For example, Rasey and Iversen (1993) showed that differential reinforcement shaped a rat's behavior to the point that the rat fell from the edge of a platform. By differentially reinforcing the rat for sticking its nose farther over the edge for food, the rat eventually fell off the ledge.[4] It is not difficult to speculate how adolescent games such as *Dare and Double Dare* and videos that capitalize on persons receiving differential reinforcement from peers or "likes" and encouraging comments on social media for increasingly higher levels of risk taking can lead to dangerous—and sometimes tragic—behavioral outcomes.

Shaping Versus Stimulus Fading

Shaping and stimulus fading change behavior gradually, albeit in much different ways. In shaping, the antecedent stimulus for the terminal behavior stays the same, while the response progressively becomes more differentiated. In stimulus fading, the opposite occurs: The antecedent stimulus changes gradually, while the response stays essentially the same.

INCREASING SHAPING EFFICIENCY

In addition to showing how behaviors are shaped across and within response topographies, the Isaacs and colleagues (1960) study illustrates another aspect of shaping—efficiency. During the early stages of the program, the psychologist waited for the next approximation of the behavior to appear before delivering the reinforcer. Since waiting can be time-consuming and wasteful, Isaacs and colleagues improved efficiency by using a verbal response prompt, "Say gum," after the sixth training session. Presumably, if the psychologist had not used a verbal prompt, several additional sessions would have been necessary before a successful outcome was achieved. Shaping may become more efficient by using a discriminative stimulus, physical guidance, imitative prompts, and/or a percentile schedule.

Discriminative Stimulus

A discriminative stimulus (S^D) may be combined with shaping. For example, when attempting to shape hand shaking as a greeting skill for an adult with developmental disabilities, the teacher might say, "Frank, hold out your arm." Scott, Scott, and Goldwater (1997) used a discriminative stimulus in the form of a vocal prompt ("Reach!") as a university-level pole-vaulter ran a path to plant his pole in the vault box. The prompt was designed to focus the vaulter's attention on extending his arms prior to take-off in the vault.

Kazdin (2013) suggested that priming a response using any of a variety of prompting mechanisms (S^Ds) can be helpful, especially if the individual's repertoire is weak and the likelihood of distinguishable successive approximations is low. "Even if the responses are not in the client's repertoire of responses, the priming procedure can initiate early response components and facilitate shaping" (p. 277).

Physical Guidance

The second way to enhance shaping is through physical guidance. In the hand shaking example with Frank, cited earlier, the teacher might tap his arm manually, assist Frank with holding out his arm, move his arm forward with light pressure in a hand shaking motion, or hold his arm firmly through the full motion. Any physical guidance prompt used to enhance or speed up shaping should later be faded.

Imitative Prompts

Using an imitative prompt to demonstrate arm extension (e.g., "Frank, hold out your arm like this.") may improve shaping's efficiency. As with physical guidance, any imitative prompt should ultimately be faded.

Percentile Schedules

Because shaping requires a skilled observer to (a) detect behavior changes, (b) apply differential reinforcement to ever-closer approximations to a terminal behavior, and (c) place non-approximations on extinction, shaping has been characterized as more "art than science" (Lattel & Neef, 1996). Galbicka (1994) stated that practitioners would benefit from moving from a *qualitative*-based, observer-detecting standard for determining if the next response in a shaping program should be reinforced to a *quantitative* standard. In his view, a percentile schedule enables more precise shaping procedures, allows implementation by multiple trainers across settings, reduces the time it takes to complete a shaping sequence, and quantitatively moves closer to Skinner's conception of shaping.

> Percentile schedules disassemble the process of shaping into its constituent components, translate those components into simple, mathematical statements, and then use these equations, with parameters specified by the experimenter or trainer, to determine what presently constitutes a criterional response and should therefore be reinforced. (p. 740)

Using a mathematical equation ($i.e., k=(m+1)(1-w)$) and a computer software program, a percentile schedule continually calculates and adjusts the criterion for reinforcement based on recent observations.

> In this equation, w denotes the density of reinforcement, and m is a fixed number of recent observations. The k

> parameter specifies what response value out of *m* most recently observed response values an upcoming response must exceed to satisfy the criterion for reinforcement. For example, with a *w* value of .5, a response meeting the criterion for reinforcement for a given observation will be observed half the time, offering a mixture of reinforcement and extinction of responses. An *m* value of 10 means that the 10 most recent observations are ranked according to their ordinal value from least to most, keeping the shaping procedure in touch with the individual's current repertoire. Solving the equation using these values gives a *k* value of 5.5. In most cases, it is easier to implement the percentile schedule by rounding the *k* value to a whole number. In the example, rounding *k* to 5 keeps the reinforcement density at approximately half of all responses and makes the criterion for reinforcement slightly less stringent than a larger *k* value. The *k* value of 5 denotes the observation ranked fifth among the 10 most recently observed and ranked observations is the value the current observation must exceed to meet the criterion for reinforcement. (Athens, et al., 2007, pp. 475–476)

Several applied studies have evaluated percentile schedules with respect to shaping smoking cessation (Lamb, Kirby, Morral, Galbicka & Iguchi, 2010; Lamb, Morral, Kirby, Iguchi, & Galbicka, 2004), increased duration of eye contact (Hall, Maynes & Reiss, 2009), and increased engagement with academic tasks (Athens et al., 2007). In a parametric study of the effectiveness of percentile schedules in shaping academic task engagement, Athens and colleagues (2007) compared three values of *m* (5, 10, and 20). Their findings indicated that the percentile schedule was most effective when a relatively large number of previous observations ($N = 20$) were taken into account. In discussing the limitations of their study and comparing findings with those of other studies, Athens et al. noted that while "the procedure appears to be promising," the "potential utility of a percentile schedule for clinicians and applied researchers remains to be seen" (p. 486).

We agree with Athens et al. to the extent that a percentile schedule is encouraging. However, for greater utility in applied settings, practitioners would need to be well versed in using their recommended mathematical equation and be proficient with using the computer software program in "real time." Also, whether a percentile schedule increases shaping's efficiency over conventional applications remains an empirical question. Additional experimental studies that examine efficiency as a dependent variable will contribute to establishing percentile schedules as a viable alternative to conventional applications.

CLICKER TRAINING

Pryor (1999) described **clicker training** as a science-based system for progressively shaping new behavior using positive reinforcement and extinction. The clicker is a handheld device that produces a clicking sound when a metal tab is pressed. Reinforcement is paired with the sound of the clicker so that the sound becomes a conditioned reinforcer. Initially used to shape dolphin behavior without physical guidance (Pryor & Norris, 1991), clicker training was later used with other animals (e.g., cats and horses) and ultimately with humans to shape such complex behaviors as airplane pilot skills (M. Pryor, 2005). Other researchers and practitioners (e.g., Poling et al., 2011a) have used clicker training as part of their overall shaping program to teach African giant pouched rats how to detect land mines.

> Clicker trainers focus on building behavior, not stopping behavior. Instead of yelling at the dog for jumping up, you click it for sitting. Instead of kicking the horse to make it go, you click it for walking. Then, click by click, you "shape" longer sits, or more walking, until you have the final results you want. Once the behavior is learned, you keep it going with praise and approval and save the clicker and treats for the next new thing you want to train. (Pryor, 2002, p. 1)

Figure 22.5 provides 15 tips for getting started with clicker training (Pryor, 2002).

EMERGING APPLICATIONS OF SHAPING

At least three emerging applications of shaping can be considered: using computers to teach shaping skills, combining shaping procedures with robotics engineering, and applying telemedicine technology to implement shaping and differential reinforcement programs in hard-to-access urban, rural, or remote settings.

Using Computers to Teach Shaping

Several options are currently available to teach shaping skills using computers, or a combination of specialized software with computer-based applications. For example, Sniffy the Virtual Rat is a computer-based, digitized animation of a white rat within a Skinner box. Students practice basic shaping on their own personal computers using this virtual simulation.

Acknowledging the practical limitations of teaching behavior analysis principles (e.g., shaping) interactively to a large student body, Shimoff and Catania (1995) developed and refined computer simulations to teach the concepts of shaping.[5] In their simulation *The Shaping Game*, four levels of difficulty (easy, medium, hard, and very hard) were programmed over a series of refinements. Beginning with easier tasks and advancing to the very hard level, students are taught to detect successive approximations to bar-pressing behaviors that should be reinforced, and those that should not. In still later versions, students are expected to shape the movement of the animated rat from one side of a Skinner box to another. Shimoff and Catania made a case for computer simulations when they stated, "Computers can be important and effective tools for establishing sophisticated behavior that appears to be contingency shaped even in classes that do not provide real (unsimulated) laboratory experience" (pp. 315–316).

Martin and Pear (2003) contended that computers might be used to shape some dimensions of behavior (e.g., topography) more quickly than humans because a computer can be calibrated

Figure 22.5 Pryor's 15 tips for getting started with the clicker.

1. Push and release the springy end of the clicker, making a two-toned click. Then treat. Keep the treats small. Use a delicious treat at first: for a dog or cat, little cubes of roast chicken, not a lump of kibble.
2. Click DURING the desired behavior, not after it is completed. The timing of the click is crucial. Don't be dismayed if your pet stops the behavior when it hears the click. The click ends the behavior. Give the treat after that; the timing of the treat is not important.
3. Click when your dog or other pet does something you like. Begin with something easy that the pet is likely to do on its own (ideas: sit, come toward you, touch your hand with its nose, lift a foot, touch and follow a target object such as a pencil or a spoon).
4. Click once (in-out). If you want to express special enthusiasm, increase the number of treats, not the number of clicks.
5. Keep practice sessions short. Much more is learned in three sessions of five minutes each than in an hour of boring repetition. You can get dramatic results, and teach your pet many new things, by fitting a few clicks a day here and there in your normal routine.
6. Fix bad behavior by clicking good behavior. Click the puppy for relieving itself in the proper spot. Click for paws on the ground, not on the visitors. Instead of scolding for making noise, click for silence. Cure leash-pulling by clicking and treating those moments when the leash happens to go slack.
7. Click for voluntary (or accidental) movements toward your goal. You may coax or lure the animal into a movement or position, but don't push, pull, or hold it. Let the animal discover how to do the behavior on its own. If you need a leash for safety's sake, loop it over your shoulder or tie it to your belt.
8. Don't wait for the "whole picture" or the perfect behavior. Click and treat for small movements in the right direction. You want the dog to sit, and it starts to crouch in back: Click. You want it to come when called, and it takes a few steps your way: Click.
9. Keep raising your goal. As soon as you have a good response—when a dog, for example, is voluntarily lying down, coming toward you, or sitting repeatedly—start asking for more. Wait a few beats, until the dog stays down a little longer, comes a little further, sits a little faster. Then click. This is called "shaping" a behavior.
10. When your animal has learned to do something for clicks, it will begin showing you the behavior spontaneously, trying to get you to click. Now is the time to begin offering a cue, such as a word or a hand signal. Start clicking for that behavior if it happens during or after the cue. Start ignoring that behavior when the cue wasn't given.
11. Don't order the animal around; clicker training is not command-based. If your pet does not respond to a cue, it is not disobeying; it just hasn't learned the cue completely. Find more ways to cue it and click it for the desired behavior. Try working in a quieter, less distracting place for a while. If you have more than one pet, separate them for training, and let them take turns.
12. Carry a clicker and "catch" cute behaviors like cocking the head, chasing the tail, or holding up one foot. You can click for many different behaviors, whenever you happen to notice them, without confusing your pet.
13. If you get mad, put the clicker away. Don't mix scoldings, leash-jerking, and correction training with clicker training; you will lose the animal's confidence in the clicker and perhaps in you.
14. If you are not making progress with a particular behavior, you are probably clicking too late. Accurate timing is important. Get someone else to watch you, and perhaps to click for you, a few times.
15. Above all, have fun. Clicker-training is a wonderful way to enrich your relationship with any learner.

and programmed with specific decision rules for delivering reinforcement. They further suggested that in medical application cases (e.g., amputees, stroke victims), minute muscle movements may go undetected by a human observer, but a microprocessor could be calibrated to detect shapeable responses. In their view, "Computers . . . are both accurate and fast and may therefore be useful in answering fundamental questions concerning which shaping procedures are most effective . . . computers may be able to shape at least some kinds of behavior as effectively as humans" (p. 133).

Combining Shaping with Robotics Engineering

Dorigo and Colombetti (1998) and Saksida, Raymond, and Touretzky (1997) have explored how shaping can be applied to robot training. Essentially, shaping is used as one method of programming robots to progress through initial, intermediate, and final goals to achieve more complicated sets of commands. According to Savage (1998):

> Given that shaping is a significant determinant of how a wide variety of organisms adapt to the changing

> circumstances of the real world, then shaping may, indeed, have potential as a model for real-world robotic interactions. However, the success of this strategy depends on a clear understanding of the principles of biological shaping on the part of the roboticists, and the effective robotic implementation of these principles. (p. 321)

Although Dorigo and Colombetti (1998) and Saksida and colleagues (1997) concede the difficulty of applying successive approximations to robots, this line of inquiry, combined with emerging knowledge on artificial intelligence, offers exciting prospects for the future.

Applying Telemedicine Technology to Implement Shaping and Differential Reinforcement Programs in Hard-to-Access Urban, Rural, or Remote Settings

Telemedicine technologies involve connecting host-institution training centers with off-site rural or remote settings through high-speed, Internet-based, interactive audio-video links. Each site—host and remote—is equipped with the appropriate computers, cameras, monitors, and routers to enable instantaneous two-way communications between trainers at the host site and trainees at the remote site.

These technologies, originally developed to provide consultation and assessment services to families living in rural or remote locations (Barretto, Wacker, Harding, Lee, & Berg, 2006), have been expanded to provide additional services in the form of functional analyses and interventions, including differential reinforcement procedures (Peterson, Volkert, & Zeleny, 2015). Not only have telemedicine/telehealth technologies been shown to produce effective results, but also the added cost savings with respect to travel time and efficiency of implementation bode well for wider implementation in emerging rural/remote locations in the future.

Over the past decade, new and exciting applications have been explored to enhance the human condition and to increase safety and improve public welfare. Applications that combine shaping with discrimination training have been reported in several general areas: detecting land mines (Edwards, Cox, Weetjens, Tewelde, & Poling, 2015; Poling et al., 2011a); uncovering contraband (Jezierski et al., 2014); searching for, and locating, humans trapped in simulated collapsed buildings (Edwards, La Londe, Cox, Weetjens, & Poling, 2016; La Londe et al., 2015); and detecting tuberculosis or necrotic tissue (Poling et al., 2011b; Poling et al., 2017). Poling et al. (2017), for example, reported that trained African giant pouched rats detected 2000 additional active tuberculous cases compared to cases that reported tuberculous using only traditional microscopic analysis for diagnosis.

Likewise, in the case of land mine detection, Poling et al. (2011a) incorporated shaping, clicker training, and differential reinforcement of African giant pouched rats, who, after training, successfully searched over 93,000 m^2 of land (i.e., approximately 23 acres),[6] locating upwards of 100 mines and other explosives. The rats were 100% accurate in discriminating buried land mines from other materials buried beneath the soil surface, a finding replicated by Edwards et al. (2015) with remarkable consistency.

It is worth noting that these field-based efforts provide stunning examples of how shaping can be combined with other procedures (namely, clicker and discrimination training) to help communities plagued by disease or the ravages of war to reclaim healthier and more productive lives.

SHAPING GUIDELINES

The practitioner should consider various factors before deciding to use shaping. First, assess the terminal behavior and the available resources. For example, assume that a fifth-grade teacher is interested in increasing the number of math problems performed by a student with learning disabilities. The student completes 5 problems per math period, with a range of 0 to 10 problems. If the student has the ability to check her performance independently at the end of the class period, shaping could be implemented whereby the number of correctly completed math problems per period would be differentially reinforced. Reinforcement would be presented for 5, 7, 9, and progressively more problems answered correctly per session.

Second, since shaping may require multiple approximations and additional trained personnel, the analyst should assess whether time constraints, staff issues, or lack of resources militate against the use of shaping.

Third, some behaviors seem to preclude the use of shaping. For instance, if the manager of a community-based organization (e.g., *Toastmasters International*) is interested in increasing the public-speaking repertoires of participants, prompting, modeling, or peer tutoring might be more efficient than shaping. That is, telling or showing the participant how to use a gesture, voice inflection, or a metaphor would likely be much faster than attempting to shape each of these presentation skills alone.

Finally, Pryor's original *Ten Laws of Shaping* (1999) have evolved over time into what is now termed *The Modern Principles of Shaping*. These principles can assist the practitioner in implementing shaping in applied settings (see Figure 22.6).

Select the Terminal Behavior

Practitioners often work with learners having multiple behavior challenges. Consequently, they must identify the highest priority behavior to change as quickly as possible. The ultimate criterion in this decision is the individual's expected independence after an intervention—that is, the likelihood of her attaining additional reinforcers from the environment (Brown, McDonnell, Snell, & Brown, 2016). For example, if a student frequently roams the classroom poking other students, taking their papers, and verbally harassing them, a shaping procedure might best begin with a behavior that is incompatible with roaming the room because of the utility it would have for the individual and the other students. In addition, if in-seat behavior is developed, the staff with whom the student interacts will likely notice and reinforce it. In this case, shaping should differentially reinforce longer durations of in-seat behavior.

Figure 22.6 Pryor's *The Modern Principles of Shaping.*

1. **Be prepared before you start.** Be ready to click/treat *immediately* when the training session begins. When shaping a new behavior, be ready to capture the very first tiny inclination the animal gives you toward your goal behavior. This is especially true when working with a prop such as a target stick or a mat on the ground.
2. **Ensure success at each step.** Break behavior down into small enough pieces that the learner always has a realistic chance to earn a reinforcer.
3. **Train one criterion at a time.** Shaping for two criteria or aspects of a behavior simultaneously can be very confusing. One click should not mean two different criteria.
4. **Relax criteria when something changes.** When introducing a new criterion or aspect of the skill, temporarily relax the old criteria for previously mastered skills.
5. **If one door closes, find another.** If a particular shaping procedure is not progressing, try another way.
6. **Keep training sessions continuous.** The animal should be continuously engaged in the learning process throughout the session. He should be working the entire time, except for the moment he's consuming/enjoying his reinforcer. This also means keeping a high rate of reinforcement.
7. **Go back to kindergarten, if necessary.** If a behavior deteriorates, quickly revisit the last successful approximation or two so that the animal can easily earn reinforcers.
8. **Keep your attention on your learner.** Interrupting a training session gratuitously by taking a phone call, chatting, or doing something else that can wait often causes learners to lose momentum and get frustrated by the lack of information. If you need to take a break, give the animal a "goodbye present," such as a small handful of treats.
9. **Stay ahead of your learner.** Be prepared to "skip ahead" in your shaping plan if your learner makes a sudden leap.
10. **Quit while you're ahead.** End each session with something the learner finds reinforcing. If possible, end a session on a strong behavioral response, but, at any rate, try to end with your learner still eager to go on.

From K. Pryor & L. Chamberlain, 2016, https://www.clickertraining.com/files/the-modern-principles-of-shaping-SF-edits.pdf.

It is also important to define the terminal behavior precisely. For example, a behavior analyst might want to shape the appropriate sitting behavior of an individual with severe intellectual disabilities. To do so, sitting might be defined as being located upright in the chair, facing the front of the room with buttocks against the bottom of the chair and back against the chair rest during a 15-min morning activity. Using this definition, the analyst can determine when the behavior is achieved, as well as what does not constitute the behavior—an important discrimination if shaping is to be conducted efficiently (e.g., the student might be half in and half out of the seat, or the student might be in the seat but turned toward the back of the room).

Determine the Criterion for Success

After identifying the terminal behavior, the practitioner should specify the criterion for success. Here, the practitioner decides how accurate, fast, intense, or durable the behavior must be before it can be considered shaped. Several measures can be applied to establish a criterion of success. Some of the more common include rate, magnitude, and duration. Depending on the terminal behavior, any or all of these dimensions can be used to assess achievement. For instance, a special education teacher might shape rate performance in solving mathematics calculations problems that would proceed from the student's current level of performance (say, half a problem per minute) to a higher rate (e.g., four problems per minute).

Norms for success can be determined by measuring the behavior in a similar peer group, consulting established norms in the literature, or complying with international standards for accuracy. For instance, norms and guidelines for reading rate by grade level (Kame'enui, 2002), physical education skills for children by age group (President's Council on Physical Fitness, 2016), homework guidelines per grade level (Heron, Hippler, & Tincani, 2003), or accepted standards for land mine detection (Poling, 2011a; Edwards et al., 2015) can be referenced to validate progress toward, or the achievement of, the terminal behavior.

In the earlier illustration, the criterion for success could be the student's sitting in her seat appropriately 90% of the time during the morning activity for 5 consecutive days. In this example, two criteria are specified: the percentage of acceptable sitting behavior per session (i.e., 90%) and the number of days that the criterion must be met to establish the behavior (i.e., 5 consecutive days). Poling and colleagues (2011a) used multiple criteria for determining success with respect to the accurate performance trials per day, and consecutive days at increasingly higher performance levels.

Assess the Response Repertoire

There is a two-fold reason for assessing response repertoires. First, having established the desired terminal behavior, it is important to ascertain the "behavioral gap" between the current level of behavior and the desired target behavior. In our respiratory therapy example cited earlier, that gap constituted 1500 ml of volume difference (i.e., goal was 1750 ml; present level was 250 ml). Second, assessing the response repertoire may help to project the successive approximations that might be emitted in the shaping sequence. When approximation behaviors

are known—or anticipated—the practitioner is in a better position to observe and reinforce an approximation when it occurs. However, the practitioner must recognize that projected approximations are guesstimates of behaviors. In actuality, the learner may emit behaviors that are merely approximations of these projections. The practitioner must be able to make the professional judgment that the previously emitted behavior either is, or is not, a closer approximation to the terminal behavior than the behaviors that occurred and were reinforced in the past. Galbicka (1994) provides a guideline for the behavior analyst with respect to assessing an existing response repertoire.

> The successful shaper must carefully ascertain characteristics of an individual's present response repertoire, explicitly define characteristics the final behavior will have at the end of training, and plot a course between reinforcement and extinction that will bring the right responses along at the right time, fostering the final behavioral sequence while never losing responding altogether (p. 739).

The relevant approximations across or within a response repertoire can be analyzed in several ways. First, practitioners can consult experts in the field to determine their views on the proper sequence of approximations for a given behavior (Brown et al., 2016). For example, teachers who have taught three-digit multiplication for several years can be consulted to learn their experiences with prerequisite behaviors for performing this type of calculation task. Second, as stated earlier, normative data from published studies may be used to provide an estimate of the approximations involved. Third, a digital recording can be used to analyze the component behaviors. A slow-motion digital replay would help the practitioner to see motion that might be undetectable in an initial faster-moving live performance, but become detectable as the practitioner becomes skilled with observing it. Finally, the practitioner can perform the target behavior himself, carefully noting the discrete behavioral components as he produces them.

The ultimate determination of the approximations, the approximation order, the duration of time that reinforcement should be delivered at a given approximation, and the criteria for skipping or repeating approximations rests with the skill and the judgment of the practitioner. Ultimately, the learner's performance should dictate when approximation size should be increased, maintained, or decreased, making consistent and vigilant monitoring by the practitioner essential.

Identifying Behaviors to Reinforce

At the outset of any shaping session, the shaper must observe the participant closely to detect any movement, slight though it might be, in the direction of the desired terminal behavior. At the instant that this behavior occurs, reinforcement is delivered. So, if an occupational therapist was shaping the terminal behavior of a toddler to eat a bowl of potatoes with a spoon, any hand or finger movement, even a twitch, would be reinforced. Subsequently, successive hand or finger movements toward the spoon would be reinforced. Thereafter, movements that successively touched the spoon, grasped the spoon, raised the spoon, directed the lifted spoon toward her mouth, and so on, would be reinforced, whereas other behaviors would undergo extinction. Conversely, the analyst would *not* set an initial criterion of raising the spoon out of the bowl. To set the behavior criterion at this level would be counterproductive, as raising-the-spoon behavior may not be in the child's present repertoire.

Eliminate Interfering or Extraneous Stimuli

Eliminating distractions during shaping enhances the process. For example, if a parent is interested in shaping one dimension of her young daughter's dressing behavior (e.g., the rate of dressing before school), but decides to begin the shaping procedure in her bedroom, where cartoons are playing on a morning television show, the shaping program may not be successful. The cartoons will compete for the daughter's attention. It would be more efficient to choose a time and a location where such sources of distraction can be reduced or eliminated.

Proceed Gradually

The importance of proceeding toward the terminal goal gradually cannot be overemphasized. The practitioner should anticipate changes in the rate of progress and be prepared to go from approximation to approximation as the learner's behavior dictates. Each new occurrence of a successive approximation to the terminal behavior must be detected and reinforced. If not, shaping will be, at worst, unsuccessful or, at best, haphazard, requiring much more time. Furthermore, the occurrence of a behavior at a given approximation does not mean the next response that approximates the terminal behavior will be immediately or accurately produced.

The practitioner must also be aware that many trials may be required at a given approximation before the subject can advance to the next approximation. Figure 22.7 illustrates this point well. Scott and colleagues (1997) found that the percentage of correct arm extensions by the pole-vaulter decreased initially as the height of the bar was raised. Whereas a 90% correct arm extension was noted at the initial height, the vaulter's correct performance typically dropped to approximately 70% each time the bar was raised. After successive attempts at the new height, the 90% correct criterion was re-established.

Limit the Number of Approximations at Each Level

Just as it is important to proceed gradually from approximation to approximation, it is equally important to ensure that progress is not impeded by offering too many trials at a given approximation. This may cause the behavior to become firmly established, and because that approximation has to be extinguished before progress can begin again (Catania, 2013), the more frequently reinforcement is delivered at a given approximation, the longer the process can take. In general, if the learner is progressing steadily, reinforcement is being delivered at the correct pace. If numerous mistakes are being made, or behavior ceases altogether, the criterion for reinforcement has been raised too quickly. Finally, if the performance stabilizes at a certain level, the pace of shaping is too slow. Practitioners may experience all three of these conditions while shaping. Therefore, they must be vigilant and adjust the next successive approximation and reinforcement schedule as necessary.

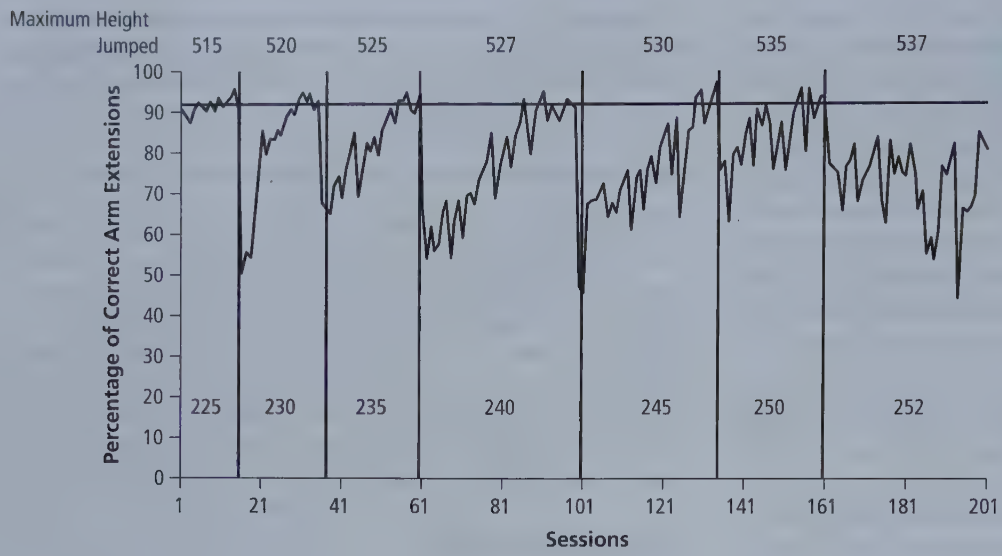

Figure 22.7 Percentage of correct arm extensions at seven different heights. The numbers contained within each criterion condition refer to the height of the photoelectric beam.

Continue to Reinforce When the Terminal Behavior Is Achieved

When the terminal behavior is demonstrated, and reinforced, it is necessary to continue to reinforce it over time; otherwise, the behavior will extinguish, and performance will return to a lower level. Reinforcement must continue until the criterion for success is achieved, and a maintenance schedule of reinforcement is established.

LEARNING TO SHAPE

Reading the narrative, illustrations, rules, and guidelines, such as those presented in this chapter, can help an emerging analyst become a skilled behavior shaper. Such reading is necessary, but not sufficient, with respect to gaining proficiency as a "shaper." The best way to learn how to shape behavior proficiently is to practice shaping behavior! So, how does one go about practicing shaping behavior? Let's explore a few options that can be arranged whether you prefer to practice by yourself, with a partner, or in a group. Whatever the arrangement, however, seek the advice and direction of a skilled behavior shaper who can provide directive feedback and reinforcement during your training.

By Yourself

You could practice trying to shape a simple terminal behavior with an animal (e.g., teaching a rat to press a bar, a pigeon to peck a disc, or a dog to follow a "sit" command). The simpler the terminal behavior and the more "controlled" the setting, the better (e.g., a lab, a quiet room away from distractions). Previewing a well-conducted shaping session on a YouTube video that resembles the behavior you are trying to shape, or consulting with a skilled colleague using Skype or FaceTime, might expedite the learning process for you.

Alternatively, where access to animals, controlled laboratories, or cooperative teachers is limited, consider using a simulation program such as Sniffy the Virtual Rat (Alloway, Wilson, & Graham, 2005). Sniffy, as mentioned earlier, is a computer-based, digitized, virtual animation of a white rat that can be accessed on a personal computer, which allows one to practice basic shaping at any convenient time or location.

With a Partner

Choose a friend or colleague and play "*PORTL*," an acronym for *Portable Operant Research and Teaching Laboratory* (Hunter & Rosales-Ruiz, 2018). Box 22.1 outlines the rationale for this exercise, and explains how to play PORTL with a partner for maximum benefit.[7]

With a Group

Keenan and Dillenburger (2000) described a classroom activity that teaches students shaping principles. Keenan and Dillenburger's "The Shaping Game," though sharing an identical name with Shimoff and Catania's (1995) computer simulation, is an *in vivo* experience shared by a group and it has a number of variations. The principal manner in which this game is played is to have a volunteer student initially exit the classroom temporarily while the remaining class members, guided by the instructor, reach consensus on the target behavior to shape when the volunteer re-enters the classroom. Target behaviors can be simple—walking to the front of the room and turning off a light switch—or be more elaborate movements (e.g., walking to the front of the room, standing on one foot while touching an elbow with the opposite hand). A volunteer "shaper" is also chosen.[8] Upon re-entry, the shaper clicks and then reinforces the first behavior that approximates the terminal behavior. Other behaviors or movements are placed on extinction. The Shaping Game concludes when the volunteer performs the terminal behavior targeted by the class. According to Keenan and Dillenburger the upshot of The Shaping Game is to:

1. Teach the basic principles involved in shaping.
2. Teach about the power of contingencies of reinforcement.
3. Demonstrate the operation of stimulus control.
4. Demonstrate the value and difficulty of continuously monitoring the behavior of a single organism.
5. Demonstrate how questionnaires produce an incomplete account of behavior (p. 22).

BOX 22.1

Learn Shaping by Playing PORTL

PORTL (Portable Operant Research and Teaching Lab) is a second-generation table-top shaping game, originally developed by canine trainer Kay Laurence and now extrapolated to human participants by Jose Rosales-Ruiz and his graduate students at the University of North Texas.

Rationale for Playing PORTL

PORTL teaches participants to shape behavior entirely through delivering reinforcement and changing environmental arrangements. Early training exercises help individuals practice shaping basics—observing behavior, clicking a clicker at the next successive approximation movement of their partner, reinforcing simple behaviors consistently, and collecting and recording data collection—without the benefit of verbal instructions, models, gestures, or prompts. During intermediate training, individuals continue to learn additional concepts, including cueing and stimulus control, concept formation, chaining, schedules of reinforcement, superstitious behavior, extinction, and resurgence, to name a few. Ultimately, individuals gain experiences being the teacher *and* the learner, which helps to build understanding and empathy as the learner relates to the challenges the game presents to his or her students.

How Is PORTL Played?

PORTL is played between two individuals, the teacher and the learner, using a collection of small objects, a clicker to "mark" behavior, and small tokens or blocks as reinforcers.

At the beginning of each exercise, the teacher presents the learner with a selection of objects. The learner is given only two instructions: "Your goal is to earn as many blocks as possible" and "Please interact with the objects."

When the learner performs the correct behavior or an approximation toward the correct behavior, the teacher clicks the clicker and delivers a contingent token. The learner places the token into a container and then resumes interacting with the objects. The teacher can rearrange the objects or add and remove objects to help guide the learner toward the goal behavior.

The teacher and learner take breaks periodically to fill out datasheets. The teacher records what just happened and what she plans to teach during the next training period. The learner records what he thinks he is learning and his perception of the exercise. Breaks can be taken after a criterion number of tokens have been delivered (e.g., 10 tokens) or after a certain amount of time (e.g., 60 seconds). Breaks allow the teacher to continually assess the learner's progress and to adjust the shaping plan.

After each exercise, the teacher and learner compare datasheets. In addition, the learner can provide valuable feedback about what the teacher did well, as well as insight regarding which parts of the exercise may have been confusing and why.

SUMMARY

Shaping Defined

1. Shaping consists of a three-part process whereby the analyst (a) detects a change in the learner's environment, (b) makes a discriminated judgment about whether that change is a progressively closer approximation to a terminal behavior of interest, and then (c) differentially reinforces that closer successive approximation. Shaping is defined as the differential reinforcement of successive approximations toward a terminal behavior.

2. A terminal behavior—the end product of shaping—can be claimed when the topography, rate, latency, duration, interresponse time, or magnitude of the target behavior reaches a predetermined criterion level.

3. Differential reinforcement refers to the act of presenting an unconditioned or conditioned reinforcer only to those emitted members of a response class that share a specified dimension or quality, while placing all other emitted response class members on extinction.

4. Differential reinforcement has three effects: Responses similar to those that have been reinforced are more likely to occur, responses resembling the unreinforced members are emitted less frequently (i.e., undergo extinction), and some of these emitted responses under extinction may be likely to resemble the next successive approximation to the terminal behavior and would therefore be targeted for reinforcement.

5. When differential reinforcement is applied consistently within a response class, its triple effect results in a new response class composed primarily of responses sharing the characteristics of the previously reinforced subclass. This emergence of a new response class is called response differentiation.

6. The gradually changing criterion for reinforcement during shaping results in a succession of new response classes, or successive approximations, each one closer in form to the terminal behavior than the response class it replaces.

7. Behavior can be shaped along measurable dimensions of topography (form), rate (number of responses per unit of time), latency (time between the onset of the antecedent stimulus and the occurrence of the behavior), duration (elapsed time from the onset of a response to its end point), interresponse time (time between responses), and magnitude (response strength or force).

Shaping Across and Within Response Topographies

8. Shaping behavior across different response topographies means that selected members of a response class are differentially reinforced, whereas members of other response classes are placed on extinction.
9. Shaping a behavior within a response topography means that the form of the behavior remains constant, but differential reinforcement is applied to another measurable dimension of the behavior (e.g., magnitude).
10. Shaping is a positive approach to teach new behavior and may be combined with other behavior change tactics.
11. Shaping has at least five limitations that practitioners should consider before applying it.
12. In shaping, the antecedent stimulus stays the same, while the response progressively becomes more differentiated. In stimulus fading, the response remains the same, while the antecedent stimulus changes gradually.

Increasing Shaping Efficiency

13. Shaping may become more efficient by using a discriminative stimulus, physical guidance, imitative prompts, and/or a percentile schedule. Any prompt that is introduced should be faded later.

Clicker Training

14. Clicker training is a science-based system for progressively shaping behavior using positive reinforcement and extinction.
15. The clicker, a handheld device that produces a clicking sound when a metal tab is pressed, provides the signal that when a behavior is being performed in the presence of the click, reinforcement follows.

Emerging Applications of Shaping

16. Using computers to teach shaping, combining shaping procedures with robotics engineering, and applying telemedicine technology for humanitarian purposes for populations in hard-to-access settings serve as three emerging applications of shaping.

Shaping Guidelines

17. Before deciding to use shaping, assess the nature of the behaviors to be learned, the staff requirements and resources available, and whether a different tactic altogether might be more efficient in terms of time and effort.
18. After the decision has been made to use a shaping procedure, the practitioner performs the following steps: select the terminal behavior, decide the criterion for success, analyze the response class, identify the first behavior to reinforce, eliminate interfering or extraneous stimuli, proceed gradually, limit the number of approximations at each level, continue reinforcement when the terminal behavior is achieved, and learn to shape behavior.

Learning to Shape

19. To learn to shape behavior, consider shaping a simple behavior, working with a colleague, practicing with a group, or using a computer-based simulator.

KEY TERMS

clicker training
differential reinforcement
extinction-induced variability
response differentiation
shaping
successive approximation

MULTIPLE-CHOICE QUESTIONS

1. Shaping involves:
   a. Reinforcing successive approximations to a terminal behavior
   b. Creating response differentiation between responses that are closer to the terminal behavior and those that are not
   c. Placing responses that are not a closer approximation of the terminal behavior on extinction
   d. All of these

   Hint: (See "Shaping defined")
2. Which of the following is an example of shaping an individual to swing a golf club correctly (i.e., take the appropriate backswing, swing the club down to the ball, and follow through with the swing)?
   a. Stand behind the person and physically help make the correct golf swing. Over time, slowly provide less physical assistance until the individual makes a correct swing independently.
   b. Start with verbal prompts to do each step. If this is not effective, provide a model. If this is not effective,

provide some physical assistance. If this is not effective, stand behind the person and help the person make the correct golf swing.

c. Provide positive reinforcement for any swing that resembles a golf swing. Then, provide reinforcement for closer and closer approximations of a correct golf swing and withhold reinforcement for poorer approximations of a correct golf swing.

d. None of these is an example of shaping.

Hint: (See "Shaping defined")

3. Response differentiation involves what two components?

a. Differential reinforcement and changing the criterion for reinforcement

b. Punishment and extinction

c. Prompting and differential reinforcement

d. Extinction and changing the criterion for reinforcement

Hint: (See "Shaping defined")

4. Ms. Anita Response wants to increase the number of words Sophie writes in her stories during creative writing time. She uses shaping to do so. What dimension of behavior is she shaping?

a. Amplitude

b. Frequency

c. Duration

d. Latency

Hint: (See "Shaping defined")

5. An example of shaping within a response topography is:

a. Increasing the number of math problems an individual needs to complete during math class

b. Increasing the duration of in-seat behavior during seatwork time

c. Increasing the force of a tennis swing

d. All of these are examples of shaping within a response topography

Hint: (See "Shaping across and within Response Topographies")

6. The text gives an example of shaping gum chewing, in which lip movement first received reinforcement, then lip movements with sound, then saying the word "gum," and finally, saying "Gum please." This is an example of:

a. Shaping within a response topography.

b. Shaping across different response topographies.

c. Shaping the magnitude of a response.

d. Shaping the duration of a response.

Hint: (See "Shaping across and within Response Topographies")

7. Shaping can be a slow, time-consuming process. What is one way to effectively speed up the process?

a. Add a punishment contingency for incorrect responses.

b. Each time you increase the criteria for reinforcement, do so by larger increments.

c. Model the desired response for the individual.

d. All of these are effective ways to make shaping more efficient.

Hint: (See "Increasing Shaping Efficiency")

8. When is adding a prompt to the shaping process something to consider?

a. When the individual is progressing through the shaping procedure quickly.

b. When the individual has mastered the terminal behavior.

c. When the individual's repertoire is weak and the likelihood of making a successive approximation is low.

d. When you have limited staff and resources to implement the shaping procedure.

Hint: (See "Increasing Shaping Efficiency")

9. What is meant by the statement that progress in shaping is rarely linear and often erratic?

a. Most individuals are unsuccessful in shaping new responses.

b. The amount of time it may take to shape a behavior is often unpredictable.

c. Sometimes individuals may exceed your criteria for reinforcement, making closer approximations than you had expected.

d. Sometimes individuals may get "stuck" on a response and have to "back up" to a previously-learned approximation before making process. This can slow the process down more than expected.

e. All of these

f. None of these

Hint: (See "Shaping Guidelines")

10. One of the guidelines for effective shaping is to carefully define the terminal behavior and the criteria for successfully engaging in the terminal behavior. Effective ways for deciding what are the criteria for success:

a. Read the research literature to see if there are published norms and guidelines available for the behavior you are trying to shape.

b. Observe competent peers to see how well they perform the task, and set your criteria according to their performance level.

c. Both of these are ways to determine the criteria for success.

d. Neither of these are appropriate ways to determine criteria for success.

Hint: (See "Shaping Guidelines")

ESSAY-TYPE QUESTIONS

1. Write the definition of shaping and provide an example of shaping that has not been discussed in class or presented in the textbook. When giving your example, analyze the response class and diagram the shaping process.

   Hint: (See "Shaping Defined")

2. What are the behavioral processes involved in the shaping process?

   Hint: (See "Shaping Defined")

3. What is the key difference between shaping across response topographies and shaping within a response topography?

   Hint: (See "Shaping across and within Different Response Topographies")

4. Shaping a new response can take a long time. What is one way you can increase the efficiency of shaping and speed up the process?

   Hint: (See "Increasing Shaping Efficiency")

5. What key steps are to be taken to implement the shaping process?

   Hint: (See "Shaping Guidelines")

NOTES

1. When applied to discrimination training, differential reinforcement requires (1) reinforcing responses in the presence of one stimulus condition (the S^D) and (2) placing responses in the absence of the S^D condition on extinction. Refer to Chapters 17 and 24 for this discussion.
2. Spirometers are not calibrated to show minute, incremental changes. They register units in larger whole numbers (500 ml, 1000 ml, etc.). The point remains that the therapist is actively (a) watching the spirometer to detect a change in breathing, (b) judging whether that change is a successive approximation higher than a previous attempt, and (c) reinforcing it if it is. Simultaneously, attempts that do not approximate the terminal behavior are placed on extinction.
3. Procedures for chaining a sequence of responses to a terminal outcome are described in Chapter 23.
4. The researcher provided a safety net so that the rat was not injured.
5. They also developed simulations for reinforcement schedules.
6. An American-size football field, end-zone-to-end-zone and sideline-to-sideline, is approximately 1.32 acres.
7. Accessing https://youtu.be/YSu7ghj4ib0 shows a video clip of PORTL being conducted.
8. Some variations have the entire class serve as the shaper by having them clap collectively when an approximation occurs.

CHAPTER 23

Chaining

LEARNING OBJECTIVES

- Define and give examples of behavior chains.
- Identify why behavior chains are important.
- Conduct a task analysis and select appropriate assessment methods for evaluating performance on task analysis.
- Identify and define different chaining procedures and determine when each would be selected for use.
- Describe how behavior chains can be interrupted.

At age 21, I was a newly employed counselor at a summer camp designed to provide educational, social, and recreational experiences to children with cerebral palsy. One of the campers—let's call him "Joe"—wore flapjack shoes that featured a mechanical upper tongue that clamped down to secure the shoes to his feet. I soon learned that Joe wore the flapjacks not as a fashion statement, but because he hadn't learned to tie his own shoelaces. A senior counselor challenged me to teach Joe to tie his shoes before the camp ended in approximately two weeks. I happily accepted the challenge, as an authentic Philadelphia cheesesteak sandwich hung in the balance.

I launched this project with my "go to" procedure—backward chaining. I used a practice jig that consisted of canvas cloth with holes at each border wrapped around a wooden board. I tied the laces completely, but loosely, and then held the jig out to Joe and said, "Tie your shoe." Joe snugged the laces tight, the last behavior in the chain. I reset the jig to my initial position, and repeated my direction to Joe, "Tie your shoe." Once Joe mastered the snugging task, the second behavior to teach was the next-to-the-last task in the shoe-tying sequence: drawing the looped laces down to the wooden template (before snugging them tight as before). And so the process continued until the first task in the sequence (i.e., crossing the laces) was completed. Each time Joe completed the chain, from performing the final step only in his very first trial to completing each step in sequence from the beginning, he contacted the natural reinforcer (a self-tied shoe) and social praise ("Good job, Joe!").

Practice occurred for about 10 to 15 minutes per day, three days per week. In the remaining days of the camp, Joe practiced the entire chain a few times with an Oxford-style shoe. However, on the last day of the camp, and sporting a new pair of sneakers, the senior counselor asked Joe to tie his shoe. Joe responded with the precision of a Swiss watchmaker. I reveled in Joe's success and enjoyed a delightful lunch to boot! Backward chaining chalked up another victory.

—Tim Heron

This chapter defines a behavior chain, provides a rationale for establishing behavior chains in applied settings, and discusses the importance of task analysis in behavior chain training. The chapter presents a procedures for constructing and validating task analyses, along with procedures for assessing individual mastery levels. Next, four behavior change methods—forward chaining, total-task chaining, backward chaining, and backward chaining with leap aheads—are addressed, followed by guidelines for deciding which behavior chain procedure to use in applied settings. Techniques for interrupting and breaking inappropriate chains are also provided. The chapter concludes with an examination of factors affecting the performance of a behavior chain.

BEHAVIOR CHAIN DEFINED

A **behavior chain** is a linked sequence of responses leading to a terminal outcome. Each response produces a stimulus change that functions as conditioned reinforcement for that response and as a discriminative stimulus (S^D) for the next response in the chain. Reinforcement for the last response in a chain maintains the reinforcing effectiveness of the stimulus changes produced by all previous responses in the chain.

Reynolds (1975) provided this laboratory example of a behavior chain (illustrated in Figure 23.1):

> Assume that a pigeon is presented with a blue light key (S_1). When the pigeon pecks the key (R_1), the blue light terminates, and a red light is activated. In the presence of the red light key (S_2), the pigeon presses a pedal (R_2) that turns the key to a yellow light. The yellow light (S_3) serves as an S^D to displace a bar (R_3), which terminates the yellow light, changing it to a green light (S_4). Finally, during the green light (S_4), pecks terminate the green light, and a grain-delivery mechanism is activated that dispenses an edible reinforcer. . . . Because each stimulus has a dual function, as discriminative stimulus and conditioner reinforcer, the links overlap. In fact, it is this dual function of the stimuli that holds the chain together. (pp. 59–60)

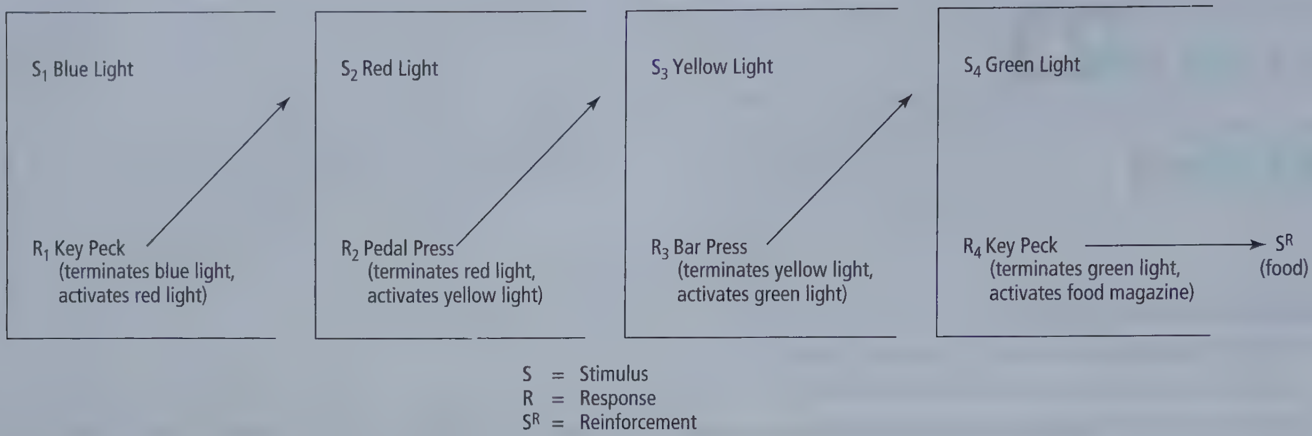

Figure 23.1 Illustration of a behavior chain consisting of four components.
Based on a chain described by Reynolds (1975, pp. 59–60).

As Figure 23.1 shows, this chain includes four responses (R_1, R_2, R_3, and R_4), with a specific stimulus condition (S_1, S_2, S_3, and S_4) associated with each response. The blue light (S_1) is an S^D to occasion the first response (R_1), a key peck that terminates the blue light and produces the onset of the red light (S_2). The red light serves as conditioned reinforcement for R_1 and as an S^D for R_2 (a pedal press). The pedal press (R_2) terminates the red light and produces the onset of the yellow light (S_3), and so on. The last response produces food, thus completing and maintaining the chain.

Figure 23.2 shows the links of a behavior chain using a classroom example. In preparing a class of preschool students for recess, the teacher might say to one student, "Please put on your coat." The teacher's statement would serve as the S^D (S_1) evoking the first response (R_1) in the chain, securing the coat in hand from the closet. That response in the presence of the teacher's statement terminates the teacher's statement and produces the onset of the coat in the student's hands (S_2). The coat in the student's hands serves as conditioned reinforcement for obtaining the coat from the closet (R_1) and as an S^D (S_2) for putting one arm through a sleeve (R_2). That response, putting one arm through the sleeve in the presence of the coat in both hands, terminates the stimulus condition of the coat in the student's hands and produces the onset of one arm in a sleeve and one arm out (S_3), a stimulus change that serves as conditioned reinforcement for putting one arm through a sleeve and as an S^D (S_3) for placing the second arm through the other sleeve (R_3). That response terminates the condition of one arm in a sleeve and one arm out, and produces the S^D (S_4) of the coat being completely on. The coat being fully on serves as a conditioned reinforcer for putting the second arm through the other sleeve and as an S^D for zipping it (R_4). Finally, zipping up the coat completes the chain and produces teacher praise, and the natural consequence of wearing a fully zipped coat.

A behavior chain has three important characteristics: (a) It involves the performance of a specific series of discrete responses; (b) the performance of each behavior in the sequence produces a stimulus change in the environment in such a way that it yields conditioned reinforcement for the preceding response, and serves as an S^D for the next response; and (c) the responses within the chain must be performed in a specific sequence, and in close temporal succession.

Behavior Chains with a Limited Hold

A **behavior chain with a limited hold** is a chain that must be completed within a specified time to produce reinforcement. Behavior chains with limited holds are characterized by performance that is accurate *and* proficient. An assembly task on a production line exemplifies a chain with a limited hold. Suppose that to meet the production requirements of the job, an employee has to assemble 30 couplers onto 30 shafts within 30 minutes (one per minute). If the coupler is placed on the shaft, the retaining clip applied, and the unit forwarded to the next person in line within the prescribed period, reinforcement is delivered. In a behavior chain with a limited hold, the person must not only have the prerequisite behaviors in his repertoire, but also must emit those behaviors in close temporal succession to obtain reinforcement.

Figure 23.2 Discriminative stimuli, responses, and conditioned reinforcers in a four-response chain.

Discriminative Stimulus	Response	Conditioned Reinforcement
S_1 "Put on your coat."	R_1 Obtain coat from closet	Coat in hands
S_2 Coat in hands	R_2 Place one arm in sleeve	One arm in sleeve
S_3 One arm in sleeve/one arm out	R_3 Place second arm in sleeve	Coat on
S_4 Coat on	R_4 Zip up the coat	Teacher praise

When working with a client who completes a chain in the correct sequence, but fails to meet the limited hold criterion, the behavior analyst should measure the latency and duration of each component response. If this assessment reveals that the client is taking too much time to complete one or more component responses, the behavior analyst can implement contingencies focusing on the proficiency of performance. Setting a time criterion for the onset and completion of each response within the chain is one way to do this; another is to set a time criterion for completion of the total chain.

RATIONALE FOR CHAINING

Whereas *behavior chain* denotes a particular sequence of stimuli and responses ending in reinforcement, **chaining** refers to various methods for linking specific sequences of stimuli and responses to form new performances. In forward chaining, behaviors are linked beginning with the *first* behavior in the sequence. In backward chaining, the behaviors are linked beginning with the *last* behavior in the sequence (Murphy & Lupfer, 2011). Both of these procedures and their variations are discussed in detail later in this chapter.

New behavior chains are taught to people for several reasons. First, an important educational aspect of programs for students with development disabilities—and, for that matter, novice learners—is to increase independent-living skills (e.g., using public utilities, taking care of personal needs, executing travel skills, socializing appropriately). As these skills develop, the learner functions more effectively in least restrictive environments or participates in activities without adult supervision. Complex behaviors that are developed with chaining procedures allow individuals to function more independently.

Second, chaining provides the means by which a series of discrete behaviors can be combined to form a sequence of responses that occasion the delivery of reinforcement. That is, chaining can be used to add behaviors to an existing behavioral repertoire. For example, assume that a person with a developmental disability consistently seeks assistance from a coworker or job coach while completing an assembly task. A chaining procedure could be used to increase the number of tasks in the assembly that must be performed before reinforcement is delivered. To do so, the teacher could give the individual a written or pictorial list of the parts that must be assembled to complete the job. When the first task is finished, the worker crosses off the first word or picture on the list and then proceeds to the next task.

In behavioral terms, the first word or picture on the list serves as the S^D to occasion the response of completing the first task. That response, in the presence of the word or picture on the list, terminates the initial stimulus and produces the next stimulus, the second word or picture on the list. The completion of the second task serves as conditioned reinforcement for completing the task and produces the onset of the third S^D. In this way, the chaining procedure enables simple behaviors to be combined into a longer series of complex responses.

Finally, chaining can be combined with other behavior change tactics to build more intricate and adaptive repertoires. McWilliams, Nietupski, and Hamre-Nietupski (1990) taught three students with moderate intellectual disabilities a 24-step chain of bedmaking skills with an intervention that combined chaining with modeling and error correction. Lambert and colleagues (2016) used a forward chaining procedure that incorporated prompting, instructions, and modeling to teach three complex chains of basketball skills to a middle school student with autism.

ESTABLISHING BEHAVIOR CHAINS WITH TASK ANALYSIS

Before individual behaviors can be linked in a chain, the behavior analyst must construct and validate a task analysis of the components of the behavioral sequence, and assess the learner's mastery level of each behavior in the task analysis. **Task analysis** involves breaking a complex task into smaller, teachable units, the product of which is a series of sequentially ordered steps or tasks.

Constructing and Validating a Task Analysis

The purpose of constructing and validating a task analysis is to determine the sequence of behaviors that are necessary and sufficient to complete a given task efficiently. The sequence of behaviors that one person performs may not be identical to what another person needs to achieve the same outcome. A task analysis should be individualized according to the age, skill level, and prior experience of the learner (Brown, McDonnell, & Snell, 2016). Further, a few task analyses comprise a limited number of major steps, with each major step containing four to five subtasks. Figure 23.3 illustrates a task analysis for making a bed, developed by McWilliams and colleagues (1990).

Researchers and practitioners typically construct and validate task analyses using one method or a combination of four methods: observe a competent performer, execute the task yourself, ask an expert, or trial and error.

Observe a Competent Performer

Test, Spooner, Keul, and Grossi (1990) produced a task analysis for using a public telephone by observing two adults perform the task, and then validating that sequence by training a person with developmental disabilities to use the task analysis. Based on the training, the researchers made subsequent modifications to the original sequence of tasks.

Execute the Task Yourself

A study by van den Pol and colleagues (1981) serves as a good example of how to determine and validate a task analysis yourself. To identify the behaviors required to eat in fast-food restaurants, their research team ate in a variety of restaurants and self-recorded their activities. The researchers next combined their individual findings into a 22-item task analysis that covered differences among restaurants and then organized the steps into four skills clusters: locating, ordering, paying and eating, and exiting (see Figure 30.1). The advantage of self-performing the task is threefold: (1) It provides the opportunity to come into contact with all task demands of the sequence, (2) it generates a clearer idea of the behaviors to be taught and their associated S^Ds, and (3) it refines the description of the response topography necessary for the learner

Figure 23.3 Task analysis of bedmaking skills.

Given an unmade bed that included a messed-up bedspread, blanket, pillow, and flat sheet and a fitted sheet, the student will:

Section 1: bed preparation
1. remove pillow from bed
2. pull bedspread to foot of bed
3. pull blanket to foot of bed
4. pull flat sheet to foot of bed
5. smooth wrinkles of fitted sheet

Section 2: flat sheet
6. pull top of flat sheet to headboard
7. straighten right corner of flat sheet at foot of bed
8. repeat #7 for the left corner
9. make sheet even across top end of mattress
10. smooth wrinkles

Section 3: blanket
11. pull top of blanket to headboard
12. straighten right corner of blanket at foot of bed
13. repeat #12 for the left corner
14. make blanket even with sheet across top end of mattress
15. smooth wrinkles

Section 4: bedspread
16. pull top bedspread to headboard
17. pull right corner of bedspread at foot to floor
18. repeat #17 for left side
19. make bedspread even with floor on both sides
20. smooth wrinkles

Section 5: pillow
21. fold top of spread to within 4 inches of the pillow width
22. place pillow on folded portion
23. cover pillow with the folded portion
24. smooth bedspread wrinkles on and around the pillow

From "Teaching Complex Activities to Students with Moderate Handicaps Through the Forward Chaining of Shorter Total Cycle Response Sequences," by R. McWilliams, J. Nietupski, & S. Hamre-Nietupski, 1990, *Education and Training in Mental Retardation, 25,* p. 296.

to use the sequence most efficiently. Figure 23.4 shows how an initial 7-step sequence for tying a shoe was expanded to 14 steps after self-performing the behavior (cf. Bailey & Wolery, 1992).

Expert Input

Persons or associations with recognized and demonstrated expertise can be a valuable resource to consult when validating a task analysis. For example, Stokes, Luiselli, and Reed (2010) based a 10-step task analysis for football tackling skills on recommendations by the *American Football Coaches Association* (1995). Stokes, Luiselli, Reed, and Fleming (2010) asked five college offensive line coaches to validate a 10-step task analysis for pass-blocking by offensive linemen (see Figure 23.5).

Trial and Error

A systematic trial-and-error procedure can assist the behavior analyst in developing a task analysis. Using a systematic trial-and-error method, an initial task analysis is generated and then refined and revised as it is being tested. With revisions and refinements obtained through field tests, a more functional and appropriate task analysis can be achieved. For instance, as mentioned earlier, Test and colleagues (1990) generated their initial task analysis for using a public telephone by watching two adults complete the task. They subsequently carried the process a step further by asking a person with developmental disabilities to perform the same task and then modified the task analysis.

Regardless of the method used to sequence the steps, the S^Ds and corresponding responses must be identified. However, being able to perform a response is not sufficient; the individual must be able to discriminate the conditions under which a given response should be performed. Listing the discriminative stimuli and associated responses helps the trainer determine whether naturally occurring S^Ds will evoke different or multiple responses.

Assessing Mastery Level

Mastery level is assessed to determine which components of the task analysis the learner can perform independently.

Figure 23.4 Initial and expanded steps for teaching shoe tying.

Shorter sequence[a]	Longer sequence[b]
1. Partially tighten shoe laces.	8. Pinch lace.
2. Pull shoe laces tight—vertical pull.	9. Pull lace.
3. Cross shoe laces.	10. Hang lace ends from corresponding sides of shoe.
4. Tighten laces—horizontal pull.	11. Pick up laces in corresponding hands.
5. Tie laces into a knot.	12. Lift laces above shoe.
6. Make a bow.	13. Cross right lace over the left to form a tepee.
7. Tighten bow.	14. Bring left lace towards student.
	15. Pull left lace through tepee.
	16. Pull laces away from each other.
	17. Bend left lace to form a loop.
	18. Pinch loop with left hand.
	19. Bring right lace over the fingers—around loop.
	20. Push right lace through hole.
	21. Pull loops away from each other.

Figure 23.5 Task analysis for pass-blocking by offensive linemen.

Step		Description
1	Stance	Feet shoulder-width apart, 50% bend at the knees, buttocks down over heels, center-side hand touching the ground
2	Split	Sideline foot back slightly with toe to heel of center-side foot
3	First step	Make play-side bucket step while maintaining balance
4	Helmet contact	Helmet facemask makes contact with opponent at the top of jersey number
5	Hand placement	Pointer fingers at 11:00 o'clock and 1:00 o'clock with thumbs pointed towards opponent's Adam's apple
6	Hand position	Hands maintained inside opponent's shoulder pads and torso frame
7	Arm extension	Arms extended outward beyond 45 degrees
8	Hip follow through	Hips rolled towards opponent's belly button
9	Leg drive	Maintain continuous running leg pump until whistle sounds
10	Hand contact	Hands in contact with opponent's body until whistle sounds

There are two principal ways to assess a person's mastery level of task analysis behaviors prior to training—the single-opportunity method and the multiple-opportunity method.

Single-Opportunity Method

The single-opportunity method is designed to assess a learner's ability to perform each behavior in the task analysis in correct sequence. Lambert and colleagues (2016) used a single-opportunity method to assess target chains related to teaching functional basketball skills to an adolescent with autism. If a behavior in the chain was emitted correctly, confederate players on the court repositioned themselves so as to serve as the S^D for the next behavior. If that behavior was not performed, the assessment probe terminated.

Figure 23.6 is an example of a form used to record a learner's ability to insert a hearing aid. Specifically, a plus sign (+) or minus sign (−) is marked for each behavior that is correctly or incorrectly emitted.

Assessment in this example began when the teacher said, "Tom, put on your hearing aid." Tom's responses to the steps in the task analysis were then recorded. The figure shows Tom's data for the first 4 days of assessment. On Day 1, Tom opened the hearing aid container and removed the harness; each of these steps was performed correctly, independently, sequentially, and within a 6-sec time limit. However, Tom then attempted to put the hearing aid harness over his head (Step 5) without first doing Steps 3 and 4. Because he continued to perform this behavior for more than 10 seconds, the teacher stopped the assessment and scored Steps 3 and 4 and all remaining steps as incorrect. On Day 2, Tom was stopped after Step 1 because he performed a subsequent step out of order. On Days 3 and 4, the assessment was discontinued after Step 4 because Tom took more than 6 seconds to perform Step 5. Given a criterion for mastery of 100% accuracy within 6 seconds over three consecutive probes, the data indicate that Tom only met the criterion for Step 1 (the three +'s for Step 2 were not recorded consecutively).

Multiple-Opportunity Method

The multiple-opportunity method of task analysis assessment evaluates the learner's level of mastery across all the behaviors in the task analysis. If a step is performed incorrectly or out of sequence, or if the time limit for completing the step is exceeded, the behavior analyst completes that step for the learner and then positions her for the next step. Each step performed correctly is scored as a correct response, even if the learner erred on the previous steps.

Figure 23.7 shows an example of the multiple-opportunity method for assessing a student's (Marc's) morning-arrival routine across 17 tasks and 10 days. Brown et al. (2016) validated their task analysis by (a) watching other students complete the morning-arrival routine, (b) conferring with Marc's teacher to

gain her perspective on the tasks, and then (c) "piloting" the task analysis with Marc to ensure that it was individualized. After accomplishing these three validation procedures, it was noted that a couple of tasks were still too difficult for Marc, so each of those steps was further subdivided into two steps. Brown et al. recommend that practitioners developing a task analysis use a systematic process to do so (see Box 23.1).

The key to using the multiple-opportunity method for a task analysis assessment is to ensure that teaching is not commingled with assessment. That is, if the learner is unable to perform a task, the behavior analyst would complete that step, position the learner for the next step, and continue with remaining steps.

Single-opportunity and multiple-opportunity methods can be effective ways to determine mastery of initial skills in a behavior chain. Of the two, the single-opportunity method is the more conservative measure because the assessment terminates at the first step at which performance breaks down. It also provides less information to the teacher once instruction is initiated; but takes less time to conduct, especially if the task analysis is long, and it reduces the likelihood of learning taking place during assessment (Brown et al., 2016). The multiple-opportunity method takes more time to complete, but it provides the behavior analyst with more information. That is, the teacher could learn which steps in the task analysis the learner has already mastered, thus eliminating the need to instruct steps already in the learner's repertoire. In the next section, we address the third component of chaining: teaching the individual to perform each step of the chain in close temporal succession.

BEHAVIOR CHAINING METHODS

After the task analysis has been constructed and validated and the criterion for success and the data collection procedures have been determined, the next step is to decide which chaining procedure to use in teaching the new sequence of behaviors. The behavior analyst has four options: forward chaining, total-task chaining, backward chaining, and backward chaining with leap aheads.

Forward Chaining

In **forward chaining**, the behaviors identified in the task analysis are taught in their naturally occurring order. Specifically, reinforcement is delivered when the predetermined criterion for the performance of the first behavior in the sequence is achieved.

BOX 23.1

How the Task Analysis for Marc's Morning Routine Was Developed

Analyzing a chain of events and breaking these tasks down into teachable steps is not a trivial process. Consider how Marc's teachers developed his task analysis and the data collection form for his morning routine (Figure 23.7). Ms. Wharton, the special education teacher, and the school's autism specialist watched other children perform the morning routine tasks and then analyzed the steps. They identified the relevant stimuli Marc needed to attend to and the responses they wanted Marc to learn. Ms. Wharton also asked Marc's kindergarten teacher, Ms. Kwan, to double-check the preliminary task analysis steps by using them when observing other students arrive in the morning. Ms. Wharton then piloted the task analysis with Marc to be sure the steps made sense for him. When she found that some of the steps were too hard for Marc to do alone (e.g., Step 2: Open the door of the building), she modified those steps by either breaking that step into two smaller steps or adding adult/peer assistance. Marc's mother, who was familiar with the arrival routine, then reviewed the task analysis and added her own ideas. The speech-language pathologist suggested adding a greeting. The 17-step task analysis for Marc's arrival routine reflects the cumulative input of the teachers, the speech therapist, and Marc's mother, thus significantly enhancing the validation process.

Teams will develop more successful task analyses if they follow a systematic process:

1. Select a needed skill by using ecological inventory results to identify a functional and age-appropriate skill that is an important target for a particular student.
2. Define the target skill simply, including a description of the settings and materials most suited to the natural performance of the task.
3. Perform the task and observe peers performing the task, using the chosen materials in the natural settings while noting the steps involved.
4. Adapt the steps to suit the student's disabilities and skill strengths; employ as needed the principle of partial participation, the only-as-specialized-as-necessary rule, and component analysis to design a task analysis that is both age appropriate and functional.
5. Validate the task analysis by having the student perform the task, but provide assistance on steps that are unknown so that performance of all of the steps can be viewed.
6. Revise the task analysis so that it works; explore adding simple, non-stigmatizing adaptations to steps that appear to be unreasonable in an unadapted form.
7. Write the task analysis on a data collection form so that steps (a) are stated in terms of observable behavior; (b) result in a visible change in the product or process; (c) are ordered in a logical sequence; (d) are written in second-person singular so that they could serve as verbal prompts (if used); and (e) use language that is not confusing to the student, with the performance details that are essential to assessing enclosed in parentheses.

Adapted from *Instruction of Students with Severe Disabilities* (8th ed.), pp. 158–159, by F. E. Brown, J. J. McDonnell, and M. E. Snell, 2016.

Thereafter, reinforcement is delivered for criterion completion of Steps 1 and 2. Each succeeding step requires the cumulative performance of all previous steps in the correct order.

For example, when the first step, "Pinch lace," is performed accurately 3 consecutive times, reinforcement is delivered (refer to Figure 23.4). Next, reinforcement would be delivered when that step and the next one, "Pull lace," are performed to the same criterion. Then, "Hang lace ends from corresponding sides of shoe" would be added, and all three steps would have to be performed correctly before reinforcement is delivered. Ultimately, all 14 steps in the task analysis should be performed in a similar manner. However, at any given training step a variety of response prompting and other strategies may be used to occasion the response.

Longer chains of behaviors can be broken down into smaller chains, or skill clusters, each of which can be taught in a manner similar to that used with a single-response unit. When one skill cluster is mastered, it is linked to the next. The final response in the first skill cluster sets the occasion for the first response in the second skill cluster. Essentially, in this variation skill clusters become the analogue for units of behaviors, and these clusters are linked.

McWilliams and colleagues (1990) combined skill clusters in forward chaining to teach bedmaking skills to three students with developmental disabilities. Based on a task analysis of bedmaking responses, five skill clusters were identified, each containing four to five subtasks (see Figure 23.3). Once baseline was collected showing minimal accuracy with completing the entire chain in the presence of the cue, "Show me how to make the bed," an instructional procedure was chosen that involved teaching the clusters one at a time by breaking the complex behaviors into smaller chains (see Figure 23.8).

Initial training began with the teacher demonstrating the chain of tasks for Sections 1 and 2. Subsequent training involved teaching the prior section, the current section targeted for instruction, and the next section in the sequence. For example, if training was to be conducted on Section 2, Sections 1, 2, and 3 were demonstrated. Next, the students practiced the targeted sequences 2 to 5 times. When the sequence was performed correctly, praise was delivered. When an error occurred, a three-part correction procedure involving verbal redirection, redirection plus modeling, and/or physical guidance was initiated until the trial ended on a correct response. When the first skill cluster was mastered (S_1), the second skill cluster (S_2) was introduced, followed by the third (S_3), the fourth (S_4), and so on.

The results indicated that the forward chaining procedure was effective in teaching the students bedmaking skills. That is, all the students were able to make their beds independently, or with only minimal assistance, when the teacher directed them to do so. Furthermore, all of them were able to make their beds in the generalization setting (i.e., the home).

McWilliams and colleagues (1990) and Guercio and Cormier (2015) illustrate three main advantages of forward chaining: (a) It can be used to link smaller chains into larger ones; (b) it is easy, so teacher implementation in the classroom is enhanced; and (c) it can be combined with other behavior change procedures (e.g., fading).

Despite its advantages, forward chaining has potential limitations. For example, it is possible that the analyst, after noting the learner has performed the targeted training steps, may

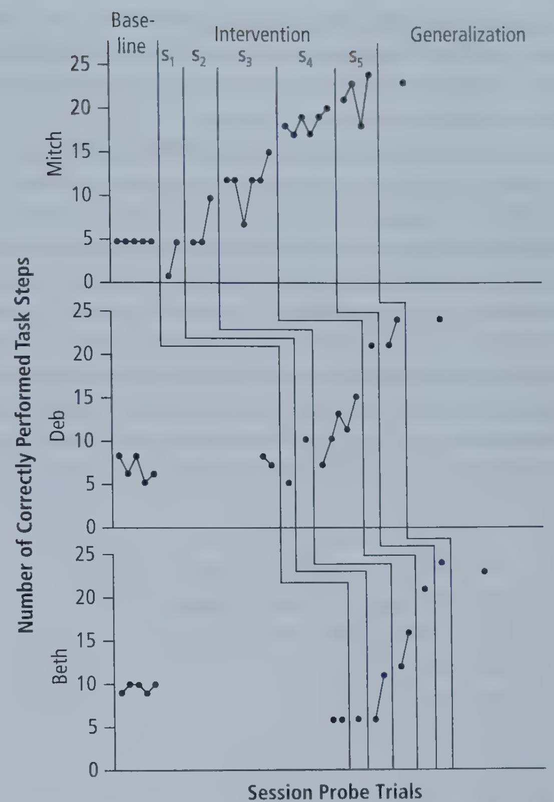

Figure 23.8 Number of correctly performed task steps across baseline, intervention, and generalization probe trials.

From "Teaching Complex Activities to Students with Moderate Handicaps Through the Forward Chaining of Shorter Total Cycle Response Sequences," by R. McWilliams, J. Nietupski, & S. Hamre-Nietupski, 1990, *Education and Training in Mental Retardation*, *25*, p. 296. Copyright 1990 by the Council for Exceptional Children. Reprinted by permission.

eliminate opportunities for additional practice of these steps, thus risking extinction of the chain due to lack of reinforcement or the weakening of an S^D. Conversely, the analyst may retain the learner in forward chaining intervention longer than necessary, thereby hampering progress on additional skills to be learned. To mitigate either or both of these limitations, Lambert et al. (2016) suggest that analysts probe the entire chain periodically to assess mastery and retention.

Our discussion thus far has focused on teaching behavior chains through direct teacher instruction. However, evidence suggests that chained responses can also be learned through observation (Wolery, Ault, Gast, Doyle, & Griffen, 1991). Griffen, Wolery, and Schuster (1992) used a constant time delay (CTD) procedure to teach students with intellectual disabilities a series of chained tasks in food preparation behaviors. During CTD with one student to whom the chained response was taught, two other students watched. Results showed that the two observing students learned at least 85% of the correct steps in the chain even though direct instruction on those steps had not occurred.

Total-Task Chaining

Total-task chaining (sometimes called *total-task presentation* or *whole-task presentation*) is a variation of forward chaining in which the learner receives training on each step in the task analysis during

every session. The trainer provides assistance for any steps the learner is unable to perform independently, and the chain is trained until the learner is able to perform all the behaviors in the sequence to the predetermined criterion. Depending on the complexity of the chain, the learner's repertoire, and available resources, physical assistance and/or graduated guidance may be incorporated.

Werts, Caldwell, and Wolery (1996) used peer models and total-task chaining to teach skills such as operating an audiotape, sharpening a pencil, and using a calculator to three elementary-level students with disabilities who were enrolled in general education classrooms. Response chains were individualized for each student based on teacher-recommended sequences that the students had to learn. Each session was divided into three parts: (a) The students with disabilities were probed on their ability to perform the total-task response chain; (b) a competent peer model demonstrated the chain in its entirety while simultaneously describing each step; and (c) the student partner was probed again to determine performance of the chain. During the probes before and after peer modeling, the students with disabilities were directed to complete the chain. If a student was successful, a correct response was noted, but no feedback was delivered. If a student was unsuccessful, the student's view was blocked temporarily while the teacher completed that step in the chain, and then the student was redirected to complete the remaining steps. Each behavior in the response chain was scored.

All three students learned to complete the response chain after peer modeling, and reached criterion on the response chain (100% correct for 2 out of 3 days) over the course of the study. The results for Charlie, one of the three students in the study, are shown in Figure 23.9.

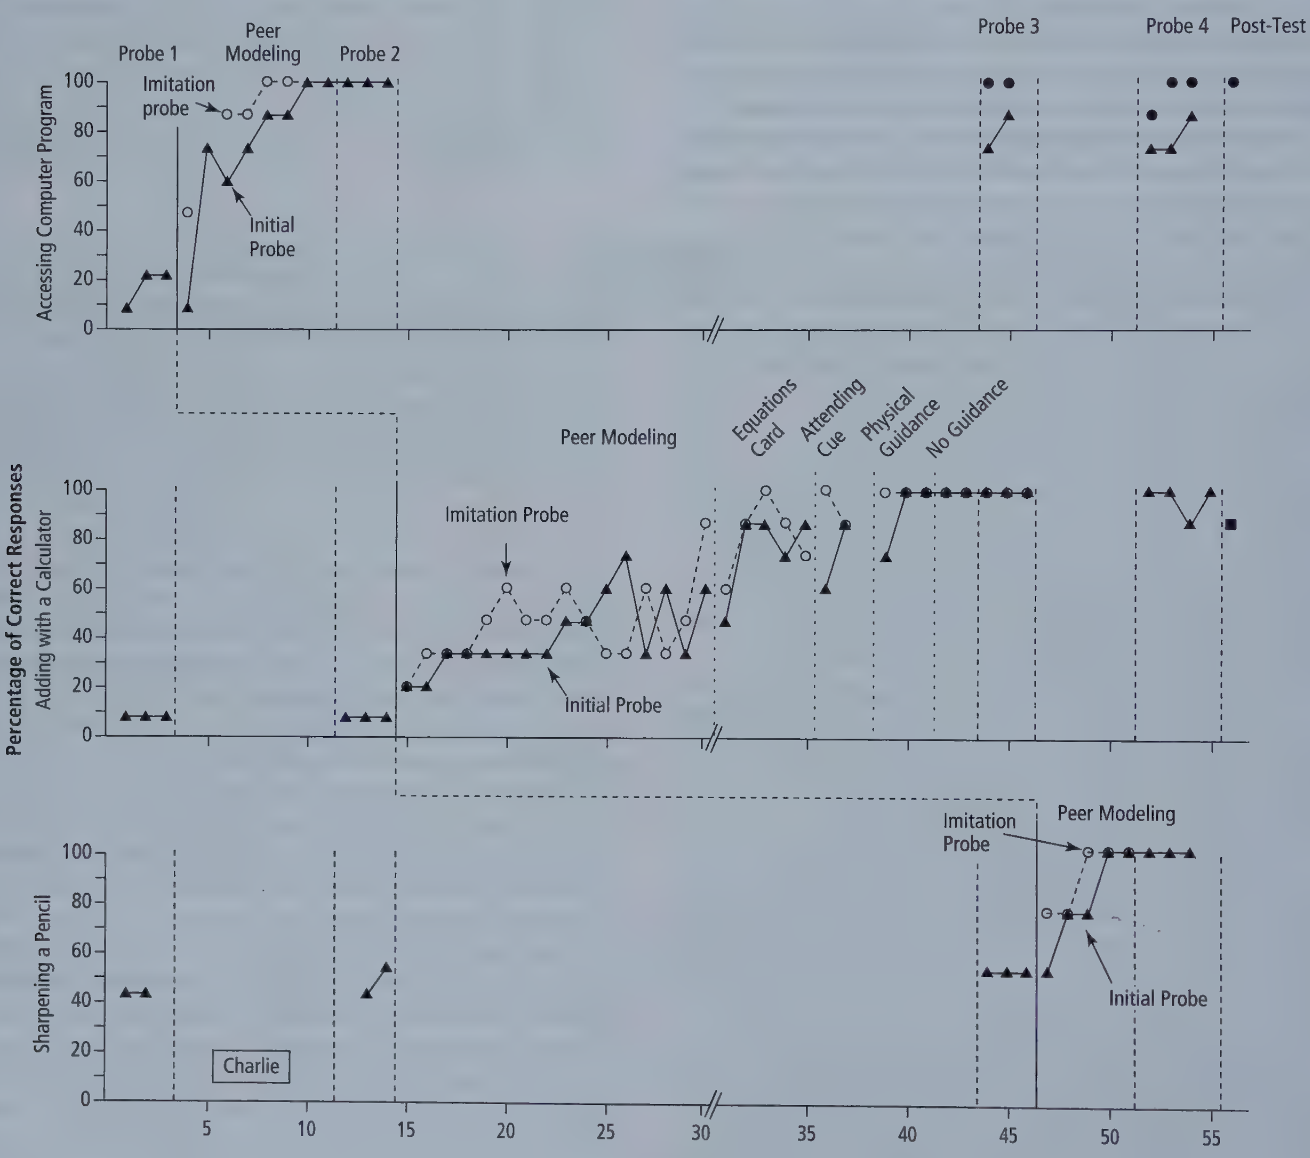

Figure 23.9 Percentage of steps performed correctly by Charlie for the three response chains. Triangles represent percentage of steps correct in initial probes; open circles represent percentage of steps correct in imitation probes.

Test and colleagues (1990) used total-task chaining with a least-to-most prompting procedure to teach two adolescents with severe intellectual disabilities to use a public telephone.[1] After identifying and validating a 17-step task analysis, baseline data were obtained by giving the students a 3 × 5 index card with their home phone number and two dimes, and directing them to "phone home." During training, a least-to-most prompting procedure consisting of three levels of prompts (verbal, verbal plus gesture, and verbal plus guidance) was implemented when errors occurred on any of the 17 steps that made up the task analysis. Each instructional session consisted of two training trials followed by a probe to measure the number of independent steps completed. In addition, generalization probes were conducted in two other settings at least once per week.

Results showed that the combination of total-task chaining plus prompts increased the number of steps in the task analysis performed correctly by each student and that the skills generalized to two community-based settings (see Figure 23.10). Test and colleagues (1990) concluded that total-task chaining, especially as used within the context of a two-per-week training regimen, offered benefits to practitioners working with learners in community-based settings.

Backward Chaining

When a **backward chaining** procedure is used, all the behaviors identified in the task analysis are initially completed by the trainer, except for the final behavior in the chain. When the learner performs the final behavior in the sequence at the predetermined criterion level, reinforcement is delivered. Next, reinforcement is delivered when the last and the next-to-last behaviors in the sequence are performed to criterion. Subsequently, reinforcement is delivered when the last three behaviors are performed to criterion. This sequence proceeds backward through the chain until all the steps in the task analysis have been introduced in reverse order and practiced cumulatively.

Pierrel and Sherman (1963) conducted a classic demonstration of backward chaining at Brown University with a white rat named Barnabus. Pierrel and Sherman taught Barnabus to climb a spiral staircase, push down and cross a drawbridge, climb a ladder, pull a toy car by a chain, enter the car and pedal through a tunnel, climb a flight of stairs, run through an enclosed tube, enter an elevator, raise a miniature replica of the Brown University flag, exit the elevator, and finally press a bar for which he received a pellet of food. Barnabus became so famous for his performance of this elaborate sequence that he acquired the reputation of being "the rat with a college education." This chain of 11 responses was trained by initially conditioning the last response in the sequence (the bar press) in the presence of a buzzer sound, which was established as the S^D for the bar press. Then the next-to-last response in the sequence (exiting the elevator) was conditioned in the presence of the elevator at the bottom of the shaft. Each response in the chain was added in turn so that a discrete stimulus served as the S^D for the next response and as the conditioned reinforcer for the preceding response.[2]

To illustrate backward chaining with a classroom example, let us suppose that a preschool teacher wants to teach a student to tie his shoes. First, the teacher conducts a task analysis of shoe tying and puts the component behaviors in logical sequence.

1. Cross over laces on the shoe.
2. Tie a knot.
3. Make a loop with the lace on the right side of the shoe, and hold it in the right hand.
4. With the left hand, wrap the other lace around the loop.
5. Use the index or middle finger of the left hand to push the left lace through the opening between the laces.
6. Grasp both loops, one in each hand.
7. Draw the loops snug.

The teacher begins by training with the last step in the sequence, Step 7, until the student is able to complete it without mistakes for three consecutive trials. After each correct trial at Step 7, reinforcement is delivered. The teacher then introduces the next-to-last step, Step 6, and begins training the student to perform that step and the final step in the chain. Reinforcement is

contingent on the successful performance of Steps 6 and 7. The teacher then introduces Step 5, making sure that the training step and all previously learned steps (i.e., Steps 5, 6, and 7) are executed in the proper sequence prior to reinforcement. The teacher can use supplemental response prompts to evoke correct responding on behavior at any step. However, any supplemental response prompts—verbal, pictorial, demonstration, or physical—introduced during training must be faded later in the program so that the student's behavior comes under stimulus control of the naturally occurring S^Ds.

With backward chaining, the first behavior the learner performs independently produces the terminal reinforcement: The shoe is tied. The next-to-last response produces the onset of a stimulus condition that reinforces that step and serves as an S^D for the last behavior, which is now being established in the learner's behavioral repertoire. This reinforcing sequence is repeated for the remainder of the steps.

Hagopian, Farrell, and Amari (1996) combined backward chaining with fading to reduce the life-threatening behavior of Josh, a 12-year-old boy with autism and intellectual disabilities. Because of medical complications associated with a variety of gastrointestinal factors, frequent vomiting, and constipation during the 6 months prior to the study, Josh refused to ingest any food or liquids by mouth. Indeed, when he did ingest food by mouth previously, he expelled it.

Over the 70-day course of Josh's treatment program, data were collected on liquid acceptance, expulsions, swallows, and avoidance of the target behavior: drinking water from a cup. After baseline was collected on Josh's ability to swallow 10 cc of water, a swallow condition without water was implemented. An empty syringe was placed and depressed in his mouth, and he was directed to swallow. Next, the syringe was filled with a small volume of water, and reinforcement delivered when Josh swallowed the water. In subsequent phases, the volume of water in the syringe was gradually increased from 0.2 cc to 0.5 cc to 1 cc, and ultimately to 3 cc. To earn reinforcement in subsequent conditions, Josh had to emit the target chain using at first 3 cc of water from a cup to ultimately 30 cc of water. At the end of the study, a successful generalization probe was implemented with 90 cc of a mixture of water and juice.

The results showed that the chaining procedure improved Josh's ability to emit the target chain (see Figure 23.11). Hagopian and colleagues explained their procedure this way:

> We began by targeting a preexisting response (swallowing), which was the third and final response in the chain of behaviors that constitute drinking from a cup. Next, reinforcement was delivered for the last two responses in the chain (accepting and swallowing). Finally, reinforcement was delivered only when all three responses in the chain occurred. (p. 575)

A primary advantage of backward chaining is that the learner contacts the chain's terminal reinforcer on every instructional trial. As a direct outcome of reinforcement, the stimulus that is present at the time of reinforcement increases its discriminative properties. Further, the repeated reinforcement of all behaviors in the chain increases the discriminative capability of all the stimuli associated with these behaviors and with the reinforcer. The main disadvantage of backward chaining is that the potential passive participation of the learner in earlier steps in the chain may limit the total number of responses made during any given training session.

Backward Chaining with Leap Aheads

Spooner, Spooner, and Ulicny (1986) described a variation of backward chaining they called backward chaining with leap aheads. **Backward chaining with leap aheads** follows essentially the same procedures as backward chaining, except that not every step in the task analysis is trained. Selected steps are simply probed. The purpose of the leap-aheads modification is to decrease the total training time needed to learn the chain. With conventional backward chaining, the stepwise

Figure 23.12 Essential features of forward, total-task, backward, and backward chaining with leap aheads.

Forward Chaining	Total-Task Chaining	Backward Chaining	Backward Chaining with Leap Aheads
Behaviors identified in the task analysis are taught in their naturally occurring order. Specifically, reinforcement is delivered when the predetermined criterion for the performance of the first behavior in the sequence is achieved. Trainer completes the remaining tasks in the chain, or assists the learner in doing so. Next, reinforcement is delivered for criterion completion of Steps 1 and 2. Succeeding steps require the cumulative performance of all previous steps in the correct order.	A variation of forward chaining in which the learner receives training on each step in the task analysis during every session. The trainer provides assistance for any steps the learner is unable to perform independently, and the chain is trained until the learner is able to perform all the behaviors in the sequence to the predetermined criterion.	Tasks are taught in a "backward" (last-to-first) sequence. All the task-analysis-identified behaviors are initially completed by the trainer, except for the final behavior in the chain. When the learner performs the final behavior in the sequence at the predetermined criterion level, reinforcement is delivered. Next, reinforcement is delivered when the combined next-to-last and last behaviors in the sequence are performed to criterion. Subsequently, reinforcement is delivered when the combined sequence of the last three behaviors are performed to criterion. This series proceeds in reverse fashion through the chain until all the steps in the task analysis have been introduced in reverse order and practiced cumulatively.	This type of chaining follows essentially the same procedures as backward chaining, except that not every step in the reverse execution of the task analysis is trained. Selected steps are simply probed. Tasks that the learner can perform are skipped, and the trainer "leaps ahead" to the next unmastered task, thereby decreasing total training time for the chain.

repetition of the behaviors in the sequence may slow down the learning process, especially when the learner has mastered a few of the steps in the chain. For instance, in the previous shoe-tying illustration, the child might perform Step 7, the last behavior in the sequence, and then leap ahead to Step 4 because Steps 5 and 6 are in her repertoire. It is important to remember, however, that the learner must still perform Steps 5 and 6 correctly and in sequence with the other steps to receive reinforcement.

Figure 23.12 describes the essential features of forward, total-task, backward, and backward chaining with leap aheads.

CHOOSING A CHAINING METHOD

Forward chaining, total-task chaining, backward chaining, and backward chaining with leap aheads have each shown effectiveness with a wide range of self-care, vocational, recreational, and independent-living behaviors. Which chaining procedure should be the method of first choice? Research conducted to date does not suggest a definitive answer. Furthermore, research does not suggest a clear protocol for whether unfinished links in a chain should be completed by the teacher or the student, or left unfinished until the next training trial. Bancroft, Weiss, Libby, and Ahearn (2011) showed that whereas the majority of students in their study learned a chain faster under the student condition, this result was not universal for all students.

After examining evidence reported between 1980 and 2001, Kazdin (2001) concluded: "Direct comparisons have not established that one [forward chaining, backward chaining, or total-task chaining] is consistently more effective than the other" (p. 49). A study by Slocum and Tiger (2011) found forward and backward chaining procedures to be similarly effective.

Seaver and Bourret (2014) stated, "When all teaching procedures are equally efficient for a particular individual, a practitioner may take student preference . . . teacher preference, and procedural integrity into consideration" (p. 791). Anecdotal evidence, logical analysis, and the behavior analyst's experience with the learner may also provide direction. Miltenberger (2001) and Test et al. (1990) concluded that using total-task chaining may be warranted (a) when the student can perform several of the tasks in the chain, but needs to learn them in sequence; (b) when the student has an imitative repertoire; (c) when the student has moderate to severe disabilities; and/or (d) when the task sequence or cycle is not very long or complex. Likewise, Bancroft et al. (2011) advised considering other factors—the learner's ability to tolerate physical guidance, the attention span of the learner, or the total amount of training time available to devote to learning the chain—when deciding which method to use.

Uncertainty about which approach to follow may be minimized by conducting a personalized task analysis for the learner, systematically applying the single- or multiple-opportunity method to determine the starting point for instruction, and relying on empirically sound data-based studies in the literature. Further, doubt can be reduced by ascertaining if an individual's past history with any of the chaining procedures or variations favors one method over another, and/or by collecting formative evaluation data (i.e., measurements of the target behavior during treatment) and summative evaluation data (i.e., measurement of behavior after treatment) on the proposed approach, to determine its efficacy for that person.

DISRUPTING AND BREAKING BEHAVIOR CHAINS

Thus far, our discussion has focused on procedures for building behavior chains—that is, constructing a sequence of stimulus conditions and associated responses such that when individual components are joined, the chain of behavior results that produces reinforcement. As stated earlier, each stimulus linking two responses in a chain serves the dual functions of conditioned reinforcer for the response that produced it and discriminative stimulus for the next response in the chain.

Practitioners have used chaining to expand the repertoires of a wide range of learners. Knowing how to link behaviors into a practical chain, however, is not always sufficient. Behavior analysts should also know how to disrupt or break behavior chains that are maladaptive or inappropriate (e.g., consuming too much food, texting while driving). Behavior chains can be disrupted or broken with six methods: extinction, satiation, unchaining, interrupting the chain, substituting the S^D, and extending the chain with time delays.

In a series of three experiments, Kuhn, Lerman, Vorndran, and Addison (2006) evaluated the effects of extinction, satiation, and unchaining on responding by children with disabilities in a previously taught two-response chain. The chain in each experiment went like this: S1 (therapist shows child a small box containing a preferred food item and closes the box) → R1 (child signs "open") → S2 (therapist opens box of food) → R2 (child signs "eat" or "popcorn") → (child receives food).

Extinction

To break or interrupt a chain using extinction, the practitioner withholds reinforcement for one or more responses in the chain. Kuhn et al. (2006) applied extinction to the final response in the chain: "R1 ('open') resulted in the box opening as before, but the box was closed and no food was delivered contingent on R2 ('eat' or 'popcorn')" (p. 273). Extinction for R2 resulted in immediate decreases in both R1 and R2 by all four participants (Figure 23.13 shows results for two children). Extending their findings to a two-response chain of aggressive behavior consisting of arm grabbing and hair pulling, Kuhn and colleagues suggested that treating hair pulling with extinction would likely result in decreased arm grabbling.

Satiation

To break or interrupt a chain using satiation, the practitioner provides unlimited access to the reinforcer (an abolishing operation) for the last response in the chain. As a result, the chain's final response will likely abate because of the decreased effectiveness of the reinforcer. Responses earlier in the chain would be expected to decrease as well because the effectiveness of the stimulus changes as conditioned reinforcers for earlier responses depends upon their association with the chain's terminal reinforcer.

Kuhn and colleagues (2006) evaluated this satiation condition. Prior to each session, the child was given free access to food for the duration of "satiation periods" ranging from 25 to 30 minutes. Presession access to the chain's terminal reinforcer decreased both responses in the chain (see Figure 23.14). R2 ("eat") decreased as a direct result of presession access to food; R1 ("open") decreased because presession access to food weakened an opened food box as a conditioned reinforcer.

Addison, 2006, *Journal of Applied Behavior Analysis, 39*, p. 272. Copyright 2006 by the Society for the Experimental Analysis of Behavior, Inc. Used with permission.

Unchaining

Unchaining—a term introduced by Kuhn et al. (2006) for a procedure described by Michael (2000)—occurs when, in the case of a two-response chain, R2 produces reinforcement not only in the presence of S2 (as usual) but also in the absence of S2. In Michael's example, a food-deprived rat's first response (R1) turns on a tone, in the presence of which a second response (R2) produces food. In the unchaining procedure (Michael called it *unpairing*), R1 continues to produce the tone, but R2 results in food regardless of the tone's presence. In theory, R1 will decrease because its immediate consequence, the tone, loses its reinforcing effectiveness as a conditioned reinforcer because it no longer functions as a discriminative stimulus (S^D) for food. Thus, unchaining disrupts R1 while leaving R2 intact.

The unchaining procedure used by Kuhn and colleagues (2006) was implemented as follows:

> Reinforcement was delivered contingent on R2 regardless of when it occurred. That is, the child received a small piece of food contingent on completing the chain (i.e., R1, then R2) and contingent on R2 alone. Thus, R2 produced food regardless of whether the box was open. The purpose of this condition was to look at the effects of unchaining R1 (i.e., communicating to open the box) and R2 (i.e., communicating for food) on the response chain. Initially for all children, the reinforcer for signing "eat" (or "popcorn" for Timmy) outside the chain "open-eat" was placed behind the therapist's back, as well as in the box, so that the therapist could deliver the reinforcer without opening the box. Beginning with Session 16 (first unchaining phase) and Session 42 (second unchaining phase), the reinforcer was placed on a plate on the table in front of Don, next to the box containing additional reinforcers. The reinforcer on the plate was provided contingent on occurrences of the "eat" response outside the context of the chain. (p. 274)

Figure 23.15 shows results for the three children who participated in the experiment. Unchaining had little effect on Bonnie, as she continued to emit both responses in the chain throughout the unchaining condition. In contrast, after three or four sessions of unchaining, Timmy no longer emitted R1. Unchaining had no effect on Don's behavior until researchers modified the procedure by making the food visible on a plate. This resulted in a decrease in R1 ("open") responses.

Although unchaining may show promise as a method for disrupting earlier responses in a chain, Kuhn et al.'s (2006) data do not show that the effects of unchaining are as powerful, or as immediate, as extinction or satiation methods.

Interrupting the Chain

The **behavior chain interruption strategy** (BCIS) relies on the participant's skill to initially perform all the critical elements of a chain independently, but the chain is then interrupted, or a link in the chain is made unavailable, at a predetermined link so that another behavior can be emitted or prompted. Initially developed to increase speech and oral responding (Goetz, Gee, & Sailer, 1985; Hunt & Goetz, 1988), the BCIS has been extended into pictorial communication systems (Roberts-Pennell & Sigafoos, 1999), manual signing (Romer, Cullinan, & Schoenberg, 1994), switch activation (Gee, Graham, Goetz, Oshima, & Yoshioka, 1991), and mand training (Albert, Carbone, Murray, Hagerty, & Sweeney-Kerwin, 2012; Hall & Sundberg, 1987).

The BCIS works as follows. First, an assessment is conducted to determine if the person can independently complete a chain of two or more components. Figure 23.16 shows an example of how a toast-making chain, divided into five steps, was assessed across degrees of distress and attempts to complete when specific steps were blocked by an observer. Degree of distress was ranked on a 3-point scale, and attempts were registered using a dichotomous scale (i.e., yes or no).

With respect to using BCIS in applied settings to increase behavior, a chain is selected based on the assumption that when it is interrupted, it will not be unduly distressful for the individual. In other words, care is taken that the interruption does not precipitate the person becoming episodic or self-injurious. After collecting baseline on a target behavior (e.g., vocalizations), the person is directed to start the chain (e.g., "Make toast."). At a predetermined step in the chain—say, Step 3 (e.g., "Push down")—the individual's ability to complete that step is restricted. For example, the practitioner might passively block access to the toaster momentarily. The person would then be prompted, "What do you want?" A vocalization, previously not in the learner's repertoire, would be required for the chain to be completed. That is, the person would be prompted to say, "Push down."

A procedural variation of BCIS, the **interrupted chain procedure** (ICP), entails arranging the environment such that the learner is unable to continue the chain at a predetermined step. A practitioner implementing the ICP in the toast-making chain might conceal the toaster and, after the learner has obtained a slice of bread, ask, "What do you want?" The verbal prompt may function as a motivating operation that evokes the learner's response, "Toaster, please," to obtain the toaster and complete the chain.

Although the exact behavioral mechanisms responsible for improved performance using BCIS and ICP are still subject to scientific inquiry, analysis, and explanation, field-based research efforts, including those examining generalized outcomes (Grunsell & Carter, 2002), have established them as efficacious approaches, especially for persons with severe disabilities. For example, Carter and Grunsell's (2001) review of the literature on the efficacy of BCIS shows that it is positive and beneficial. In their view,

> The BCIS may be seen as empirically supported and complementary to other naturalistic techniques. . . . A small, but growing body of research literature has demonstrated that individuals with severe disabilities have acquired requesting with the BCIS. In addition, research demonstrates that implementation of the BCIS may increase the rate of requesting. (p. 48)

The assumption underlying BCIS assessment is that "persistence in task completion and emotional response to the interruption would serve as operational definitions of high motivation for task completion" (Goetz et al., 1985, p. 23). Because momentarily interrupting a chain detains the learner from obtaining the reinforcer for completing the chain, the procedure may function as a conditioned motivation operation that evokes additional behavior required to continue and complete the chain (see Chapter 16). "By interrupting the chains at the point at which these additional objects (or actions) are needed,

From "Using a Chain Interruption Strategy to Teach Communication Skills to Students with Severe Disabilities," by L. Goetz, K. Gee, & W. Sailor, *Journal of the Association of Persons with Severe Handicaps, 1985, 13*(1), p. 24. Copyright by the Association for Persons with Severe Handicaps. Used by permission.

practitioners can momentarily establish them as reinforcers and contrive opportunities to teach a wider variety of mands" (Albert et al., 2012, p.73).

In any case, the literature is becoming increasingly clear that the BCIS/ICP consists of several components and features that make it useful as a behavior change tactic in natural settings. Participants exposed to interrupted chain procedures can learn to perform nontrained tasks and responses, thereby increasing the efficiency of the procedure (Albert et al., 2012; Carter & Grunsell, 2001). As Albert el al. state, "By interrupting the chains at the point at which these additional objects (or actions) are needed, practitioners can momentarily establish them as reinforcers and contrive opportunities to teach a wider variety of mands" (p. 73). Figure 23.17 reviews key components and features of BCIS/ICPs.

Substituting an Initial S^D for an Alternative Chain

When a specific S^D sets an inappropriate chain in motion, blocking that S^D completely and substituting the initial S^D for a preferred chain may be effective. For example, if an ashtray next to a favorite chair (S_1) evokes a chain of finding a pack of cigarettes (R_1), finding a lighter (R_2), and firing up a smoke (R_3), replacing the ash tray with a TV remote, a newspaper, or a book may occasion one or more desirable sequences of responses.

Extending the Chain with Time Delays

Martin and Pear (2016) suggested that a behavior chain that reinforces excessive food consumption can be broken by introducing links requiring the individual to place the eating utensil on the table between bites, or introducing a 3- to 5-sec time delay before the next bite can be initiated. In an undesirable chain, "the person gets ready to consume the next bite before even finishing the present one" (p. 111). A more desirable chain separates these components and introduces brief delays.

TROUBLESHOOTING CHAINS

With respect to separating chain components, let us consider the case of a restaurant trainee who has been taught to bus tables. Upon completion of the training program, the trainee was able to perform each of the necessary behaviors in the table-busing chain accurately and proficiently (see Figure 23.18, upper panel). However, on the job site, the new employee started to emit an inappropriate sequence of

Figure 23.17 Key components and features of the BCIS.

- Instruction begins in the middle of the chain sequence, not the start, differing from forward and backward chaining procedures. Because the instruction begins in the middle of the sequence, interrupting the sequence might function as a transitive conditioned motivating operation or negative reinforcer, the removal of which increases behavior.
- Procedurally, the BCIS is predicated on an assessment that verifies that the person is able to complete the chain independently, but experiences moderate distress when the chain is interrupted in the middle of the sequence.
- Verbal prompts are used at the point of interruption (e.g., "What do you want?"), but a full range of response prompts—modeling and physical guidance—has also been employed.
- Interruption training occurs in the natural setting (e.g., a water basin for washing hair; the microwave oven for making cookies).
- Maintenance, generalization, and social validity data, although not overwhelmingly evident in every study, are sufficiently robust to suggest that the BCIS be included with other interventions (e.g., mand-model, time delay, and incidental teaching).

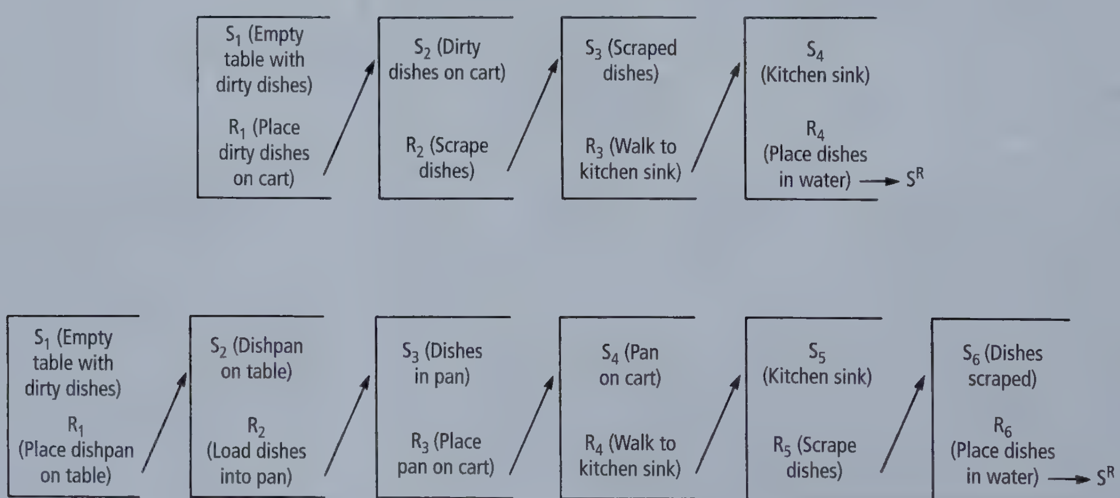

Figure 23.18 Illustration of an original behavior chain (upper panel) and its revision (lower panel) to break an inappropriate response sequence.

behaviors. Specifically, in the presence of dirty dishes on the empty table, the individual scraped excess food scraps onto the table itself, instead of placing the dirty items on the food cart. In other words, the initial S^D for the table-busing chain, the empty table with the dirty plates, was setting the occasion for a response (dish scraping) that should have occurred later in the chain.

To troubleshoot this inappropriate chain and determine a course of action, the behavior analyst should consider several possible sources of difficulty, including (a) re-examining the S^Ds and responses S_1-R_1-S_2-R_2; (b) determining whether similar S^Ds cue different responses; (c) analyzing the job setting to identify relevant and irrelevant S^Ds; (d) determining whether S^Ds in the job setting differ from training S^Ds; and (e) identifying the presence of novel stimuli in the environment.

Re-examine the S^D and Response Sequence

Kuhn et al. (2006) indicated that appropriate chains can be broken inadvertently and the entire chain, or key links within the chain, can be compromised when parents, teachers, and/or caregivers unwittingly reinforce an inappropriate sequence. They stated,

> . . . if a series of appropriate behaviors are inadvertently linked in a chain and the contingencies change for just some members of the chain (e.g., if a new caregiver begins to reinforce the terminal response whether or not it followed earlier responses in the chain), earlier appropriate behaviors could be eliminated (p. 265).

So, by re-examining the S^D and response sequence, a more appropriate arrangement might be contrived.

Determine Whether Similar S^Ds Cue Different Responses

Figure 23.18 (upper panel) shows two similar S^Ds—dirty dishes on the empty table (S_1) and dirty dishes on the cart (S_2)—which might have contributed to the scraping of food onto the table. In other words, R_2 (scrape dishes) might have come under the control of S_1 (dirty dishes on table). Figure 23.18 (lower panel) shows how the behavior analyst corrected the sequence by rearranging the S^Ds and their associated responses. Scraping the dishes is now the fifth response in the chain (R_5), and it occurs at the kitchen sink, an area away from the restaurant tables and diners. Thus, any potential confusion would be reduced or eliminated.

Analyze the Natural Setting to Identify Relevant and Irrelevant S^Ds

The training program should be designed so that the learner is trained to discriminate the relevant (i.e., critical) components of a stimulus from the irrelevant variations. Figure 23.18 (lower panel) shows at least two relevant characteristics of S_1: an empty table and the presence of dirty dishes on that table. An irrelevant stimulus might be the location of the table in the restaurant, the number of place settings on the table, or the arrangement of the place settings. A relevant characteristic of S_5, the presence of the kitchen sink, would be water faucets, the sink configuration, or dirty dishes. Finally, irrelevant stimuli might be the size of the kitchen sink and the type or style of faucets.

Determine Whether S^Ds in the Natural Setting Differ from Training S^Ds

It is possible that variations of the S^Ds cannot be taught during simulated training phases because natural conditions cannot be replicable or governmental regulations are prohibitive. For example, instrument pilots executing a complex chain of approach and landing maneuvers for a "circling approach" to an airport as part of a competency check, can only do that maneuver in a real airplane at an airport. Simulated approaches are not allowed. Hence, it is recommended that the final training session, at least for selected chains, be conducted in the natural setting where the behavior chain is expected to be performed. This allows any differences that exist to be recognized by the trainer and subsequent discrimination training to be further refined on site.

Identify the Presence of Novel Stimuli in the Environment

The presence of a novel stimulus unexpected in the original training situation can also prompt the occurrence of an inappropriate chain. In the restaurant example, the presence of a crowd of customers may set the occasion for the chain to be performed out of sequence. Likewise, distracting stimuli (e.g., customers coming and going, tips left on the table) may set the occasion for an inappropriate chain. Also, a coworker might unwittingly give contradictory instructions to the trainee. In any of these situations, the novel stimuli should be identified and the learner taught to discriminate them along with other S^Ds in the environment.

FACTORS AFFECTING THE PERFORMANCE OF BEHAVIOR CHAINS

Several factors affect the performance of a behavior chain. The following sections outline these factors and provide recommendations for addressing them.

Completeness of the Task Analysis

The more complete and accurate the task analysis, the more progress the person can make through the sequence. If the elements making up the chain are not sequenced appropriately, or if the corresponding S^Ds are not identified for each response, learning the chain will be more difficult.

The behavior analyst should remember two key points when attempting to develop an accurate task analysis. First, planning must occur before training. The time devoted to constructing and validating the task analysis is well spent. Second, after the task analysis is constructed, training should begin with the expectation that adjustments in the task analysis, or the use of more intrusive prompts, may be needed at various steps in the task analysis. For example, McWilliams and colleagues (1990) noted that one of their students required extensive trials and more intrusive prompts with a few steps in the task analysis before improved performance was obtained.

Length or Complexity of the Chain

Longer or more complex behavior chains take more time to learn than shorter or less complex behavior chains. Likewise, if two or more chain clusters are linked, practitioners can anticipate that training will be longer.

Schedule of Reinforcement

When a reinforcer is presented subsequent to the performance of a behavior in a chain, it affects each of the responses making up the chain. However, the effect on each response is not identical. For example, in backward chaining, responses performed at the end of the chain are strengthened faster than responses made earlier in the chain because they are reinforced more frequently. The behavior analyst is advised to remember two points: (a) A chain can be maintained if an appropriate schedule of reinforcement is used (see Chapter 13), and (b) the number of responses in a chain may need to be considered when defining the schedule of reinforcement.

Stimulus Variation

Bellamy, Horner, and Inman (1979) provided an excellent pictorial representation of how stimulus variation affects a learner's performance of a chain. The upper photograph in Figure 23.19 shows a cam switch bearing before and after its placement on a cam switch axle. The lower photograph shows the four different types of bearings that can be used in the assembly process. Any bearing sharing two critical features—a 1.12-cm circular hole in the center and one or more hex nut slots on its face—should evoke placing it on a cam switch axle. Bearings without these features, regardless of the presence of irrelevant features (e.g., color, material composition, weight), should not occasion the response.

If possible, the behavior analyst should introduce all possible variations of the S^D that the learner will encounter. Regardless of the behavior chain, presentation of stimulus variations increases the probability that the correct response will occur in their presence. This includes, for example, in an assembly task, various canisters and shafts; with dressing skills, different fasteners, zippers, and buttons; and with tooth brushing, assorted toothpaste tubes and pumps and brushes.

Response Variation

Often when stimulus variations occur, response variation also must occur to produce the same effect. Again, Bellamy and colleagues (1979) provided an illustration with the cam shaft assembly. In the upper-left photograph of Figure 23.20, the bearing has been placed on the cam shaft, and the retaining clip is being positioned for placement with a pair of nose pliers.

Figure 23.19 Upper panel: A cam switch bearing before and after placement on a cam switch axle. Lower panel: Four different types of bearings used in cam switch assembly.

From *Vocational Habilitation of Severely Retarded Adults*, pp. 40 & 42, by G. T. Bellamy, R. H. Horner, and D. P. Inman, 1979, Austin, TX: PRO-ED. Copyright 1979 by Pro-Ed. Reprinted by permission.

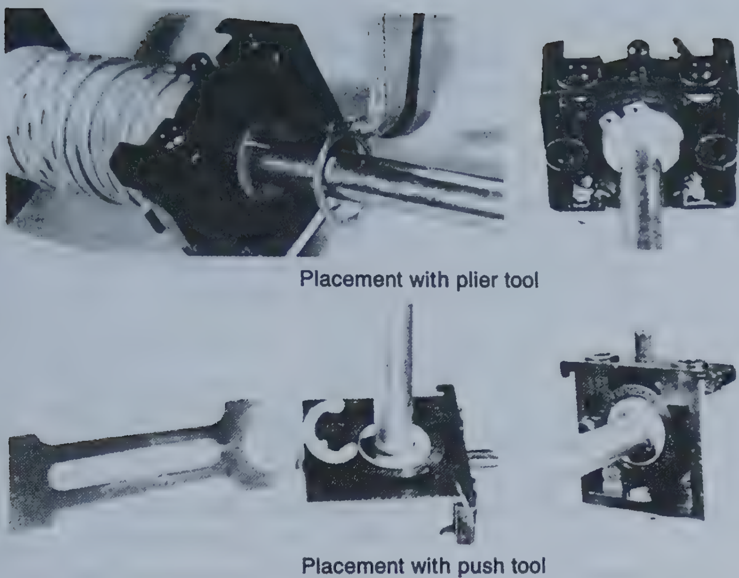

Figure 23.20 Two ways that retaining rings are applied to affix bearings to cam axles.

From *Vocational Habilitation of Severely Retarded Adults*, p. 44, by G. T. Bellamy, R. H. Horner, and D. P. Inman, 1979, Austin, TX: PRO-ED. Copyright 1979 by Pro-Ed. Reprinted by permission.

The upper-right photograph shows the clip in position. The lower-left photograph shows a different bearing configuration (i.e., the S^D is different) requiring a different response. Instead of the retaining clip being lifted over the bearing cap with pliers, it must be pushed over the cap with a wrench-type tool. The response of lifting or pushing has changed, as has the response of selecting the appropriate tool. Thus, the behavior analyst should be aware that when stimulus variation is introduced, training, or retraining of responses, within the chain may be required.

SUMMARY

Behavior Chain Defined

1. A behavior chain is a linked sequence of responses leading to a terminal outcome. Each response, and its associated stimulus condition, produces a change that functions as conditioned reinforcement for that previous response and as a discriminative stimulus for the next response in the chain. Reinforcement for the last response in a chain maintains the reinforcing effectiveness of the stimulus changes produced by all previous responses in the chain.

2. Each stimulus that links two sequential responses in a chain serves dual functions: It is a conditioned reinforcer for the response that produced it and an S^D for the next response in the chain.

3. A behavior chain has three important characteristics: (a) It involves the performance of a specific series of discrete responses; (b) the performance of each behavior in the sequence produces a stimulus change in the environment in such a way that it yields conditioned reinforcement for the preceding response and serves as an S^D for the next response; and (c) the responses within the chain must be performed in a specific sequence, and in close temporal succession.

4. In a behavior chain with a limited hold, a sequence of behaviors must be performed correctly and within a specific time for reinforcement to be delivered. Proficient responding is a distinguishing feature of chains with limited holds.

5. If a learner takes too much time to complete one or more component responses, the behavior analysis can implement contingencies focusing on the proficiency of performance. Setting a time criterion for the onset and completion of each response within the chain is one way to do this; another is to set a time criterion for completion of the total chain.

Rationale for Chaining

6. Whereas a behavior chain denotes a particular sequence of stimuli and responses ending in reinforcement, chaining refers to various methods for linking specific sequences of stimuli and responses to form new performances.

7. Chaining refers to the way these specific sequences of stimuli and responses are linked to form new performances. In forward chaining, behaviors are linked beginning with the first behavior in the sequence. In backward chaining, the behaviors are linked beginning with the last behavior in the sequence. Forward and backward chaining have variations available.

8. A behavior analyst should be skilled in building behavior chains for three reasons: (a) Chains can be used to improve independent-living skills; (b) chains can provide the means by which other behaviors can be combined into more complex sequences; and (c) chains can be combined with other procedures to build behavioral repertoires in generalized settings.

Establishing Behavior Chains with Task Analysis

9. Task analysis involves breaking a complex skill into smaller, teachable units, the product of which is a series of sequentially ordered steps or tasks.

10. The purpose of constructing and validating a task analysis is to determine the sequence of stepwise critical behaviors that constitute the complete task and that would lead to it being individualized for the learner and performed efficiently. Task analyses can be constructed by observing a competent performer, by executing the task yourself, by asking an expert, and by trial and error.

11. The purpose of assessing mastery level is to determine which components of the task analysis can already be performed independently. Assessment can be conducted with the single-opportunity or multiple-opportunity method.

Behavior Chaining Methods

12. In forward chaining, the behaviors identified in the task analysis are taught in their natural sequence. Specifically, reinforcement is delivered when the predetermined criterion for the first behavior in the sequence is achieved. Thereafter, reinforcement is delivered for criterion completion of Steps 1 and 2. With each successive step, reinforcement is delivered contingent on the correct performance of all steps trained thus far.

13. Total-task chaining is a variation of forward chaining in which the learner receives training on each step in the task analysis during every session. Trainer assistance is provided using response prompts with any step the individual is not able to perform. The chain is trained until the learner performs all the behaviors in the sequence to criterion.

14. In backward chaining, all the steps identified in the task analysis are completed by the trainer, except the last one. When the final step in the sequence is performed to criterion, reinforcement is delivered. Next, reinforcement is delivered when the next-to-last step and the last step are performed. Subsequently, the individual must perform the last three steps before reinforcement is delivered, and so on. The primary advantage of backward chaining is that the learner contacts the chain's terminal reinforcer on every instructional trial.

15. Backward chaining with leap aheads follows essentially the same procedures as in backward chaining, except that not every step in the task analysis is trained. The leap-aheads modification provides for probing or assessing untrained behaviors in the sequence. Its purpose is to speed up training of the behavior chain.

Choosing a Chaining Method

16. The decision to use forward chaining, total-task chaining, backward chaining, or backward chaining with leap aheads should be based on the results of a task analysis assessment; empirically sound data-based studies; and a functional evaluation, taking into consideration the cognitive, physical, motoric, and attention abilities of the individual.

Disrupting and Breaking Behavior Chains

17. Behavior chains can be interrupted or broken in at least six ways. These include extinction, satiation, unchaining, interrupting the chain, substituting an S^D, or extending the chain and building in time delays.

Troubleshooting Chains

18. To troubleshoot an inappropriate chain, the behavior analyst should consider (a) re-examining the S^Ds and responses S_1-R_1-S_2-R_2, (b) determining whether similar S^Ds cue different responses, (c) analyzing the job setting to identify relevant and irrelevant S^Ds, (d) determining whether S^Ds in the job setting differ from training S^Ds, and (e) identifying the presence of novel stimuli in the environment.

Factors Affecting the Performance of Behavior Chains

19. Factors affecting the performance of a behavior chain include (a) completeness of the task analysis, (b) length or complexity of the chain, (c) schedule of reinforcement, (d) stimulus variation, and (e) response variation.

MULTIPLE-CHOICE QUESTIONS

1. Each of the following is an example of a behavior except:
   a. Mowing the lawn
   b. Brushing your teeth
   c. Blinking your eye
   d. Writing your name
   Hint: (See "Behavior Chain Defined")
2. A behavior chain with a limited hold means:
   a. The number of steps in the chain is limited.
   b. The learner must "hold" his/her responses for a specified period of time.
   c. The entire chain or steps within the chain must be completed in a given period of time.
   d. Accuracy of the performance of steps is not important.
   Hint: (See "Behavior Chain Defined")
3. Behavior chains and chaining procedures are important because:
   a. There are many behaviors that are considered behavior chains, and these behaviors lead to more independence in life.
   b. Chaining can be combined with many other teaching procedures so that behaviors can be taught in a variety of contexts.
   c. Chaining is an efficient training procedure-it can be used to combine already existing repertoires of behavior into new behaviors.
   d. All of these
   Hint: (See "Rationale for Chaining")
4. How are forward and backward chaining different?
   a. Forward chaining means the learner learns the steps to the skill in the correct order, and backward chaining means the learner learns the steps in the reverse order.
   b. Forward chaining means the learner learns the first step first in the sequence, and backward chaining means the learner learns the last behavior in the sequence first (but the steps are still learned in the correct sequence).
   c. Forward chaining is a much quicker way to learn a task than backward chaining.
   d. None of these answer choices accurately differentiates between forward and backward chaining.
   Hint: (See "Rationale for Chaining")
5. If you want to create a task analysis for a behavior you have no idea how to do yourself, how could you construct it?
   a. You could find people who are good at the behavior and ask them how to do it.
   b. You could watch people who know how to do the task and observe what they do.
   c. You could go to the literature to see if there are any published task analyses of the behavior.
   d. All of these.
   Hint: (See "Establishing Behavior Chains with Task Analysis")
6. What is a risk of choosing the single-opportunity method of assessment for assessing mastery of a task analysis?
   a. You may underestimate the learner's abilities.
   b. You may inadvertently be teaching the individual the behavior during assessment.
   c. You may frustrate the learner because of the time-consuming nature of this form of assessment.
   d. All of these.
   Hint: (See "Establishing Behavior Chains with Task Analysis")
7. Breaking down longer chains into smaller chains and/or skill clusters, teaching each skill cluster, and then chaining each skill cluster is a variation of which form of behavior chaining?
   a. Forward chaining
   b. Backward chaining
   c. Total task chaining
   d. Backward chaining with leap aheads
   Hint: (See "Behavior Chaining Methods")
8. Peer models have been used to teach children with disabilities to perform complex tasks using which form of chaining?
   a. Forward chaining
   b. Backward chaining
   c. Total task chaining
   d. Backward chaining with leap aheads
   Hint: (See "Behavior Chaining Methods")
9. The behavior chain interruption strategy (BCIS) can be used to:
   a. Teach a complex new behavior chain
   b. Increase speech, picture communication, and microswitch activation
   c. Replace the initial SDs in a chain
   d. All of these
   Hint: (See "Disrupting and Breaking Behavior Chains")

10. Kara has been learning to board a public bus, put money in the slot, and sit in her seat, waiting for her stop. Then, she pushes the button to indicate when she wants to get off. She has practiced this skill in her small hometown, where there are rarely more than five people on the bus. She traveled to Chicago with her parents to visit her aunt. She rode the bus with her parents in Chicago and was unable to do many steps in the chain. For example, she wasn't able to put her money in the slot, and she had difficulty choosing a seat. Her parents noticed that she was very distracted by all the people on the bus, as compared to the few people who are on the bus at home. Which of the following is the most likely reason that Kara wasn't able to perform steps in the chain she had learned so well at home?

a. The S^Ds on the bus were too similar to S^Ds on the bus at home, and so they triggered different responses.

b. The steps of the task were different on this bus than on the one at home.

c. There were novel stimuli present in Chicago that weren't present at home and that interfered with Kara's chain.

d. All of these are reasonable explanations for Kara's trouble.

Hint: (See "Disrupting and Breaking Behavior Chains")

ESSAY-TYPE QUESTIONS

1. Define and give an example of a behavior chain.

   Hint: (See "Behavior Chain Defined")

2. Explain why it is important to teach behavior chains to people.

   Hint: (See "Rationale for Chaining")

3. Assume you want to conduct a task analysis of playing a video game. What are the three different ways you could approach developing that task analysis?

   Hint: (See "Establishing Behavior Chains with Task Analysis")

4. Explain how forward, backward, and total-task chaining are conducted.

   Hint: (See "Behavior Chaining Methods")

5. If Marcus tends to have pizza binges when he is stressed and wants to stop this behavior chain, how could he go about it?

   Hint: (See "Disrupting and Breaking Behavior Chains")

PART 9

Decreasing Behavior with Nonpunishment Procedures

Part 9 describes nonpunishment interventions to decrease or eliminate problem behaviors. Chapter 24 details extinction procedures for problem behaviors linked to behavior maintained by positive reinforcement, negative reinforcement, and automatic reinforcement. This chapter includes sections on extinction effects, variables affecting resistance to extinction, guidelines for using extinction effectively, and when not to use extinction. Chapter 25 describes the four most frequently researched variations of differential reinforcement for decreasing problem behavior: differential reinforcement of (a) incompatible behavior (DRI), (b) alternative behavior (DRA), (c) other behavior (DRO), and (d) low rates of responding (DRL). Examples of applications and guidelines for the effective use of each of these differential reinforcement procedures are provided. Chapter 26 defines, gives examples, and offers guidelines for treating problem behavior by changing the environment before the behavior occurs. Antecedent interventions directed toward problem behaviors are described with respect to function, stimulus control, and contingency independence.

CHAPTER 24

Extinction

LEARNING OBJECTIVES

- State the definition of extinction.
- Compare and contrast the functional and procedural forms of extinction.
- Identify three misuses of the term extinction.
- Compare and contrast the use of extinction with behaviors maintained by positive, negative, and automatic reinforcement.
- Plot and label an extinction curve on a graph.
- Discuss the phenomenon of spontaneous recovery.
- Explain the effect of continuous and intermittent reinforcement on behavior's resistance to extinction.
- Discuss how establishing operations affect resistance to extinction.
- List several behavioral examples that demonstrate how response effort influences a behavior's resistance to extinction.
- List and discuss the ten guidelines for the use of extinction.

> Pavlov had studied a process that was in a sense the reverse of conditioning and took place more slowly. He called it "extinction." In my early notes I sometimes called it "adaptation," because it resembled the slow disappearance of the unconditioned response to a click. My first extinction curve turned up by accident. A rat was pressing the lever in an experiment on satiation when the pellet dispenser jammed. I was not there at the time, and when I returned I found a beautiful curve. The rat had gone on pressing although no pellets were received, at first more rapidly than usual since no time was lost in eating, but then more and more slowly as time wore on. Some oscillation between high and low rates made the cumulative record wavelike.
>
> The change was more orderly than the extinction of a salivary reflex in Pavlov's setting, and I was terribly excited. It was a Friday afternoon and there was no one in the laboratory whom I could tell. All that weekend I crossed streets with particular care and avoided all unnecessary risks to protect my discovery from loss through my death.
>
> In my new laboratory I collected more extinction curves, all with roughly the same wavelike form—the rats pressing rapidly at first but then more and more slowly until they stopped.
>
> —B. F. Skinner (1979, p. 95)

Withholding reinforcement for a previously reinforced behavior decreases the rate of that behavior: a tactic, process, and principle known as *extinction*. As a behavior change tactic, extinction provides zero probability of reinforcement. As a behavioral process, extinction refers to the diminishing rate of a previously reinforced behavior when that behavior no longer produces reinforcement. As a principle, extinction refers to the functional relation between withholding reinforcement for a previously reinforced behavior and the resultant diminishing rate of response.

Practitioners have used extinction effectively in a wide variety of settings with problem behaviors ranging from mild disruptions to aggressive and self-injurious behavior. The effectiveness of extinction depends primarily on identifying and consistently withholding the reinforcer maintaining the target behavior. Although executing an extinction procedure would appear simple, implementing it effectively in applied settings can be difficult. This chapter describes three function-based extinction tactics, addresses common misuses of the term extinction, identifies secondary effects of extinction, and explains variables affecting resistance to extinction. The chapter concludes with guidelines for using extinction effectively and a discussion of when not to use extinction as a sole behavior reduction tactic.

EXTINCTION DEFINED

Extinction as a behavior change tactic occurs when reinforcement of a previously reinforced behavior is discontinued; as a result, the occurrence of that behavior decreases in the future.[1] Keller and Schoenfeld (1950) defined extinction this way: "Conditioned operants are extinguished by severing the relation between the act and the effect. . . . The principle of Type R [operant] extinction may be put as follows: The strength of a conditioned operant may be diminished by withholding its

reinforcement" (pp. 70–71). Similarly, Skinner (1953) wrote, "When reinforcement is no longer forthcoming, a response becomes less and less frequent in what is called 'operant extinction.'" (p. 69).

Note that an extinction procedure does not prevent the target behavior from occurring. Rather, extinction terminates the response–reinforcer relation by changing the environment so that the behavior no longer produces reinforcement.

When the third-grade teacher instructed the class to begin a written exercise, Moira frequently shouted, jumped out of her seat, and knocked her materials to the floor. Moira's teacher would ask her to calm down, tell her to return to her seat, explain patiently why her outbursts distracted her classmates, describe how she should behave, and offer to let Moira do another task. Moira would smile and agree to behave appropriately, but her annoying disruptions persisted. Suspecting that Moira disrupted the class to get his attention, the teacher decided he would offer Moira an alternative activity, but he would no longer ask her to calm down, tell her to return to her seat, explain matters, or describe better behavior. After 4 days, during which her disruptions produced no teacher attention, or attention from her classmates, Moira's disruptions decreased to zero.

Procedural and Functional Forms of Extinction

Vollmer and Athens (2011) noted, "There appears to have been a strong presumption in the early applied behavior analysis literature that problem behavior is always maintained by attention" (p. 319). As a result, many behavior analysts and practitioners relied on a procedural form of extinction (i.e., just ignore it, and it will go away) as treatment for problem behavior. Procedural extinction was used in the previous classroom example. The teacher suspected that Moira disrupted the class to get his attention and began ignoring her disruptions. In this scenario, Moira's problem behavior was maintained by positive reinforcement in the form of contingent teacher attention (e.g., explaining why the outbursts distracted classmates, describing how she should behave), and when the teacher consistently withheld that attention, the disruptions decreased. However, simply defaulting to "ignore it" as a method for applying extinction may not withhold the reinforcer maintaining the problem behavior.

Current best practice for treating problem behavior begins with an assessment to determine the behavior's function for the client (see Chapter 27). If extinction is indicated as a treatment option, its form is then matched to the function of the problem behavior. Had a functional assessment shown that Moira's disruptive behavior was maintained by socially mediated attention, her teacher's withholding attention following disruptions (i.e., not asking her to calm down and return to her seat, not explaining why her disruptions distracted the class, and not describing how she should behave) would have constituted a function-based application of extinction.

If a functional assessment revealed that Moira's outbursts were maintained by escape from instructional demands (i.e., negative reinforcement), teacher attention would not have constituted an extinction condition and most likely would have been ineffective. Extinction for negatively reinforced behavior requires the discontinuation of escape or avoidance from the stimulus conditions that evoke the behavior. In this case, Moira's disruptions would no longer enable her to avoid the workbook exercise in favor of a preferred activity.

The clarification between procedural and functional variations of extinction has led to more effective treatments (Lerman & Iwata, 1996a). When the form of extinction matches the function of the problem behavior, the intervention is usually effective (Vollmer & Athens, 2011). Detailed procedures for implementing function-based extinction are described later in this chapter.

Extinction: Misuses of a Technical Term

With the possible exception of *negative reinforcement, extinction* is the most misunderstood and misused technical term in applied behavior analysis. As a technical matter, *extinction* should be used only to identify (a) withholding the reinforcer for a previously reinforced behavior (the procedure), (b) a decreasing response rate under an extinction procedure (the process), or (c) the functional relation between withholding reinforcement for a previously reinforced behavior and the resultant diminishing rate of response (the principle). Four common misuses of extinction terminology are described in this section.

Using Extinction to Refer to Any Decrease in Behavior

A common error is using *extinction* to refer to any decrease in responding. Describing decreased responding that is due to any behavior change tactic or principle other than extinction (e.g., an abolishing operation, punishment, reinforcement for an alternative behavior) with a statement such as "the behavior is extinguishing" is conceptually and technically incorrect. Another common error is saying "the behavior extinguished" in reference to any reduction in behavior that reaches a zero count of occurrence.

Confusing Forgetting and Extinction

A misuse of the term *extinction* occurs when the speaker confuses extinction with forgetting. In forgetting, a behavior is weakened by the passage of time during which the person has no opportunity to emit the behavior. In extinction, behavior is weakened because it does not produce reinforcement.

Confusing Response Blocking and Sensory Extinction.

Applied behavior analysts have used objects such as goggles, gloves, helmets, and wrist weights to mask the automatic positive reinforcement received from sensory stimulation during sensory extinction. The applications of response blocking to reduce problem behaviors appear similar to sensory extinction. Response blocking, however, is not an extinction procedure. With all extinction procedures, including sensory consequences, the persons can emit the problem behavior, but that behavior will not produce reinforcement. By contrast, response blocking prevents the occurrence of the target behavior (Vollmer & Athens, 2011).

Confusing Noncontingent Reinforcement and Extinction

Noncontingent reinforcement (NCR) is another tactic for decreasing behavior that is sometimes confused with extinction.

With NCR, stimuli with known reinforcing properties are delivered on a fixed-time or variable-time schedule independent of responding (see Chapter 26). NCR does not entail withholding the reinforcer that maintains the problem behavior.

NCR is an important and effective intervention for diminishing problem behavior, but NCR operates on behavior in a different way than does extinction. Although both procedures produce a decrease in behavior, the behavioral effects result from different controlling variables. Extinction diminishes behavior by eliminating the reinforcing consequence; NCR diminishes behavior by creating an abolishing operation (see Chapter 16).

Misusing extinction terminology may be more harmful than a conceptual or technical language error. Such mistakes can lead to erroneous assumptions and faulty treatment decisions. Box 24.1: "Extinction Semantics" provides examples of correct, incorrect, and questionable statements inferring extinction with respect to treatments intended to decrease behavior, observed effects, and the principles responsible for the behavior change.

EXTINCTION PROCEDURES

Specifically, extinction procedures take three distinct forms that are linked to behavior maintained by positive reinforcement,[2] negative reinforcement, and automatic reinforcement.

Extinction of Behavior Maintained by Positive Reinforcement

Behaviors maintained by positive reinforcement are placed on extinction when those behaviors do not produce the reinforcer. In a classic extinction study, Williams (1959) described the effects of removing positive reinforcement on the tyrant-like behavior of a 21-month-old boy. The child had been seriously ill

BOX 24.1

Extinction Semantics

Statement	Meaning
We used *extinction* to treat Yoshiaki's inappropriate call-outs.	Refers to extinction as a *behavior change procedure*. The statement is correct if the procedure withheld the previous sources of reinforcement for Yoshiaki's call-outs. The statement is incorrect if the procedure withheld presumed sources of reinforcement for Yoshiaki's call-outs (e.g., "We ignored Yoshiaki's call-outs.").
Yoshiaki's call-outs are undergoing *extinction*.	Refers to extinction as a *behavioral process*. The statement is correct if describing a decreasing rate of response during a treatment condition in which previous sources of reinforcement for Yoshiaki's call-outs are withheld. The statement is incorrect if describing a decreasing rate of response during a treatment condition in which presumed sources of reinforcement for Yoshiaki's call-outs are withheld. If that is the case, the decreased rate of responding is due to other factors.
Extinction decreased Yoshiaki's call-outs.	Refers to extinction as a *principle of behavior*. The statement is correct only if an experimental analysis demonstrated a functional relation between the extinction procedure and the decreased occurrence of the behavior.
Audrey's second-language skills have *extinguished*. She has not spoken Italian since her last language class 3 years ago.	Attributing this lack of behavior to extinction is correct only if Audrey's attempts to speak Italian since her language class produced no reinforcement. If Audrey's Italian was weakened by the passage of time during which she had no opportunities to speak the language, then the statement confused extinction with forgetting.
Because a functional analysis suggests that Lefki's problem behavior is maintained by negative reinforcement, I recommend *escape extinction* as treatment. When you present a task to Lefki and she begins to engage in the problem behavior, physically guide her through the task, but do not let her escape from the task situation.	This statement correctly identifies escape extinction as the function-based form of extinction and describes a procedure for implementing it.
We have been *extinguishing* Jeremy's eye rubbing by blocking hand movements toward his eyes, and it's working.	This statement probably confuses response blocking with extinction. If Jeremy's eye rubbing was maintained by automatic reinforcement in the form of sensory stimulation, an extinction procedure would allow Jeremy to rub his eyes, but the responses would not produce the reinforcing stimulation.

for the first 18 months of his life but had completely recovered when the study began. The boy demanded special attention from his parents, especially at bedtime, and responded with temper tantrums (e.g., screaming, fussing, crying) when his parents did not provide the attention. A parent spent ½ to 2 hours each bedtime waiting in the bedroom until the boy went to sleep.

Although Williams did not speculate about how the tantrums developed, a likely explanation is not difficult to imagine. Because the child had been seriously ill for much of his first 18 months, crying had been his signal that he was experiencing discomfort or pain or needed help. In effect, his crying may have been reinforced by his parents' attention. Crying became a high-frequency behavior during the extended illness and continued after the child's health improved. The parents realized eventually that their child cried at bedtime to gain their attention and tried to ignore the crying. The crying increased in intensity and emotion when they did not stay in the room. As the days and weeks went by, the child's demands for attention at bedtime grew worse. The parents decided again not to stay with the child at bedtime; but the intensity of the crying increased, and some new tantrum behaviors occurred. The parents returned to the room and, by giving in to the tantrums, taught their child to behave like a tyrant.

After 3 months of the tyrant-like behavior, the parents decided they must do something about their child's tantrums. It appeared that parental attention maintained the tantrums; therefore, they planned to apply an extinction procedure. The parents, in a leisurely and relaxed manner, put the child to bed, left the bedroom, and closed the door. The parents recorded the duration of screaming and crying from the moment they closed the door.

The solid data path in Figure 24.1 shows the duration of tantrums for the 10 days following the first extinction intervention. The child had a tantrum for 45 minutes the first time he was put to bed without his parents staying in the room. The tantrums gradually decreased until the 10th session, when the child "no longer whimpered, fussed, or cried when the parents left the room. Rather, he smiled as they left. The parents reported that their child made happy sounds until he dropped off to sleep" (Williams, 1959, p. 269).

No tantrums occurred for approximately 1 week, but they resumed after his aunt put him to bed. When the child started to tantrum, the aunt returned to the bedroom and stayed with the child until he went to sleep. Tantrums then returned to the previous high level and had to be decreased a second time.

The dashed data path in Figure 24.1 during the second extinction intervention following the aunt's intervention. The data curve is similar to that of the first removal of parent attention. The duration of the tantrums was somewhat greater during the second removal, but reached zero by the ninth session. Williams reported that the child had no further bedtime tantrums during 2 years of follow-up.

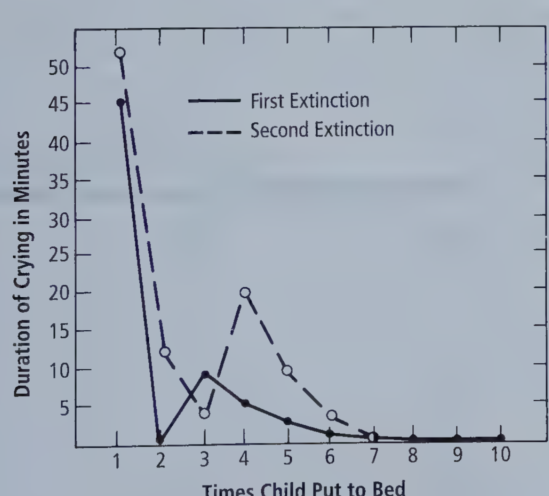

Figure 24.1 Two extinction series showing duration of crying as a function of being put to bed.

Extinction of Behavior Maintained by Negative Reinforcement

Behaviors maintained by negative reinforcement are placed on extinction (also called **escape extinction**) when those behaviors do not produce a removal of the aversive stimulus, meaning that the person cannot escape from the aversive situation.

Anderson and Long (2002) provided treatment to reduce the problem behaviors of Drew, an 8-year-old boy with autism and moderate to severe intellectual disabilities. Drew's problem behaviors consisted of self-injurious behavior aggression, and disruptions. Results of a functional behavior assessment led Anderson and Long to hypothesize that escape from task situations maintained the problem behaviors. Based on this hypothesis, the speech therapist used escape extinction to diminish the problem behaviors that occurred while Drew worked on match-to-sample and receptive language tasks (these tasks evoked the highest rates of problem behavior). The speech therapist provided instructional prompts during the tasks. When Drew emitted problem behaviors following the instructional prompt, the speech therapist physically guided him to complete the task. Escape extinction produced a significant reduction in problem behaviors during the match-to-sample and receptive language tasks. Figure 24.2 shows the number of problem behaviors emitted per minute during baseline (i.e., escape) and escape extinction conditions.

A study by Dawson and colleagues (2003) provides another excellent example of escape extinction. They used escape extinction to help Mary, a 3-year-old whose total food refusal resulted in her admission to an outpatient program for the treatment of severe behavior problems. Her medical history included gastroesophageal reflux, delayed gastric emptying, and gastrostomy tube dependence, among other medical issues. Her food refusal included head turning when presented with a bite of food, putting her hand on the spoon or therapist's hand or arm, and using her hands or bib to cover her face.

The escape extinction procedure followed 12 sessions of food refusal. If Mary refused the bite of food, the therapist held the spoon to Mary's mouth until she took the bite. When Mary expelled the bite, the food was re-presented until swallowed. With this procedure, Mary's refusals did not produce an escape from the food. The therapist terminated the session after Mary

had swallowed 12 bites of food. Mary accepted no food during the 12 baseline sessions; but after 2 sessions of escape extinction, Mary's food acceptance increased to 100% compliance.

Extinction of Behavior Maintained by Automatic Reinforcement

Some behaviors produce natural sensory consequences that reinforce the behaviors that produce them. Rincover (1981) described a naturally occurring sensory reinforcer as a stimulus that "sounds good, looks good, tastes good, smells good, feels good to the touch, or the movement itself is good" (p. 1). Behaviors maintained by automatic positive reinforcement are placed on extinction (also called *sensory extinction*) by masking or removing the sensory consequence (Vollmer & Athens, 2011).

Automatic reinforcement can maintain self-injurious behaviors and persistent, nonpurposeful, repetitive self-stimulatory behaviors (e.g., flipping fingers, head rocking, toe walking, hair pulling, fondling body parts). Kennedy and Sousa (1995) reported that a 19-year-old man with profound disabilities had poked his eyes for 12 years, which resulted in visual impairment in both eyes. Eye poking was thought to serve a sensory stimulation function because it occurred most frequently when he was alone. When Kennedy and Sousa used goggles to mask contact with his eyes, eye-poking behavior decreased markedly.

Deaver, Miltenberger, and Stricker (2001) used extinction to decrease hair twirling. Hair twirling is a frequent precursor to hair pulling, a serious self-injury. Tina, at 2 years and 5 months of age, received treatment for hair twirling and pulling. A functional analysis documented that Tina did not twirl or pull hair to obtain attention, and that hair twirling most often occurred when Tina was alone at bedtime. The sensory extinction procedure consisted of Tina wearing thin cotton mittens on both hands at naptime during day care and during bedtime at home. Figure 24.3 shows that sensory extinction diminished hair twirling to near zero levels at home and at day care.

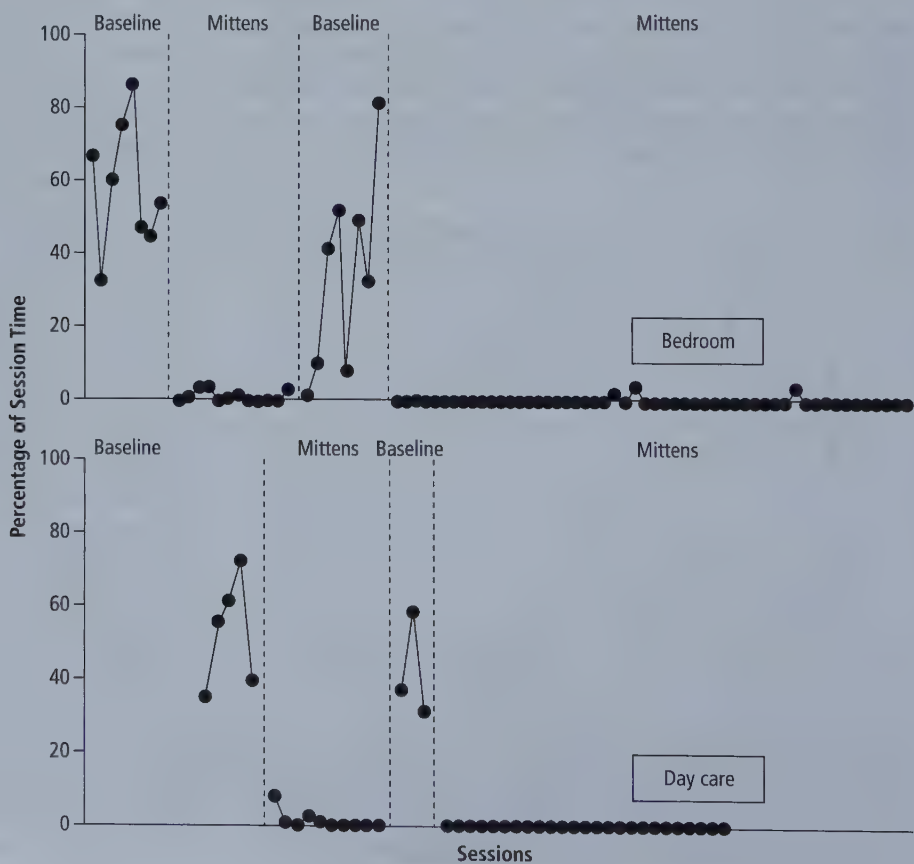

Figure 24.3 The percentage of session time of hair twirling during baseline and treatment conditions in the home and day-care settings.

Rincover, Cook, Peoples, and Packard (1979) and Rincover (1981) provided the following examples of applying extinction with automatic reinforcement:

1. A child persisted in flipping a light switch on and off. The visual sensory consequence was removed by disconnecting the switch.
2. A child persistently scratched his body until it bled. The tactile (touch) sensory consequence was removed by putting a thin rubber glove on his hand so that he could not feel his skin. Later, the glove was faded by gradually cutting off portions of it.
3. A child would throw up and then eat the vomit. The gustatory (taste) extinction procedure consisted of adding lima beans to the vomit. The child did not like lima beans; therefore, the vomit did not taste as good, and the positive sensory consequence was masked.
4. A child received kinesthetic stimulation (i.e., stimulation of muscles, tendons, and joints) by holding his arms out to his side and incessantly flapping his fingers, wrists, and arms. The extinction procedure consisted of taping a small vibratory mechanism on the back of his hand to mask the kinesthetic stimulation.
5. A child produced auditory stimulation by persistently twirling an object, such as a plate, on a table. Carpeting the surface of the table he used for spinning objects masked the auditory stimulation from his plate spinning.

SECONDARY EFFECTS OF EXTINCTION

When a previously reinforced behavior is emitted but not followed by the usual reinforcing consequences, the occurrence of that behavior will decrease to its pre-reinforcement level or stop entirely. However, numerous unreinforced responses can occur during an extinction procedure. The decrease in rate of response during extinction tends to be sporadic, with a gradual increase in pauses between responses.

In addition to extinction's primary effect of decreasing response rate, behaviors undergoing extinction often show other predictable characteristic effects, which can make the extinction procedure difficult for practitioners to apply: (a) extinction burst, (b) response variation, (c) initial increase in response magnitude, (d) spontaneous recovery, (e) resurgence, and (f) emotional outbursts and aggression. (Lattal, St. Peter Pipkin, & Escobar, 2013; Lerman & Iwata, 1995, 1996a; Murphy & Lupfer, 2014; Vollmer & Athens, 2011). These extinction effects have strong generality across species, response classes, and settings. Although applied behavior analysts almost always apply extinction as part of a treatment package that includes components that limit or prevent these extinction effects, practitioners must be aware of environmental conditions and competing contingencies that may exacerbate unwanted effects.

Extinction Burst

A common effect of the extinction procedure is an immediate increase in the rate of the response after removing the positive, negative, or automatic reinforcement. The behavioral literature uses the term **extinction burst** to identify this initial increase in rate of response. Figure 24.4 presents an illustration of an extinction burst. Operationally, Lerman, Iwata, and Wallace (1999) defined extinction burst as "an increase in responding during any of the first three treatment sessions above that observed during all of the last five baseline sessions or all of baseline" (p. 3). The extinction burst is well documented in basic research, but not well documented in applied research (Lerman & Iwata, 1995, 1996a). When reported, the bursts have occurred for only a few sessions without notable problems.

Goh and Iwata (1994) provided data showing an extinction burst. Steve was a 40-year-old man with profound developmental disabilities. He had been referred for evaluation for self-injury (head banging, head hitting). A functional analysis showed that self-injury was reinforced by escape from instructions. Goh and Iwata used extinction for the treatment of Steve's self-injury. The top panel in Figure 24.5 shows extinction bursts occurring with the onset of each of the two extinction phases.

Problem behaviors can worsen during extinction before they show improvement. For example, practitioners should anticipate an initial increase in disruption during extinction.

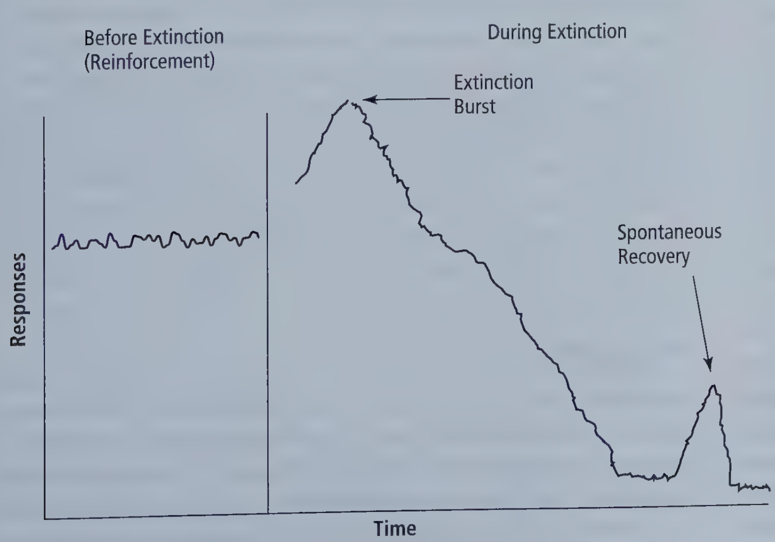

Figure 24.4 Hypothetical data illustrating an extinction burst and spontaneous recovery.

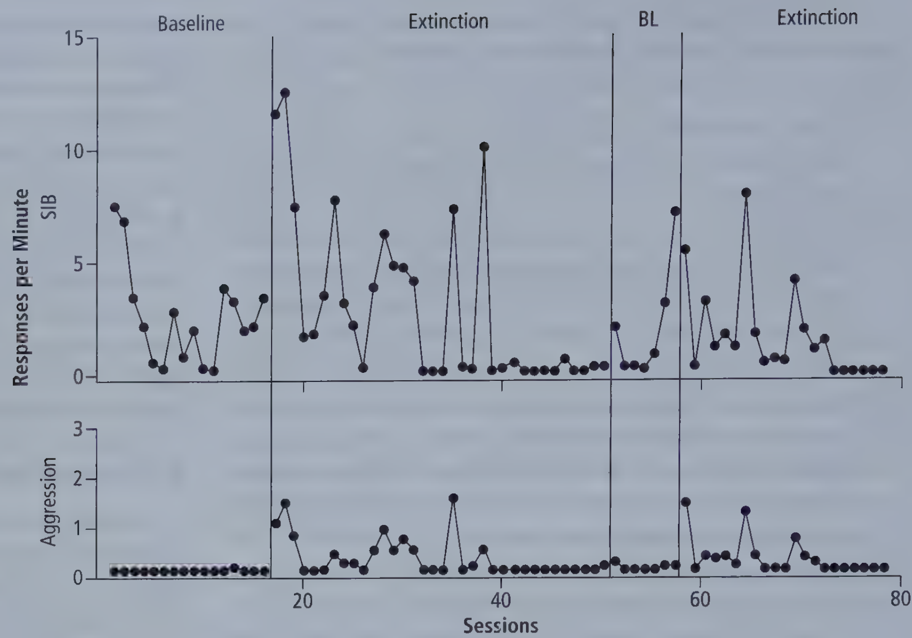

Figure 24.5 Number of responses per minute of self-injurious behavior (SIB) (top panel) and aggression (bottom panel) for Steve during baseline and extinction.

"Behavioral Persistence and Variability during Extinction of Self-Injury Maintained by Escape", by H.-L. Goh and B. A. Iwata, 1994, Reproduced with permission of John Wiley & Sons Inc.

Thereafter, problem behaviors should begin to decrease and should return to their pre-reinforcement level. Applied behavior analysts need to anticipate extinction bursts and be prepared to consistently withhold the reinforcing consequence. Extinction bursts usually suggest that the reinforcer (or reinforcers) maintaining the problem behavior was (or were) successfully identified, indicating that there is a good chance of an effective intervention.

Response Variation

Diverse and novel forms of behavior are sometimes observed during the extinction process (Kinloch, Foster, & McEwan, 2009; Peleg, Martin, & Holth, 2017). Commenting on this **extinction-induced variability**, Vollmer and Athens (2011) noted:

> From a layperson's perspective, it appears that the individual is "trying" to find new or at least other ways of obtaining reinforcement. For example, if a child asks politely for a reinforcer and the request is denied, he or she may begin to whine or attempt to "steal" the item. (p. 323)

Vollmer and Athens (2011) also raised an important consideration for applied behavior analysts. Although novel behaviors induced by extinction are often undesirable (e.g., whining, stealing, hitting), other novel behaviors can be desirable and appropriate. The behavior analyst can reinforce the appropriate novel behavior as an alternative behavior.

Initial Increase in Response Magnitude

An increase in response magnitude also may occur during the early stages of extinction. Parents who begin to ignore a child's bedtime tantrums might experience an increase in the loudness of screaming and the force of kicking before the tantrums begin to diminish. The extinction procedure is often difficult for teachers and parents to apply if there is an initial increase in response magnitude. For example, parents may be unwilling to ignore tantrum behavior for a sufficient amount of time because tantrums are aversive to parents and disruptive to other family members or siblings trying to go to sleep. Rolider and Van Houten (1984) presented a tactic for this practical problem. They suggested teaching parents to ignore gradually increasing durations of bedtime crying. They used baseline data to assess how long the parents could ignore bedtime crying comfortably before attending to their child. Then, the parents gradually increased their duration of ignoring. Every 2 days they waited an additional 5 minutes before attending to the child until a sufficient total duration of time was achieved.

Spontaneous Recovery

A behavior will typically continue a decreasing trend during extinction until it reaches a pre-reinforced level or ultimately ceases. However, a phenomenon commonly associated with the extinction process is the reappearance of the behavior after it has diminished to its pre-reinforcement level or stopped entirely. Basic researchers commonly report this extinction effect and call it **spontaneous recovery** (Rescorla, 2004). With spontaneous recovery, the behavior that diminished during the extinction process recurs even though the behavior does not produce reinforcement. Spontaneous recovery is short-lived and limited if the extinction procedure remains in effect (see Figure 24.4). Therapists and teachers need to know about spontaneous recovery, or they might conclude erroneously that the extinction procedure is no longer effective.

Resurgence

As Winterbauer, Lucke, and Bouton (2013) state: "An operant behavior that has undergone extinction can return ('resurge') when a second operant that has replaced it itself undergoes extinction" (p. 60). **Resurgence** refers to the reoccurrence of a previously reinforced behavior when reinforcement for an

alternative behavior is terminated or decreased and to the three-phase procedure that produces the effect: (1) A target behavior is reinforced, (2) the target behavior is placed on extinction and reinforcement provided for an alternative behavior, and (3) both responses are placed on extinction (Lattal & St. Peter Pipkin, 2009; Lieving & Lattal, 2003). During the final phase, the previously reinforced target behavior re-emerges, even though it remains under extinction condition.

The three-phase resurgence sequence might play out in an applied scenario as follows. (1) A student's rude remarks to other children on the playground produce reinforcement in the form of teacher attention. (2) The teachers supervising recess ignore the rude remarks (i.e., place the problem behavior on extinction) and attend to and praise all instances of appropriate interactions by the student (i.e., reinforce an alternative behavior). The intervention of extinction plus differential reinforcement of alternative behavior produces the desired effect: Occurrences of the student's inappropriate playground behavior decrease to zero and appropriate interactions increase. (3) Believing they have solved the problem, the teachers provide less and less attention to the alternative behavior. The resurgence of rude remarks by the student surprises the teachers.

Resurgence is not necessarily a negative phenomenon. Desirable resurgence occurs when a previously reinforced adaptive behavior recurs following an extinction period and during a period when other behaviors in the repertoire are unsuccessful (Epstein, 1991; Hoffman & Falcomata, 2014). Lattal and St. Peter Pipkin (2009) described a scenario in which the desirable resurgence of appropriate academic behavior might occur.

> Consider a situation in which a student taking an examination suddenly remembers information related to a topic. This could develop as follows. Assume that a teacher praises the use of a particular strategy to solve problems (similar to the reinforcement phase), but that this strategy is unsuccessful during subsequent lessons that involve structurally different problems (similar to the alternative reinforcement phase). With neither response now reinforced (extinction; for example, during the examination, when immediate praise would not be available for engaging in either response), the previously effective strategy may resurge. (pp. 255–256)

Although resurgence is often temporary, especially if those responses are not reinforced and some instances of the alternative behavior contact reinforcement (Wacker et al., 2010), it can also be a robust effect (Winterbauer et al., 2013). Basic and translational research has identified numerous factors that impact resurgence, including the target behavior's original reinforcement history prior to extinction (Winterbauer & Bouton, 2010), schedules of reinforcement for the alternative behavior (Winterbauer & Bouton, 2012), reinforcing the alternative behavior in a different context from that in which the problem behavior had previously been reinforced (Mace et al., 2010), reinforcing multiple alternative behaviors (Bloom & Lambert, 2015), response effort (Wilson, Glassford, & Koerkenmeier, 2016), the presence of discriminative stimuli during the resurgence test (King & Hayes, 2016), and lapses in treatment integrity (Fuhrman, Fisher, & Greer, 2016). To learn more about resurgence and its relevance for applied behavior analysts, see Lattal and St. Peter Pipkin (2009), St. Peter Pipkin (2015), and Kestner and Peterson (2017).

Emotional Outbursts and Aggression

Placing a behavior on extinction may occasion an increase in intensity or force of the response, and may evoke other emotional or aggressive behaviors (Vollmer & Athens, 2011). Common emotional outbursts and aggressive behaviors include escape, rage, prolonged whining, and crying. Other examples for the emotional outbursts and aggression may include behaviors such as escape behavior, rage, and crying.

VARIABLES AFFECTING RESISTANCE TO EXTINCTION

Behavior analysts refer to continued responding during an extinction procedure as **resistance to extinction**. Resistance to extinction is a relative concept. Behavior that continues to occur during extinction is said to have greater resistance to extinction than behavior that diminishes quickly. Three measures of resistance to extinction appear in the behavior analysis literature: (a) declining rate of response, (b) total count of responses emitted before responding ceases or attains some final low level, and (c) duration of time required for the behavior to reach a predetermined criterion (Lerman, Iwata, Shore, & Kahng, 1996; Reynolds, 1968).

Continuous and Intermittent Reinforcement

Continuous and intermittent schedules of reinforcement and their effects are described in Chapter 13. We can make three tentative statements about resistance to extinction as it relates to continuous and intermittent reinforcement. (a) Intermittent reinforcement (INT) may produce behavior with greater resistance to extinction than behavior previously reinforced by continuous reinforcement (CRF) (Keller & Schoenfeld, 1950). (b) Some intermittent schedules may produce more persistent responding during extinction than others (Ferster & Skinner, 1957). For example, variable schedules of reinforcement (variable ratio [VR], variable interval [VI]) may yield behavior more resistant to extinction than fixed schedules (fixed ratio [FR], fixed interval [FI]). (c) To a degree, the thinner the schedule of reinforcement, the greater the resistance to extinction.

Applied behavior analysts and practitioners should consider these statements as tentative guidelines, as researchers continue to discover schedule factors that influence extinction behavior. For example, recent density of reinforcement may predict continued responding during extinction (e.g., Lerman et al., 1996; Mace et al., 2011). MacDonald, Ahearn, Parry-Cruwys, and Bancroft (2013) found that four boys with autism persisted in problem behavior more so in 5-min extinction sessions that followed CRF than in extinction sessions immediately following INT reinforcement. Lerman et al. (1996) found that extinction bursts were more likely following CRF than INT.

Motivating Operations

All stimuli that function as reinforcers require a minimum level of an establishing operation (i.e., motivation must be present; see Chapter 16). The strength of the establishing operation (EO) above the minimum level will influence resistance to extinction. Basic research has shown that "resistance to extinction is greater when extinction is carried out under high motivation than under low" (Keller & Schoenfeld, 1950, p. 75).

Number, Magnitude, and Quality of Reinforcement

The number of times a behavior has produced reinforcement may influence resistance to extinction. A behavior with a long history of reinforcement may have more resistance to extinction than a behavior with a shorter history of reinforcement. If bedtime tantrums have produced reinforcement for 1 year, they might have more resistance to extinction than tantrums that have produced reinforcement for 1 week. Also, the magnitude and quality of a reinforcer will likely influence resistance to extinction. A reinforcer of greater magnitude and quality might produce more resistance to extinction than a reinforcer with less magnitude and quality.

Number of Previous Extinction Trials

Successive applications of conditioning and extinction may influence resistance to extinction. Sometimes problem behaviors diminish during extinction and then are accidentally strengthened with reinforcement. When this happens, applied behavior analysts can reapply the extinction procedure. Typically, behavior diminishes with fewer total responses during a reapplication of extinction. This effect is additive when the participant can discriminate the onset of extinction. With each successive application of extinction, decreases in behavior become increasingly rapid until only a single response occurs following the withdrawal of reinforcement.

Response Effort

Applied researchers have produced data on response effort and its effect on resistance to extinction (e.g., Lerman & Iwata, 1996a; Wilson et al., 2016). The effort required for a response apparently influences its resistance to extinction. A response requiring greater effort diminishes more quickly during extinction than a response requiring less effort.

USING EXTINCTION EFFECTIVELY

Numerous guidelines for using extinction effectively have been published, with most authors providing similar recommendations. Presented below are nine guidelines for the successful implementation of extinction.

Withhold All Reinforcers Maintaining the Problem Behavior

A first step in using extinction effectively is to identify and withhold all sources of reinforcement for the target behavior. The effectiveness of extinction depends on the correct identification of the consequences that maintain the problem behavior. Functional behavior assessments have improved greatly the application and effectiveness of using extinction in applied settings (Vollmer & Athens, 2011; Chapter 27).

Applied behavior analysts collect data on antecedent and consequent stimuli that are temporally related to the problem behavior and provide answers to questions such as the following:

1. Does the problem behavior occur more frequently when something happens in the environment to occasion the behavior (e.g., a demand or request)?
2. Is the frequency of the problem behavior unrelated to antecedent stimuli and social consequences?
3. Does the problem behavior occur more frequently when it produces attention from other persons?

If the answer to the first question is yes, the problem behavior may be maintained by negative reinforcement. If the answer to the second question is yes, the applied behavior analyst will need to consider withholding tactile, auditory, visual, gustatory, olfactory, and kinesthetic consequences alone or in combination. If the answer to the third question is yes, the behavior may be maintained by positive reinforcement in the form of social attention.

The consequence that maintains the problem behavior appears obvious in some applied settings. In the Williams (1959) study described earlier in this chapter, parental attention appeared to be the only source of reinforcement maintaining the tyrant-like behavior at bedtime. However, behaviors are frequently maintained by multiple sources of reinforcement. The class clown's behavior might be maintained by the teacher's reaction to the disruptive behavior, by attention from peers, or by a combination of both. When Johnny's parent brings him to preschool, he might cry to escape from preschool, to keep his parents with him, to occasion his teacher's concern and attention, or to achieve some combination of all three. When multiple sources of reinforcement maintain problem behavior, identifying and withholding one source of reinforcement may have minimal or no effect on behavior. If teacher and peer attention maintain inappropriate classroom behavior, then withholding only teacher attention may produce little change in the problem behavior. To effectively apply the extinction procedure, the teacher must withhold her attention and reinforce the other students in the room when they ignore their classmate's clownish behavior.

Withhold Reinforcement Consistently

When the reinforcing consequences have been identified, teachers must withhold them consistently. All behavior change procedures require consistent application, but consistency is essential for extinction; otherwise, the behavior may inadvertently be placed on an intermittent schedule of reinforcement, thereby making it more resistant to extinction. Teachers, parents, therapists, and applied behavior analysts often report

that consistency is the single most difficult aspect in using extinction. The error of not withholding reinforcement consistently negates the effectiveness of the extinction procedure, and this point cannot be overemphasized.

Combine Extinction with Other Procedures

Although extinction can be an effective singular intervention, it is rarely recommended as such (Vollmer & Athens, 2011; Vollmer et al., 1998). We also recommend that applied behavior analysts always consider combining extinction with other treatments, especially the reinforcement of alternative behaviors. Two reasons support this recommendation. First, the effectiveness of extinction may increase when it is combined with other procedures, especially positive reinforcement. By combining extinction with differential reinforcement of appropriate behaviors, for example, the applied behavior analyst alters the environment by reinforcing appropriate alternative behaviors and placing problem behaviors on extinction. During intervention, the extinction procedure should not reduce the overall number of positive consequences received by a participant. Second, differential reinforcement and antecedent procedures may reduce extinction bursts and aggression (Lerman et al., 1999).

Rehfeldt and Chambers (2003) combined extinction with differential reinforcement for the treatment of verbal perseveration maintained by positive reinforcement in the form of social attention. The participant was an adult with autism. Rehfeldt and Chambers presented social attention contingent on appropriate and non-perseveration speech, and applied attention extinction by not responding to the participant's inappropriate verbal behavior. This combined treatment produced an increase in appropriate verbal responses and a decrease in perseveration. These data suggest that contingencies of reinforcement might maintain the unusual speech of some individuals with autism.

The bedtime pass developed by Friman et al. (1999) as treatment for pediatric resistance to bedtime is another example of an intervention combining extinction with reinforcement for appropriate alternative behavior. Upon being put to bed, the child is given a small notecard exchangeable for one brief trip out of the bedroom for specific activity (e.g., use the bathroom, one more hug from Mom or Dad). The parents then return the child to bed without comment and ignore any further crying or calling out. In a systematic replication of the bedtime pass with four 3-year-olds, Freeman (2006) reported the intervention eliminated bedtime resistance without producing extinction bursts.

Use Instructions

Contingencies of reinforcement affect the future frequency of behavior automatically. It is not necessary for people to know, to describe, or even to perceive that contingencies are affecting their behavior. However, behaviors sometime diminish more quickly during extinction when practitioners describe the extinction procedure to clients. For example, teachers frequently provide small-group instruction while other students do independent seatwork. When seatwork students ask questions, they interrupt instruction. Many teachers correct this problem by placing question asking on extinction. They simply ignore student questions until after the end of small-group instruction. This tactic is often effective. The extinction procedure, however, tends to be more effective when teachers inform the class that they will ignore all student questions until after the end of small-group instruction.

Plan for Extinction-produced Aggression

Behaviors that occurred infrequently in the past may become more prominent during extinction. These extinction-produced behaviors are often emotional and aggressive (Lerman et al., 1999; Vollmer & Athens, 2011). Skinner (1953) interpreted the change in response topographies (e.g., side effects) as emotional behaviors, including the aggression that sometimes accompanies extinction.

Goh and Iwata (1994) provided a convincing demonstration showing how aggression-induced behaviors occurred when a target behavior was placed on extinction. Steve was a 40-year-old man with profound intellectual disabilities. He had been referred for evaluation for self-injury (head banging, head hitting). A functional analysis showed that self-injury was reinforced by escape from instructions. Goh and Iwata used extinction for the treatment of Steve's self-injury. Steve rarely slapped or kicked other persons (i.e., aggression) during the two baseline phases, but aggression increased with the onset of the two extinction phases (see Figure 24.5, bottom panel). Aggression essentially stopped by the end of each extinction phase when self-injury was stable and low, even though Steve's aggression remained untreated during the baseline and extinction conditions.

Applied behavior analysts need to manage aggressive behaviors when they occur as side effects of extinction. It is critical that extinction-produced aggression not produce reinforcement. Frequently, parents, teachers, and therapists react to the aggression with attention that may function as reinforcement of the extinction-produced aggression. For instance, a teacher decides to ignore Moira's questions while providing small-group instruction. When Moira interrupts the teacher with a question, the teacher does not respond. Moira then starts disrupting other seatwork students. To quiet Moira down, the teacher responds, "Oh, all right, Moira, what did you want to know?" In effect, the teacher's behavior may have reinforced Moira's interruptions during small-group instruction and the accompanying inappropriate disruptions of the other seatwork students.

At times, extinction-produced aggression takes the form of verbal abuse. Often, teachers and parents do not need to react to it. If extinction-produced aggression results in reinforcement, individuals simply use other inappropriate behavior, such as verbal abuse, to produce reinforcement. However, teachers and parents cannot and should not ignore some forms of aggression and self-injurious behavior. They need to know (a) that they can ignore some aggression, (b) when they need to intervene on the aggression, and (c) what they will do for the intervention.

Increase the Number of Extinction Trials

An extinction trial occurs each time the behavior does not produce reinforcement. Whenever possible, applied behavior analysts should increase the number of extinction trials for the problem behaviors. Increasing the number of trials improves efficiency by accelerating the extinction process (i.e., the cumulative series of instances in which the behavior–controlling variable–primary effect sequence occurs). Applied behavior analysts can increase extinction trials when increased occurrences of the problem behavior can be tolerated during intervention. For example, Keith's parents used an extinction procedure to reduce his tantrums. His parents noticed that Keith had tantrums most often when he did not get his way about staying up late, eating a snack, and going outside. For the purpose of the program, they decided to set up several additional situations each day in which Keith did not get his way. Keith was then more likely to emit the inappropriate behavior more often, thereby giving his parents more occasions to ignore it. As a result, his tantrums decreased in a shorter period than they would have if left at their usual occurrence.

Include Significant Others in Extinction

It is important that other persons in the environment not reinforce undesirable behavior. A teacher, for example, needs to share extinction plans with other people who might help in the classroom—parent volunteers, grandparents, music teachers, speech therapists, industrial arts specialists—to avoid their reinforcing inappropriate behaviors. For extinction to be maximally effective, meaning having few, if any, instances of extinction bursts, significant increases in response magnitude, and so forth, all persons in contact with the learner must withhold reinforcement for the problem behavior.

Maintain Extinction-decreased Behavior

Applied behavior analysts leave the extinction procedure in effect permanently for maintaining the extinction-diminished behavior. A permanent application of escape extinction and attention extinction is a preferred procedure. Applied behavior analysts can use a permanent application also with some sensory extinction procedures. For example, the carpeting on a table used for spinning objects could remain in place indefinitely. Some applications of sensory extinction appear inappropriate and inconvenient if kept permanently in effect. For example, requiring Tina to permanently wear thin cotton mittens on both hands at naptime during day care and during bedtime at home appears inappropriate and inconvenient (see Figure 24.3). In such a case, the applied behavior analyst can maintain treatment gains by gradually fading out the sensory extinction procedure—for example, cutting off 1 inch of the glove palm every 3 to 4 days until the glove palm is removed. The analyst may then remove the fingers and thumb one at a time to gradually remove the mittens.

Guard Against Unintentional Extinction

Desirable behaviors are often unintentionally placed on extinction. A beginning teacher confronted with one student who is on task and many other students who are not will probably direct most of his attention to the majority and will provide little or no attention to the student who is working. It is common practice to give the most attention to problems ("the squeaky wheel gets the grease") and to ignore situations that are going smoothly. However, behaviors must continue to be reinforced if they are to be maintained. Teachers must be vigilant to "catch them being good" and deliver reinforcement accordingly.

WHEN NOT TO USE EXTINCTION

Although most interventions designed to decrease behavior will include withholding reinforcement for the target behavior, we envision at least four circumstances when applied behavior analysts should not use extinction as a singular intervention.

The Behavior Is Harmful

Some behaviors are so self-injurious, harmful to others, or destructive to property that they must be controlled with the most rapid and humane procedure available. Extinction as a singular intervention is not recommended in such situations.

All Sources of Reinforcement Cannot Be Withheld

Practitioners and significant others may discontinue reinforcement for previously reinforced behavior at every instance. If, however, the target behavior contacts other sources of reinforcement, the extinction procedure is doomed at the outset. A classic case in point is the previous scenario of the class clown obtaining attention from classmates while his teacher dutifully ignores his antics.

A Rapid Reduction in Response Rate Is Required

Practitioners often do not have the luxury of time to change behavior gradually. A vocational student who talks back to supervisors on a community job site may get fired before an intervention relying on extinction eliminates the problem behavior.

Others Are Likely to Imitate the Problem Behavior

Some behaviors can be tolerated if only one person emits them for a while. Those same behaviors may be intolerable if several persons begin emitting them. An extinction-only intervention is ill advised if others are likely to imitate the behavior placed on extinction ("Hey, if Thad can toss papers, turn over desks, or scream expletives, so can we!").

SUMMARY

Extinction Defined

1. Withholding reinforcement for a previously reinforced behavior decreases the rate of that behavior: a procedure, process, and principle known as *extinction*.
   - As a behavior change procedure, extinction provides zero probability of reinforcement.
   - As a behavioral process, extinction refers to the diminishing rate of a previously reinforced behavior when that behavior no longer produces reinforcement.
   - As a principle, extinction refers to the functional relation between withholding reinforcement for a previously reinforced behavior and the resultant diminishing rate of response.
2. Functional behavior assessments (see Chapter 27) enable behavior analysts to distinguish clearly between the procedural variations of extinction (i.e., most commonly—"Just ignore it, and it will go away."), and the functional variations of extinction (i.e., identifying the specific reinforcer maintaining the behavior).
3. Behavior analysts should use *extinction* only to identify (a) withholding the reinforcer for a previously reinforced behavior (the procedure), (b) a decreasing response rate under an extinction procedure (the process), or (c) the functional relation between withholding reinforcement for a previously reinforced behavior and the resultant diminishing rate of response (the principle).
4. Extinction (a) does not refer to any decrease in behavior, (b) is not the same as forgetting, (c) is not response blocking, and (d) is not noncontingent reinforcement.

Extinction Procedures

5. Procedures for extinction take three distinct forms that are linked to behavior maintained by positive reinforcement, negative reinforcement, and automatic (positive and negative) reinforcement.
6. Behaviors maintained by positive reinforcement are placed on extinction when those behaviors do not produce the reinforcer.
7. Behaviors maintained by negative reinforcement are placed on extinction (escape extinction) when those behaviors do not produce a removal of the aversive stimulus, meaning that the individual cannot escape from the aversive situation.
8. Behaviors maintained by automatic positive reinforcement are placed on extinction (sensory extinction) by masking or removing the sensory consequence.
9. Behaviors maintained by automatic negative reinforcement are placed on extinction by not removing (escape extinction) the aversive sensory stimulation.

Secondary Effects of Extinction

10. Behaviors undergoing extinction are usually associated with effects in occurrence and topography of response.
11. Common effects of extinction include (a) extinction burst, (b) response variation, (c) initial increase in response magnitude, (d) spontaneous recovery, (e) resurgence, and (f) emotional outbursts and aggression.

Variables Affecting Resistance to Extinction

12. Behavior that continues to occur during extinction is said to have greater resistance to extinction than behavior that diminishes quickly. Resistance to extinction is a relative concept.
13. Intermittent schedules of reinforcement may produce behavior with greater resistance to extinction than the resistance produced by a continuous reinforcement schedule.
14. Variable schedules of reinforcement (e.g., VR, VI) may have more resistance to extinction than fixed schedules (e.g., FR, FI).
15. To a degree, the thinner the intermittent schedule of reinforcement is, the greater the resistance to extinction will be.
16. Resistance to extinction is likely to increase with the strength of the establishing operation (EO) for the reinforcer being withheld.
17. The number, magnitude, and quality of the reinforcer may affect resistance to extinction.
18. Successive applications of conditioning and extinction may influence the resistance to extinction.
19. The response effort will likely influence resistance to extinction.

Using Extinction Effectively

20. Ten guidelines for using extinction are as follows:
    - Withhold all reinforcers maintaining the problem behavior.
    - Withhold reinforcement consistently.
    - Combine extinction with other procedures.
    - Use instructions.

- Plan for extinction-produced aggression.
- Increase the number of extinction trials.
- Include significant others in the intervention.
- Guard against unintentional extinction.
- Maintain extinction-decreased behavior.

When Not to Use Extinction

21. Extinction should not be used as a singular intervention in the following circumstances: when the target behavior is harmful, when all sources of reinforcement cannot be withheld, when a rapid reduction in behavior is required, or when others are likely to imitate the problem behavior.

KEY TERMS

escape extinction	extinction burst	sensory extinction
extinction (operant)	resistance to extinction	spontaneous recovery

MULTIPLE-CHOICE QUESTIONS

1. A procedure in which reinforcement of a previously reinforced behavior is discontinued and as a result, occurrences of that behavior decrease in the future is:
   a. Punishment
   b. Extinction
   c. Reinforcement
   d. Establishing Operation
   Hint: (See "Definition of Extinction")

2. What is the probability of reinforcement when utilizing an extinction procedure?
   a. 0%
   b. 15%
   c. 50%
   d. Variable
   Hint: (See "Definition of Extinction")

3. What form of extinction is used when the reinforcer (or reinforcers) maintaining a behavior is withheld?
   a. Procedural
   b. Functional
   c. Standard
   d. Respondent
   Hint: (See "Procedural and Functional Forms of Extinction")

4. What are the common misuses of the term extinction?
   a. Confusing forgetting and extinction
   b. Confusing response blocking and sensory extinction
   c. Confusing noncontingent reinforcement and extinction
   d. All of these
   Hint: (See "Extinction: Misuses of a Technical Term")

5. Delivering a stimulus with known reinforcing properties to an individual on a fixed time or variable time schedule independently of responding is known as which procedure?
   a. Extinction
   b. Noncontingent reinforcement (NCR)
   c. Differential reinforcement
   d. Punishment
   Hint: (See "Extinction: Misuses of a Technical Term")

6. What is the main effect of an extinction procedure?
   a. Increase in behavior
   b. No change in behavior
   c. Behavior decreases and/or stops entirely
   d. The effects are unknown
   Hint: (See: "Secondary Effects of Extinction")

7. An immediate increase in frequency and/or amplitude of the response after the removal of the maintaining reinforcer is called
   a. Extinction burst
   b. Reinforcement
   c. Noncontingent reinforcement
   d. Punishment
   Hint: (See "Extinction Burst")

8. The reappearance of a behavior after it has diminished to its pre-reinforced level and/or stopped entirely is called:
   a. Extinction burst
   b. Spontaneous recovery
   c. Differential reinforcement
   d. Procedural extinction
   Hint: (See "Spontaneous Recovery")

9. Continued responding during the extinction process is known as:
   a. Resistance to extinction
   b. Extinction burst
   c. Reinforcement
   d. Spontaneous recovery

   Hint: (See "Variables Affecting Resistance to Extinction")

10. Resistance to extinction is greater when carried out under:
    a. Low motivation
    b. High motivation
    c. No motivation
    d. None of these

    Hint: (See "Establishing Operation")

11. What suggestions did the authors give for assuring the effectiveness of extinction?
    a. Increasing the number of extinction trials
    b. Withholding all reinforcers maintaining the problem behavior
    c. Withholding reinforcement consistently
    d. Using instruction
    e. All of these

    Hint: (See "Using Extinction Effectively")

12. When is it not appropriate to utilize an extinction procedure?
    a. When inappropriate behaviors are likely to be imitated by others
    b. When behaviors are harmful to self or others
    c. Both of these
    d. None of these

    Hint: (See "When Not to Use Extinction")

ESSAY-TYPE QUESTIONS

1. Identify and briefly discuss four common misuses of the term extinction.

   Hint: (See "Extinction: Misuses of a Technical Term")

2. Compare and contrast the use of extinction with behaviors maintained by positive, negative, and automatic reinforcement.

   Hint: (See "Extinction of Behavior Maintained by Positive Reinforcement")

3. Discuss the phenomenon of spontaneous recovery.

   Hint: (See "Spontaneous Recovery")

4. Explain the effect of continuous and intermittent reinforcement on behavior's resistance to extinction.

   Hint: (See "Continuous and Intermittent Reinforcement")

5. List several behavioral examples that demonstrate how response effort influences a behavior's resistance to extinction.

   Hint: (See "Response Effort")

NOTES

1. The term *extinction* is also used with respondent conditioned reflexes (see Chapter 2). Presenting a conditioned stimulus (CS) again and again without the unconditioned stimulus until the CS no longer elicits the conditioned response is called *respondent extinction*.

2. Extinction linked to behaviors maintained by positive reinforcement is sometimes called *attention extinction*, especially in the functional behavior assessment (FBA) literature, in which reinforcement by social attention is one of the conditions or hypotheses explored by FBA.

CHAPTER 25

Differential Reinforcement

LEARNING OBJECTIVES

- Define and give examples of differential reinforcement.
- Define, give examples of, and explain how to use differential reinforcement of incompatible/alternative behavior.
- Define, give examples of, and explain how to use differential reinforcement of other behavior.
- Define, give examples of, and explain how to use differential reinforcement of low rates of behavior.

Does Love or Differential Reinforcement Open Doors?

There is a story about Queen Victoria and Prince Albert, which, although charming, has not been verified as historical fact (Strachey, 1921). Whether true or not, the story illustrates the use of differential reinforcement.

As the story goes, shortly after their marriage, Prince Albert and Queen Victoria had a quarrel. Albert walked (or stomped, depending on the telling) out of the room and locked himself in his study. Victoria ran after him and pounded on the door. "Who's there?" called Albert. "The Queen of England, and she demands to be admitted." Albert did not respond. Victoria pounded again. One version of the story has it that Victoria shouted, "I am the Queen of England, Scotland, Wales and Ireland, the Empress of India and of the entire British Commonwealth, I am the Commander-in-Chief of all the British armed forces, and I order you hereby to open this door!!!" Albert still did not respond. More furious knocking was followed by a pause. Then there was a gentle tap. "Who's there?" Albert asked. "Your wife, Albert," the Queen replied. The prince immediately opened the door.

This story is told on various Internet sites to extol the virtues of love or to make the point that it is more important to resolve conflict through nonviolent than violent means. But for behavior analysts, it is a fairly simple example of Prince Albert using good old-fashioned differential reinforcement (of alternative behavior) on the Queen's behavior, although we must assume her calmer, more solicitous behavior actually occurred more often under similar circumstances. Moreover, the immediate increase in the magnitude of her behavior (i.e., the extinction burst) suggests that such behavior had been reinforced in the past, either by Albert, or, more likely, by others.

And what about the effect of her capitulation on his behavior? When they quarreled in the future, was he more likely to storm out of the room and hole himself up in his study? We don't know, but we might predict so.

—H. D. Schlinger (2007, p. 385)

Practitioners can choose from a wide range of procedures for decreasing or eliminating problem behaviors. Although interventions based primarily on extinction or punishment are often effective, unwanted side effects may occur. Maladaptive emotional behavior and higher-than-usual rates of responding are commonly observed when a behavior with a long and consistent history of reinforcement is placed on extinction. Escape, avoidance, aggression, and other forms of undesirable counter-control may be evoked by punishment. In addition to unwanted side effects, another limitation of extinction and punishment as primary methods for reducing problem behaviors is that neither approach strengthens or teaches adaptive behaviors with which individuals can attain reinforcers. Beyond the possibility of unwanted side effects and their lack of educative value, interventions that rely on extinction alone or punishment in any of its forms raise important ethical and legal concerns. To dispel these limitations and concerns, applied behavior analysts have developed procedures that use differential reinforcement to diminish or eliminate problem behaviors.

DIFFERENTIAL REINFORCEMENT DEFINED

Differential reinforcement entails reinforcing one response class and withholding reinforcement for another response class. When used as a reductive procedure for problem behavior, differential reinforcement consists of (a) providing reinforcement contingent on a behavior other than the problem behavior or the problem behavior occurring at a reduced rate and (b) withholding reinforcement for the problem behavior.[1] Differential reinforcement can be implemented with positive reinforcement or negative reinforcement.

As Cowdery, Iwata, and Pace (1990) noted,

> differential reinforcement does not involve extended interruptions of ongoing activities (e.g., time-out), contingent removal of positive reinforcers (e.g., response cost), or presentation of aversive stimuli (e.g., punishment). These characteristics make differential reinforcement the least intrusive of all behavior interventions and probably account for its widespread popularity. (p. 497)

Three well-researched tactics for using differential reinforcement for decreasing inappropriate behavior are differential reinforcement of alternative behavior (DRA), differential reinforcement of other behavior (DRO), and differential reinforcement of low rates (DRL). This chapter defines, presents examples, and suggests guidelines for the effective use of each of these differential reinforcement procedures for decreasing problem behavior.

DIFFERENTIAL REINFORCEMENT OF ALTERNATIVE BEHAVIOR (DRA)

A practitioner using **differential reinforcement of alternative behavior (DRA)** reinforces occurrences of a desirable alternative to the problem behavior and withholds reinforcement for the problem behavior. DRA has the dual effects of strengthening the alternative behavior and weakening problem behavior (see Petscher, Rey, & Bailey, 2009 for a review). DRA can be conceptualized as a concurrent schedule of reinforcement in which two response classes receive reinforcement at different rates: (a) the alternative behavior on a dense schedule of high-quality reinforcement and (b) the problem behavior on extinction or a very lean schedule of reinforcement. Because the concurrent schedule favors the alternative behavior, the client allocates more responding to the alternative behavior and less responding to the problem behavior, as described by the matching law (Borrero et al., 2010; see Chapter 13).

Dixon, Benedict, and Larson (2001) used DRA to treat the inappropriate verbal behavior of Fernando, a 25-year-old man with moderate developmental disabilities and a psychotic disorder. Inappropriate vocalizations included utterances not related to the current context, sexually inappropriate remarks, illogical placement of words within a sentence, and "psychotic" statements (e.g., "There's a purple moose on my head named Chuckles," p. 362). The researchers defined appropriate verbal behavior as any vocal utterance that did not meet the defining characteristics of inappropriate vocalization. A functional analysis revealed that the inappropriate verbal statements were maintained by social attention.

During the DRA condition, the researchers attended to Fernando's appropriate statements with 10 seconds of comments relevant to his statements and ignored his inappropriate verbal behavior. For example, if Fernando said something about an activity he liked to do, the experimenter told him it was interesting and hoped he could do it again soon. Following an initial phase of treatment with DRA, the researchers created a comparison "baseline" condition by reversing the contingencies for the two response classes: Inappropriate vocalizations resulted in attention and appropriate verbal behavior was ignored. Data from the B-A-B-A-B design shows that the DRA intervention reduced Fernando's inappropriate verbal behavior and increased appropriate utterances (Figure 25.1).

In most published studies evaluating DRA, the alternative behavior and the problem behavior are mutually exclusive response classes whose different topographies make it impossible for the participant to emit both behaviors at the same time. In the Dixon et al. (2001) study, Fernando could not utter appropriate and inappropriate verbalizations at the same time. Similarly, a learner cannot simultaneously be in and out of his seat (Friman, 1990), politely ask "Can I have that please?" and scream (Schlichenmeyer, Dube, & Vargas-Irwin, 2015), comply with a therapist's instruction to complete a task and destroy the materials needed for the task (Ringdahl et al., 2002), or put an inedible item in a trashcan and in her mouth (Slocum, Mehrkan, Peters, & Vollmer, 2017). When DRA is implemented by reinforcing a behavior that cannot occur simultaneously with the problem behavior, the procedure is sometimes called **differential reinforcement of incompatible behavior (DRI)**.

The effectiveness of DRA does not depend upon an incompatible alternative behavior. An alternative behavior that occupies the participant when he might ordinarily engage in the problem behavior may be sufficient. Ideally, however, the alternative behavior serves a greater purpose than time filler. Adaptive activities or skills are the most beneficial alternative behaviors. For example, a classroom teacher could assign two students who frequently argue with each other to work on a class project together and reinforce cooperative behaviors associated with project development. Working together on a class project is not incompatible with arguing; the two response classes could occur together. However, the two students are likely to argue less when engaged in cooperative behaviors.

When differential reinforcement uses escape from a task or demand situation as a reinforcer, the procedure is sometimes identified as *differential negative reinforcement of alternative behavior* (DNRA) (e.g., Marcus & Vollmer, 1995; Piazza, Moses, & Fisher, 1996; Vollmer & Iwata, 1992). Applying DNRA to reduce the occurrence of a problem behavior maintained by escape from a task or demand context consists of providing negative reinforcement of the alternative behavior in the form of brief periods of escape from the task and escape extinction for the problem behavior.

With DNRA, positive reinforcement for the alternative behavior is often provided as well. For example, Lalli, Casey, and Kates (1995) allowed participants to escape from a task for

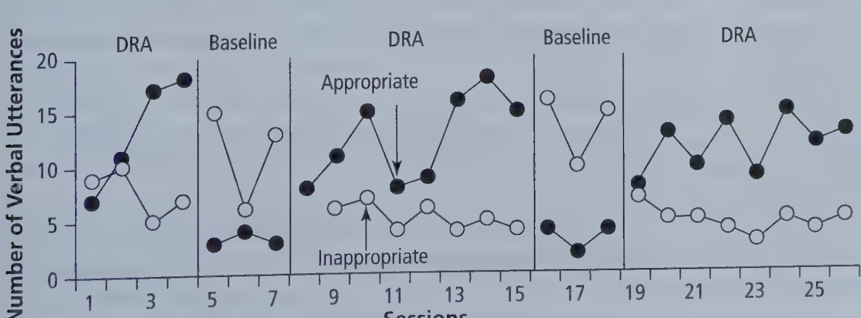

Figure 25.1 Number of appropriate and inappropriate verbal utterances by an adult male during DRA and baseline conditions.

"Functional Analysis and Treatment of Inappropriate Verbal Behavior" by M. R. Dixon, H. Benedict, & T. Larson (2001), *Journal of Applied Behavior Analysis*, *34*, p. 362. Reproduced with permission of John Wiley & Sons Inc.

30 seconds contingent on using an alternative response (e.g., giving the therapist a card with "BREAK" printed on it, or saying "no") as an alternative to their aberrant behavior. The researchers also provided praise for using the alternative responses. As training progressed, the participants' escape from a task was contingent on using the trained verbal responses and completing a gradually increasing number of required steps of the task. The DNRA intervention increased the use of the trained verbal response and decreased the problem behavior.[2]

Guidelines for Using DRA

Teachers, therapists, and parents have a long history of using DRA in education, treatment, and everyday social interactions and usually find DRA the easiest of the three differential reinforcement procedures to apply. Practitioners often use DRA as interventions for a wide range of problem behaviors. Many researchers and practitioners have discovered that the following guidelines improve the effectiveness of DRA.

Select Alternative Behavior

Ideally, the alternative behavior (a) already exists in the learner's current repertoire; (b) requires less effort, but never more, than the problem behavior; (c) occurs frequently enough to provide sufficient opportunities for reinforcement; and (d) is likely to receive reinforcement in the learner's natural environment after thinning the DRA schedule. Selecting alternative behaviors meeting these criteria will increase the initial effectiveness of DRA and facilitate the maintenance and generalization of behavior changes after terminating the intervention.

When possible, the practitioner should differentially reinforce alternative behaviors that will lead to or increase the learner's opportunity to acquire useful skills. When no behaviors meeting those criteria can be identified, the practitioner can select an alternative behavior that can be easily taught or consider using a DRO procedure as presented in the next section of this chapter. Figure 25.2 shows some examples of alternative behaviors (Webber & Scheuermann, 1991).

Select Potent Reinforcers and Deliver Them Consistently

Presenting stimulus changes that the practitioner only assumes function as reinforcement can limit or even negate the effectiveness of any reinforcement-based intervention. Providing consequences for the alternative behavior identified by stimulus preference and reinforcer assessments (see Chapter 11) and functional behavior assessments (see Chapter 27) will increase the effectiveness of DRA. In addition, reinforcers should be selected that are relevant to the motivating operations that naturally exist in the treatment setting or that can be created (e.g., by deprivation prior to treatment sessions).

The consequence that maintained the problem behavior prior to intervention is often the most effective reinforcer for the alternative behavior. Results from indirect functional assessments have been used to identify reinforcers for DRA interventions (e.g., Durand, Crimmins, Caufield, & Taylor, 1989; McDonough, Johnson, & Waters, 2017). Functional analyses are most often used to identify maintaining consequences (e.g., Athens & Vollmer, 2010; Dixon et al., 2001; Wilder, Masuda, O'Conner, & Baham, 2001).

The magnitude of the reinforcer used in a differential reinforcement intervention is probably less important than its consistent delivery and control. Lerman, Kelley, Vorndran, Kuhn, and LaRue (2002) provided positive reinforcement (access to

Figure 25.2 Examples of alternative behaviors for common classroom behavior problems.

Problem Behavior	Alternative Behavior
Talking back	Positive response such as "Yes, sir" or "OK" or "I understand"; or acceptable question such as "May I ask you a question about that?" or "May I tell you my side?"
Cursing	Acceptable exclamations such as "darn," "shucks."
Being off-task	Any on-task behavior: looking at book, writing, looking at teacher, etc.
Being out of seat	Sitting in seat (bottom on chair, with body in upright position).
Noncompliance	Following directions within _____ seconds (time limit will depend upon age of student); following directions by second time direction is given.
Talking out	Raising hand and waiting quietly to be called on.
Turning in messy papers	No marks other than answers.
Hitting, pinching, kicking, pushing/shoving	Using verbal expression of anger; pounding fist into hand; sitting or standing next to other students without touching them.
Tardiness	Being in seat when bell rings (or by desired time).
Self-injurious or self-stimulatory behaviors	Sitting with hands on desk or in lap; hands not touching any part of body; head up and not touching anything (desk, shoulder, etc.).
Inappropriate use of materials	Holding/using materials appropriately (e.g., writing *only* on appropriate paper, etc.).

Adapted from "Accentuate the Positive . . . Eliminate the Negative," by J. Webber and B. Scheuermann, 1991, *Teaching Exceptional Children, 24*(1), p. 15. Copyright 1991 by Council for Exceptional Children. Used by permission.

toys) and negative reinforcement (escape from demands) in magnitudes ranging from 20 seconds to 300 seconds. They found that reinforcement magnitude only affected responding minimally during treatment and had little effect on maintenance after treatment was discontinued. However, a series of experiments conducted by Athens and Vollmer (2010) "showed the effectiveness of DRA that provided some combination of more immediate, longer duration, or higher quality of reinforcement for appropriate behavior relative to reinforcement for problem behavior" (p. 586).

Reinforce Alternative Behavior Immediately and Consistently

In addition to their potential effectiveness as reinforcers, the stimulus changes selected by the practitioner must be ones that can be delivered immediately and consistently when the alternative behavior occurs. A continuous schedule of reinforcement (CRF) should be used initially for the alternative behavior and then transition to an intermittent schedule. The reinforcer should be presented consistently and immediately following each occurrence of the alternative behavior. After firmly establishing the alternative behavior, the practitioner should gradually thin the reinforcement schedule.

Withhold Reinforcement for the Problem Behavior

The effectiveness of DRA as an intervention for problem behavior depends on the alternative behavior yielding a higher rate of reinforcement than the problem behavior. Maximizing the difference between rates of reinforcement obtained by the two response classes entails withholding all reinforcement for the problem behavior (i.e., extinction schedule).

Ideally, the alternative behavior would always receive reinforcement (at least initially) and the problem behavior would always be on extinction. As Vollmer, Roane, Ringdahl, and Marcus (1999) noted, "Perfect implementation of differential reinforcement entails providing reinforcers as immediately as possible after an appropriate behavior occurs (e.g., within 5 s). Treatment effects may degrade as the delay to reinforcement increases, especially if inappropriate behavior is occasionally reinforced" (p. 21). However, practitioners must often implement DRA schedules in less than optimal conditions, in which some occurrences of the alternative behavior do not produce reinforcement, and the problem behavior sometimes inadvertently produces the reinforcer.

Results from a study by Vollmer and colleagues (1999) suggest that even when such treatment "mistakes" occur, differential reinforcement may still be effective. These researchers compared a "full implementation" of DRA, in which 100% of instances of alternative behavior were reinforced (CRF) and 0% of instances of aberrant behavior were reinforced (extinction), with various levels of "partial implementation." For example, only one in every four instances of appropriate behavior produced reinforcement with a 25%/75% schedule, whereas a reinforcer followed three of every four instances of inappropriate behavior. As expected, full implementation of differential reinforcement produced the greatest effects, with inappropriate behavior being "virtually replaced by appropriate behavior, and lower levels of implementation eventually reducing treatment efficacy if the schedule of reinforcement favored inappropriate behavior" (p. 20). Figure 25.3 shows the results for Rachel, a 17-year-old student with profound developmental disabilities who engaged in self-injurious behavior (SIB; e.g., head hitting and hand biting) and aggression toward others (e.g., scratching, hitting, hair pulling).

An important and perhaps surprising finding of the Vollmer and colleagues (1999) study was that partial implementation was effective under certain conditions. During partial implementation, the participants' behavior showed a "disproportional tendency toward appropriate behavior" (p. 20) if they had prior exposure to full implementation. The researchers concluded that this finding suggests the possibility of intentionally thinning implementation levels prior to extending differential reinforcement interventions to settings in which maintaining treatment fidelity will be difficult. Recognizing that treatment effects might erode over time, they recommended that full implementation booster sessions be conducted periodically to re-establish the predominance of appropriate behavior.

Watch for Treatment Relapse

A problem behavior previously reduced by DRA may occur more frequently when the reinforcement schedule for the alternative behavior is thinned to levels that can be maintained in the client's everyday environment, when treatment shifts from a clinical setting to the natural settings, or when new therapists and/or caregivers begin working with the client. Problem behavior treated with DRA may ultimately prove more resistant to extinction when the DRA contingency is weakened or compromised (Nevin, Tota, Torquato, & Shull, 1990). Mace and colleagues (2010) conducted basic and translational research experiments exploring the persistence-strengthening effects of DRA and a possible solution.

Resurgence refers to the reoccurrence of a previously reinforced behavior when reinforcement for an alternative behavior is terminated or decreased (Lattal & St. Peter Pipkin, 2009; Lieving & Lattal, 2003). Fuhrman, Fisher, and Greer (2016) described resurgence in the context of FCT "as the recurrence of a previously reinforced response (e.g., destructive behavior) when alternative reinforcement is challenged (e.g., extinction or schedule thinning)" (p. 884). Also, spontaneous recovery (i.e., the reappearance of the problem behavior after it has diminished to its pre-reinforcement level or stopped entirely) and response variation (i.e., the emergence of novel behaviors during the extinction process) relate to resurgence (see Chapter 24). Research has identified several factors that may influence resurgence during applications of DRA, such as magnitude of reinforcement, thinning the schedules of reinforcement, response effort (e.g., Wilson, Glassford, & Koerkenmeier, 2016), and lapses in treatment integrity (e.g., Fuhrman et al., 2016).

The resurgence evoked by extinction might not be the problem behavior; alternative behaviors can resurge as well (Hoffman & Falcomata, 2014). Bloom and Lambert (2015) recommend that clinicians reduce resurgence of the problem behavior by reinforcing multiple alternative behaviors. An analog experiment by Lambert, Bloom, Samaha, Dayton, and Rodewald (2015) provides some empirical support for this

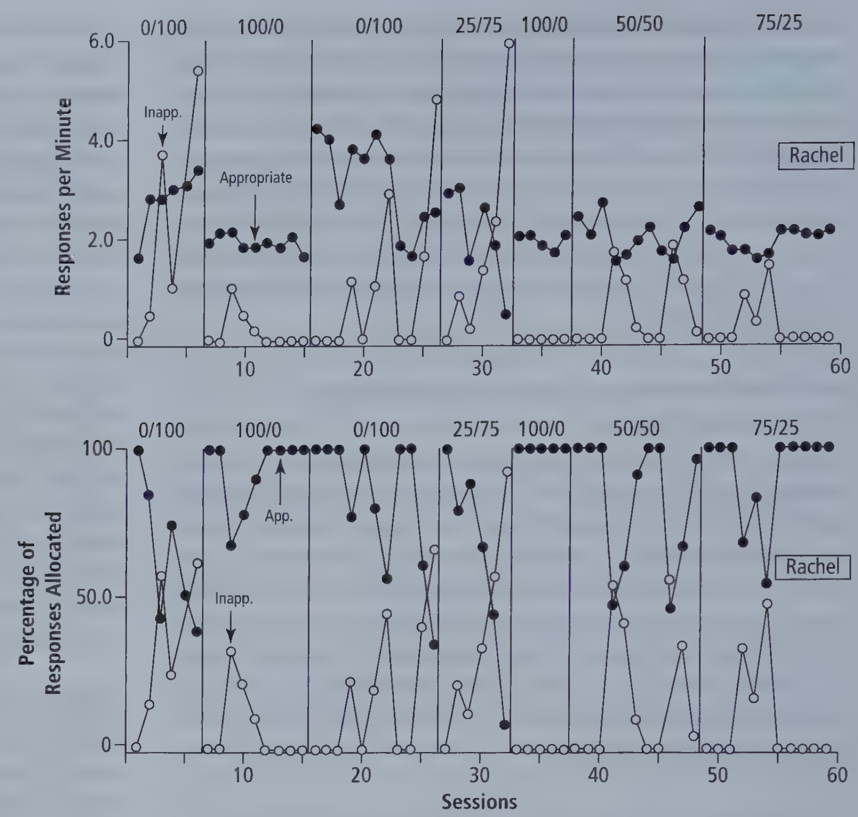

Figure 25.3 Number of appropriate and inappropriate responses per minute (upper panel) and allocation of appropriate and inappropriate behavior (lower panel) by a 17-year-old student with profound developmental disabilities during full (100/0) and partial levels of implementation of DRA.

"Evaluating Treatment Challenges with Differential Reinforcement of Alternative Behavior" by T. R. Vollmer, H. S. Roane, J. E. Ringdahl, and B. A. Marcus, 1999, *Journal of Applied Behavior Analysis*, *32*, p. 17. Reproduced with permission of John Wiley & Sons Inc.

suggestion. Response rates by three women with developmental disabilities on five topographically different devices (i.e., toggle light switch, rocker light switch, slide light switch, cord switch, and personal alarm button) were measured. The researchers arbitrarily identified one switch as the target response (i.e., problem behavior) and all other switches were designated as alternative behaviors.

After an initial *reinforcement phase* of a high-preference edible item on a fixed ratio (FR) 1 schedule developed independent consistent responding on the target response, an *elimination phase* was implemented in which the target response was placed on extinction and an alternative response (or series of three alternative responses) was reinforced on an FR 1 schedule. In a final *resurgence phase*, all responses were placed on extinction. The procedure used in the elimination phase to reinforce one alternative behavior was analogous to traditional DRA intervention. The researchers dubbed the procedure for reinforcing a series of alternative behaviors *serial DRA*. The results are encouraging: "In all cases, the percentage of total responding allocated toward target response resurgence was less in the serial DRA component than in the traditional DRA component . . . Our data provide preliminary evidence suggesting that serial DRA may produce more durable and desirable outcomes than traditional DRA" (p. 765).

Combine DRA with Other Procedures

Considering that DRA interventions do not specifically provide consequences for the problem behavior, a practitioner will seldom apply DRA as a single intervention if the problem behavior is destructive, is dangerous to the learner or to others, or interferes with health and safety. In these situations, the practitioner might combine DRA with other reductive procedures (e.g., response blocking, time-out, stimulus fading, differential reinforcement of other behavior) to produce a more potent intervention (e.g., Goh, Iwata, & Kahng, 1999; Jessel & Borrero, 2014; Patel, Piazza, Kelly, Oschsher, & Santana, 2001).

For example, Ringdahl and colleagues (2002) compared the effects of DRA, with and without instructional fading, on the frequency of problem behaviors of an 8-year-old girl, Kristina, who had been diagnosed with autism and functioned in the moderate range of developmental disabilities. Kristina's problem behaviors during academic tasks—destruction: throwing, tearing, or breaking work materials; aggression: hitting, kicking, biting; and self-injurious behavior: biting herself—had become so severe that she had been admitted to a hospital day treatment program. Because a previous functional analysis revealed that Kristina's problem behavior was maintained by escape from instructions to complete tasks, the DRA procedure in both conditions consisted of giving Kristina a 1-min break from the task and access to leisure materials contingent on independent completion of the task (e.g., counting items, matching cards with the same colors or shapes) without exhibiting problem behavior. Kristina received instructions to complete a work task at approximately one instruction every other minute during the DRA without instructional fading condition. During the DRA with instructional fading, Kristina received no instructions during the first three sessions, then one instruction every 15 minutes. The number of instructions given gradually increased until it equaled the number in the DRA without the fading condition. Problem behavior was high at the outset of the DRA without the instructional fading condition but decreased across sessions to a mean of 0.2 responses per minute over the final three sessions

(see Figure 25.4). During DRA with instructional fading, problem behavior was low from the outset and occurred during only two sessions (Sessions 9 and 14). Over the final three sessions of DRA with instructional fading, Kristina exhibited no problem behavior, and the instruction rate was equal to the DRA without instructional fading (0.5 instruction per minute).

DIFFERENTIAL REINFORCEMENT OF OTHER BEHAVIOR (DRO)

Reynolds (1961) described the differential reinforcement of other behavior as "reinforcement for not responding" (p. 59). A practitioner applying **differential reinforcement of other behavior (DRO)** delivers reinforcement contingent on the problem behavior not occurring throughout intervals of time (*interval DRO*) or at specific moments of time (*momentary DRO*).

Researchers have demonstrated the effectiveness of DRO in reducing a wide range of problem behaviors in a variety of subject populations, including disruptive classroom behavior by typically developing students (Austin, Groves, Reynish, & Francis, 2015), tics in youth with Tourette syndrome (Capriotti et al., 2017), stereotypic vocalizations and pica in children with autism (Rozenblat, Brown, Brown, Reeve, & Reeve, 2009; Slocum et al., 2017), and self-injurious behavior by adults with severe intellectual disabilities (Lindberg, Iwata, Kahng, & DeLeon, 1999). Behavior analysts have used DRO to reduce biting, chewing, and pawing by horses (Fox, Bailey, Hall, & St. Peter, 2012; Fox & Belding, 2015).

Four behavioral processes have been suggested as potential explanations for the effects of DRO (Jessel & Ingvarsson, 2016; Poling & Ryan, 1982).

> First, the presentation of the reinforcer could function as an abolishing operation (i.e., satiation) and temporarily reduce or eliminate target responding. Second, the disruption of the response–reinforcer contingency could result in extinction. Third, delaying access to reinforcers could suppress target responding through punishment. Fourth, other behavior could be strengthened by adventitious reinforcement, resulting in displacement of the target behavior.
>
> It is likely that each of these four processes could be operating on different occasions, or multiple processes could operate at the same time, depending on the DRO arrangement and the reinforcer used. (Jessel & Ingvarsson, 2016, p. 991–992)

Applied behavior analysts implement DRO with two primary methods. With *interval DRO*, if the problem behavior did not occur during a predetermined time interval, a reinforcer is delivered; any instance of the problem behavior during that interval resets the interval and postpones reinforcement.[3] With *momentary DRO*, absence of the problem behavior at predetermined moments in time produces reinforcement; instances of the target behavior at other points in time do not alter when the next opportunity for reinforcement becomes available. The combinations of an interval or momentary omission requirement implemented on either a fixed or a variable schedule yield four basic DRO arrangements shown in Figure 25.5 (Lindberg et al., 1999).

Interval DRO

The following sections introduce procedures for applying fixed-interval DRO, variable-interval DRO, fixed-momentary DRO, and variable-momentary DRO schedules.

Fixed-interval DRO (FI-DRO)

Most applications of interval DRO apply the omission requirement at the end of successive time intervals of equal duration. To apply a **fixed-interval DRO (FI-DRO)** schedule, a behavior analyst (a) establishes a standard interval of time; (b) delivers reinforcement at the end of that interval if the problem did not occur during the interval; and (c) upon any occurrence of the problem behavior, immediately resets the timer to begin a new interval.

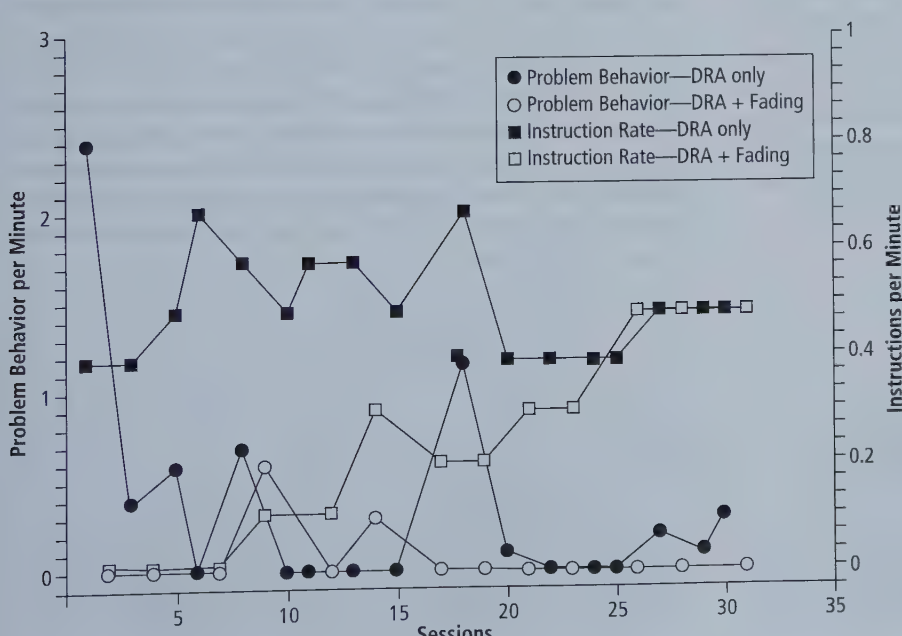

Figure 25.4 Problem behavior by an 8-year-old student with autism and developmental disabilities (left *y*-axis) and instructions given per minute (right *y*-axis) under DRA only and DRA implemented with instructional fading.

Based on "Differential Reinforcement With and Without Instructional Fading" by J. E. Ringdahl, K. Kitsukawa, M. S. Andelman, N. Call, L. C. Winborn, A. Barretto, and G. K. Reed, 2002, *Journal of Applied Behavior Analysis*, *35*, p. 293. Copyright 2002 by the Society for the Experimental Analysis of Behavior, Inc.

For example, Allen, Gottselig, and Boylan (1982) applied an FI-DRO procedure to decrease the disruptive classroom behaviors of third-grade students. They set a kitchen timer to 5-min intervals that continued to run as long as no disruptive behaviors occurred. The timer was reset and a new 5-min interval began if any student engaged in disruptive behavior at any time during the 5-min interval. The class received 1 minute of free time when the timer signaled the end of a 5-min interval without disruptive behavior, which they accumulated and used at the end of the class period.[4]

Behavior analysts can gradually thin the DRO interval and treatment session length as the problem behavior improves (Della Rosa, Fellman, DeBiase, DeQuinzio, & Taylor, 2015). Cowdery and colleagues (1990) used FI-DRO to help Jerry, a 9-year-old who never attended school and spent most of his time hospitalized. He scratched and rubbed his skin so often and hard that he had open lesions all over his body. During treatment, the experimenter left the room and watched Jerry through an observation window. The researchers initially made praise and token reinforcement contingent on 2-min "scratch-free" intervals, which were determined by baseline assessment. If Jerry scratched during the interval, the experimenter entered the room and told him she regretted he had not earned a penny and asked him to try again. Jerry's SIB immediately decreased to zero with the introduction of DRO. Jerry's SIB remained low as the DRO interval and session length were gradually thinned—from three 2-min intervals to three 4-min intervals. Following a brief return to baseline conditions in which Jerry's scratching quickly increased, Cowdery and colleagues reinstated DRO with five intervals per session and increased session length in 1-min increments. Jerry could now earn a total of 10 tokens per session, a token for each interval in which he did not scratch plus a 5-token bonus if he refrained from scratching for all five intervals. Jerry's SIB gradually reduced to zero as session length and DRO intervals were extended. Session 61 consisted of a single 15-min DRO interval, which was followed by one 25- and three 30-min intervals (see Figure 25.6).

Cook, Rapp, and Schulze (2015) used differential negative reinforcement of other behavior (DNRO) with an 8-year-old boy with autism who exhibited problem behavior when a medical alert bracelet was placed on his wrist (e.g., yelling, demands to remove the bracelet, flopping on the floor, hitting others, biting his hand, pulling on and biting the bracelet). For a description of the DNRO procedure and graph of the results, see Chapter 9.

Variable-interval DRO (VI-DRO)

To apply a **variable-interval DRO (VI-DRO)** schedule, a behavior analyst (a) establishes a random sequence of varied intervals of time and (b) delivers reinforcement at the end of each interval if the problem behavior did not occur at any time during the interval. For example, a VI-DRO 10-sec schedule delivers reinforcement contingent on the omission of the target behavior throughout intervals of varying duration that average 10 seconds (e.g., a random sequence of 2-sec, 8-sec, 5-sec, 20-sec, and 15-sec intervals).

Chiang, Iwata, and Dorsey (1979) used VI-DRO to decrease the inappropriate behaviors of a 10-year-old student with developmental disabilities during bus rides to and from school. The boy's disruptive behaviors included aggression (e.g., slapping, poking, hitting, kicking), being out of seat, stereotypic behaviors, and inappropriate vocalizations (e.g., screaming, yelling). Instead of basing the DRO intervals on elapsed time, the researchers used an interesting procedure they described as a "distance-based" DRO schedule. The driver divided the bus route into sections designated by landmarks such as stop signs and traffic lights and mounted a four-digit hand counter on the dashboard of the bus. The counter was within reach of the driver and within view of the student. At each predetermined landmark, the bus driver praised the student's behavior and added one point to the hand counter if no disruptive behaviors had been emitted during the DRO interval. Upon arrival at home or school, the driver recorded the number of points earned on a card and gave the card to the boy's foster father or teacher. The student exchanged the points earned for rewards (e.g., access to toys, home and school privileges, small snacks).

Chiang and colleagues used a two-tier multiple baseline across settings design to evaluate the VI-DRO intervention. During baseline, disruptive behavior ranged from 20% to 100% with an average of 66.2% for the afternoon rides and 0% to 92% with an average of 48.5% in the mornings. When implementing the VI-DRO procedure during the afternoon rides only, disruptive behavior decreased immediately to an average of 5.1% (range of 0% to 40%) during the afternoon rides but remained unchanged during the morning rides. Presenting the intervention also during the morning rides eliminated all disruptive behavior.

Progar and colleagues (2001) implemented VI-DRO as one component of a conjunctive schedule of reinforcement to reduce the aggressive behaviors of Milty, a 14-year-old boy with autism. A conjunctive schedule delivers reinforcement when the requirements of two or more schedule components have been met (see Chapter 13)—in this case, an FR3 schedule for task

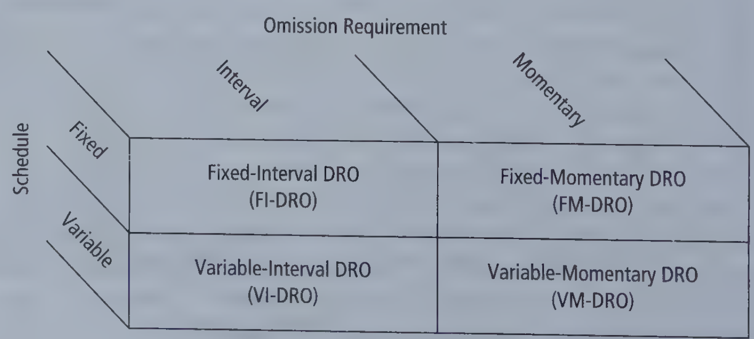

Figure 25.5 Four basic variations of DRO that can be created by combining the omission requirement (interval or momentary) and the schedule of reinforcement (fixed or variable).

"DRO Contingencies: An Analysis of Variable-Momentary Schedules" by J. S. Lindberg, B. A. Iwata, S. W. Kahng, & I. G. DeLeon, 1999. *Journal of Applied Behavior Analysis, 32*, p. 125. Reproduced with permission of John Wiley & Sons Inc.

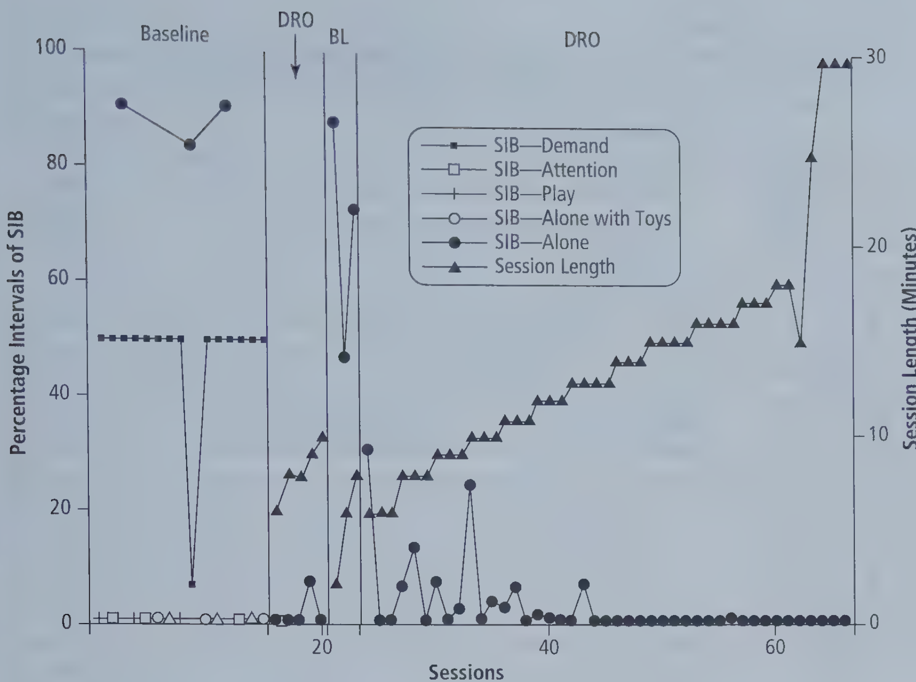

Figure 25.6 Percent intervals of SIB by Jerry during baseline and DRO and duration of DRO sessions (right *y*-axis). Other data points during the first baseline phase show the results of functional analysis, confirming that Jerry's SIB occurred most often when he was alone.

"Effects and Side Effects of DRO as Treatment for Self-injurious Behavior" by G. Cowdery, B. A. Iwata, and G. M. Pace, 1990, *Journal of Applied Behavior Analysis*, *23*, p. 500. Reproduced with permission of John Wiley & Sons Inc.

completion and a VI 148-sec schedule for the absence of aggression. Milty received an edible reinforcer each time he completed three components of a task (e.g., making his bed, vacuuming, straightening objects in his room) in the absence of aggression for the duration of the variable interval. An occurrence of aggression prior to completing the FR 3 requirement reset both components of the conjunctive schedule. This intervention produced a substantial reduction of aggressive behavior.

Momentary DRO

On a momentary DRO schedule, reinforcement is contingent on the absence of the problem behavior at the exact time each interval ends, rather than throughout the entire interval, as with interval DRO. Occurrences of the problem behavior between those moments have no effect.

Fixed-momentary DRO (FM-DRO)

To implement a **fixed-momentary DRO (FM-DRO)** schedule, the practitioner (a) establishes a standard interval of time; (b) observes the participant at the moment each interval ends; and (b) delivers reinforcement at the end of each interval if the problem behavior is not occurring at that moment.

In their review of research on momentary DRO schedules, Hammond, Iwata, Fritz, and Dempsey (2011) concluded that FM-DRO schedules "generally have been ineffective as treatment for problem behavior. Because most early research on FM DRO included presentation of a signal at the end of the DRO interval, it is unclear whether the limited effects of FM-DRO were due to (a) the momentary response requirement of the schedule per se or (b) discrimination of the contingency made more salient by the signal" (p. 69).[5] The researchers addressed this question by comparing the effects of signaled versus unsignaled FM-DRO. Four students with special needs served as participants—(1) Seth, a deaf and learning-impaired, aggressive 6-year-old; (2) Alex, with autism and seizure disorder, an aggressive 14-year-old; (3) Curtis, with autism, an aggressive 13-year-old; and (4) Abby, a 19-year-old with profound intellectual disabilities, autism, and seizure disorder. Functional analyses revealed that positive reinforcement in the form of access to preferred items maintained the participants' problem behaviors.

The four participants had access to preferred items during baseline. The signaled and unsignaled conditions were identical except for the signal.

> *Signaled FM DRO.* The experimenter covertly held the reinforcer to ensure that it could be delivered quickly but that no additional movements (e.g., reaching for the reinforcer) might inadvertently signal the end of an interval. Three seconds prior to the end of an interval, the experimenter (positioned directly in front of or next to the subject) signaled impending reinforcement delivery by holding the reinforcer above her head. If no problem behavior was occurring at the precise second the interval clocked out, the reinforcer (30-s access to the toy box or video, or one edible item) was delivered. If problem behavior was occurring at that second, the signal was removed, and the reinforcer was withheld until the next scheduled interval.
>
> *Unsignaled FM DRO.* This condition was similar to the signaled condition, except that the experimenter did not signal impending reinforcer delivery. Rather, the experimenter quickly delivered the reinforcer contingent on the absence of problem behavior when the interval ended. (p. 75)

Seth and Alex had rapid reductions in aggression during the signaled FM-DRO conditions (see Figure 25.7). However, the signaled FM-DRO conditions produced different results for Curtis and Abby (see Figure 25.8). Curtis's aggression increased

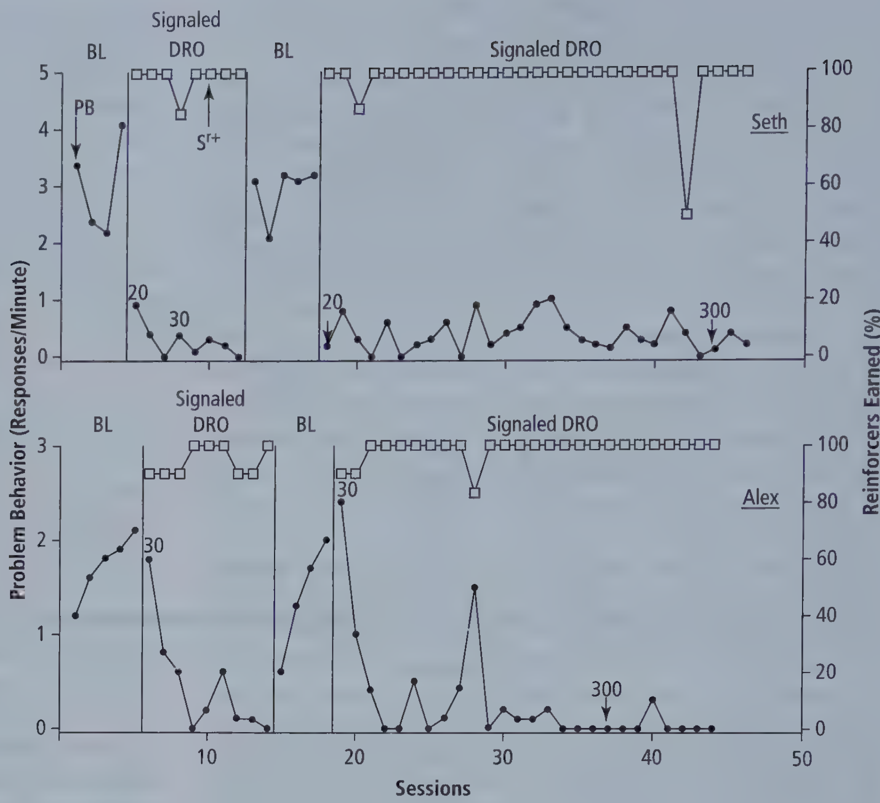

Figure 25.7 Responses per minute of problem behavior (PB) during baseline (BL) and signaled DRO conditions, and percentage of available reinforcers (S^{r+}) earned during DRO conditions for Seth and Alex. Numbers above the data path for problem behavior indicate DRO interval lengths (in seconds) that were in effect during the first and final sessions of each phase.

"Evaluation of Fixed Momentary DRO Schedules Under Signaled and Unsignaled Arrangements" by J. L. Hammond, B. A. Iwata, J. N. Fritz, and C. M. Dempsey, 2011, *Journal of Applied Behavior Analysis*, *44*, 76. Reproduced with permission of John Wiley & Sons Inc.

during the first introduction of the signaled FM-DRO condition, then greatly decreased by the end of the first introduction. His aggression did not decrease during the second signaled FM-DRO condition, but decreased to zero during the reintroduction of the unsignaled FM-DRO condition. Similar to Curtis's behavior, Abby's head hitting decreased under the second and final unsignaled DRO phase, all the while earning a large proportion of available reinforcers. "[T]hese data indicate that momentary DRO should be used with caution, because very subtle therapist responses (e.g., reaching for the programmed reinforcer) may function as signals that could render FM DRO ineffective" (Hammond et al., 2011, p. 80).

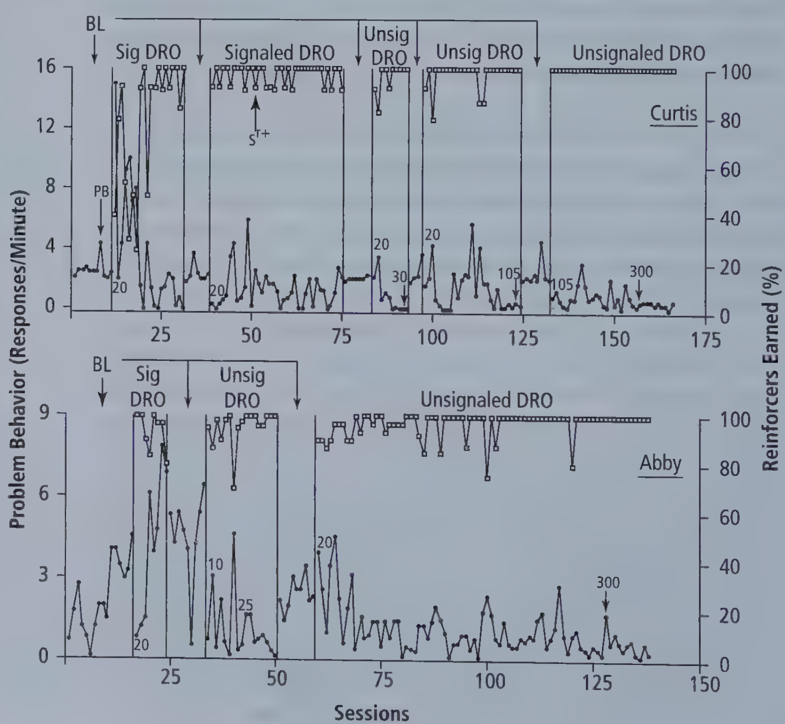

Figure 25.8 Responses per minute of problem behavior (PB) during baseline (BL) and signaled DRO conditions, and percentage of available reinforcers (S^{r+}) earned during DRO conditions for Curtis and Abby. Numbers above the data path for problem behavior indicate DRO interval lengths (in seconds) that were in effect during the first and final sessions of each phase.

Variable-momentary DRO (VM-DRO)

In a **variable-momentary DRO (VM-DRO)** schedule, the practitioner (a) establishes a random sequence of varied intervals of time and (b) delivers reinforcement at the end of each interval if the problem behavior is not occurring at that precise moment. Lindberg and colleagues (1999) used a VM-DRO intervention to help Bridget, a 50-year-old woman with severe developmental disabilities, who often banged her head and body. A functional analysis indicated that social-positive reinforcement maintained Bridget's self-injurious behaviors (SIB). During the VM-DRO intervention, SIB was placed on extinction and Bridget received 3 to 5 seconds of attention from the therapist if she did not bang her head or hit herself when each interval ended. A VM-DRO 15-sec schedule was implemented for five sessions following baseline, and Bridget's SIB decreased abruptly to almost zero (see Figure 25.9). Following a second baseline phase in which Bridget's SIB increased, the researchers reintroduced VM-DRO with a mean interval of 11 seconds. SIB did not decrease as quickly during the second treatment condition. After several sessions in which SIB occurred at low rates, the interval length was increased to 22 seconds and eventually to the maximum target interval of 300 seconds.

Interval DRO has been used more widely than momentary DRO. Some researchers have found that interval DRO is more effective than momentary DRO for suppressing problem behavior, and that momentary DRO might be most useful in maintaining reduced levels of problem behavior produced by interval DRO (Barton, Brulle, & Repp, 1986; Repp, Barton, & Brulle, 1983). Lindberg and colleagues (1999) noted two potential advantages of VM-DRO schedules over FI-DRO schedules. First, the VM-DRO schedule appears more practical because the practitioner need not monitor the participant's behavior at all times. Second, data obtained by these researchers showed that participants obtained higher overall rates of reinforcement with VM-DRO than with FI-DRO.

Guidelines for Using DRO

In addition to the importance of selecting potent reinforcers, we recommend the following guidelines for the effective use of DRO.

Set Initial DRO Intervals That Ensure Frequent Reinforcement

Practitioners should establish an initial DRO time interval that ensures that the learner's current level of behavior will contact reinforcement when the DRO contingency is applied. For example, Cowdery and colleagues (1990) initially made praise and token reinforcement contingent on 2-min "scratch-free" intervals because that was "the longest we had previously seen Jerry refrain from scratching while left alone" (p. 501). Beginning with an interval that is equal to or slightly less than the mean baseline interresponse time (IRT) usually will make an effective initial DRO interval. To calculate a mean IRT, the practitioner divides the total duration of all baseline measurements by the total number of responses recorded during baseline. For example, if a total of 90 responses were recorded during 30 minutes of baseline measurement, the mean IRT would be 20 seconds (i.e., 1800 seconds ÷ 90 responses). Using these baseline data as a guide, the practitioner could set the initial DRO interval at 30 seconds or less.

Do Not Inadvertently Reinforce Other Undesirable Behaviors

Reinforcement on a "pure" DRO schedule is contingent on a very general response class that is defined only by the absence of the targeted problem behavior. Consequently, a "pure" DRO is typically used as a treatment of choice for serious behavior problems that occur at very high rates by people whose current repertoires provide few, if any, other behaviors that might function as alternative behaviors and for whom just about anything else they might do is less of a problem than the target behavior.

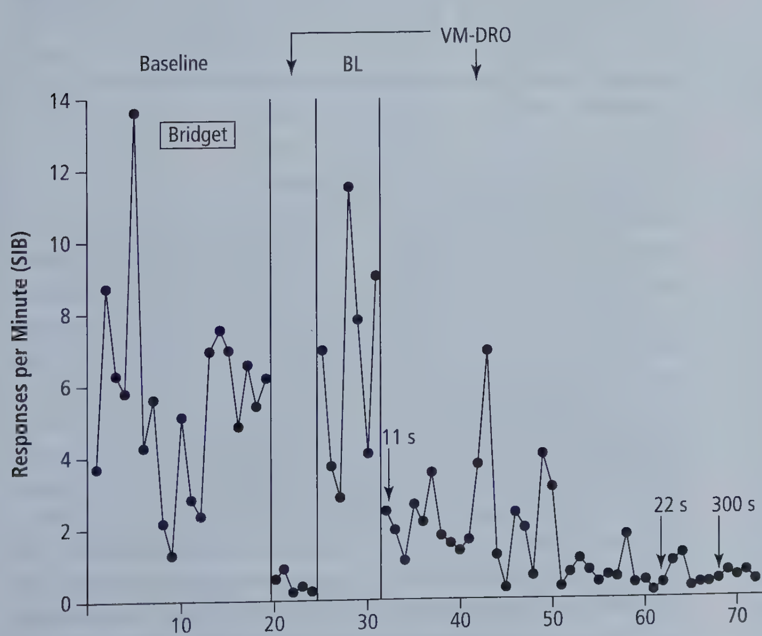

Figure 25.9 Responses per minute of self-injurious behavior (SIB) during baseline and treatment conditions.

"DRO Contingencies: An Analysis of Variable-momentary Schedules" by J. S. Lindberg, B. A. Iwata, S. W. Kahng, and I. G. DeLeon, 1999. *Journal of Applied Behavior Analysis, 32*, p. 131. Reproduced with permission of John Wiley & Sons Inc.

Because DRO does not require any certain behaviors to be emitted for reinforcement, whatever the person is doing when reinforcement is delivered is likely to occur more often in the future (Jessel, Borrero, & Becraft, 2015). Therefore, practitioners using DRO must be careful not to strengthen inadvertently other undesirable behaviors. When using DRO, the practitioner should deliver reinforcement at the intervals or moments in time specified by the schedule contingent on the absence of the problem behavior *and* the absence of any other significant inappropriate behaviors.

Gradually Increase the DRO Interval

After the initial DRO interval effectively controls the problem behavior, the practitioner can increase the DRO interval, by increasing the interval through a series of initially small and gradually increasing increments.

Poling and Ryan (1982) suggested three procedures for increasing the duration of the DRO interval.

1. Increase the DRO interval by a *constant duration* of time. For example, a practitioner could, at each opportunity for an interval increase, lengthen the DRO interval by 15 seconds.
2. Increase intervals *proportionately*. For example, a practitioner, at each opportunity to change the interval, could increase the DRO interval by 10%.
3. Change the DRO interval each session based on the *learner's performance*. For example, a practitioner could set the DRO interval for each session equal to the mean IRT from the preceding session.

If problem behavior worsens when a longer DRO interval is introduced, the practitioner can decrease the duration of the interval to a level that again controls the problem behavior. The DRO interval can then be extended with smaller, more gradual durations after previously obtained reductions in problem behavior have been re-established.

Extend the Application of DRO to Other Settings and Times of Day

When the frequency of the problem behavior is reduced substantially in the treatment setting, the DRO intervention can be introduced during other activities and times in the person's natural environment. Having teachers, parents, or other caregivers begin to deliver reinforcement on the DRO schedule will help extend the effects. For example, Cowdery and colleagues (1990) began to implement the DRO intervention at other times and places during the day after Jerry's SIB was under good control during treatment sessions (see Figure 25.6). At first, various staff members would praise Jerry and give him tokens for refraining from scratching during single 30-min DRO intervals during leisure activities, instructional sessions, or free time. Then they began adding extra 30-min DRO intervals until the DRO contingency was extended to all of Jerry's waking hours. Jerry's SIB decreased sufficiently to allow him to be discharged to his home for the first time in 2 years. Jerry's parents were taught how to implement the DRO procedure at home.

Combine DRO with Other Procedures

DRO can be used as a single intervention. However, as with DRA, including DRO in a treatment package with other behavior-reduction procedures often yields more efficient and effective behavior change. De Zubicaray and Clair (1998) used a combination of DRO, DRI, and a restitution (punishment) procedure to reduce the physical and verbal abuse and physical aggression of a 46-year-old woman with intellectual disabilities who lived in a residential facility for people with chronic psychiatric disorders. Further, the results of three experiments by Rolider and Van Houten (1984) showed that an intervention consisting of DRO plus reprimands was more effective than DRO alone in decreasing a variety of problem behaviors by children (e.g., physical abuse by a 4-year-old girl toward her baby sister, thumb sucking by a 12-year-old boy, and bedtime tantrums).

DRO can also be added as a supplement to an intervention that has produced insufficient results. McCord, Iwata, Galensky, Ellingson, and Thomson (2001) added DRO to a stimulus fading intervention that was "having limited success" in decreasing the problem behaviors of Sarah, a 41-year-old woman with severe intellectual disabilities and visual impairment. Her problem behaviors included severe self-injurious behavior, property destruction, and aggression evoked by noise. Gradually increasing the noise volume by 2 dB when DRO was in effect, "a therapist delivered a preferred edible item (half a cheese puff) to Sarah following each 6-s interval in which problem behavior was not observed. If problem behavior occurred, the food was withheld and the DRO interval was reset" (p. 455). Each time Sarah completed three consecutive 1-min sessions with no occurrences of the problem behavior, the researchers increased the DRO interval by 2 seconds. This schedule thinning continued until Sarah could complete the session with no occurrences of the problem behavior. The therapist then delivered the edible item only at the end of the session. The addition of DRO to the intervention produced an immediate decrease in Sarah's problem behavior, which remained at or near zero in the treatment setting for more than 40 sessions (see Chapter 6, the bottom graph of Figure 6.6). Probes conducted in noisy conditions after treatment ended showed that the treatment effects had maintained and generalized to Sarah's home.

Recognize the Limitations of DRO

Although DRO can be highly effective for reducing problem behaviors, it is not without shortcomings. With interval DRO, reinforcement is delivered contingent only on the absence of problem behavior during the interval, even though another inappropriate behavior might have occurred during that time. For instance, let us assume that a 20-sec interval DRO is to be implemented to reduce the facial tics of an adolescent with Tourette syndrome. Reinforcement will be delivered at the end of each 20-sec interval containing no facial tics. However, if the adolescent engages in cursing behavior at any time during the interval or at the end of the interval, reinforcement will still be delivered. It is possible that reinforcement delivered contingent on the absence of facial tics will occur in close temporal proximity to cursing, thereby inadvertently strengthening

another inappropriate behavior. In such cases, the length of the DRO interval should be shortened and/or the definition of the problem behavior expanded to include the other undesirable behaviors (e.g., reinforcement contingent on the absence of facial tics *and* cursing).

With momentary DRO, reinforcement is delivered contingent on the problem behavior not occurring at the end of each interval, even though the inappropriate behavior might have occurred during the interval. Continuing the previous example, on an FM-DRO 20-sec schedule, reinforcement is delivered at each successive 20th second if facial tics are not occurring at those precise moments, even if tics occurred for 50%, 75%, or even 95% of the interval. In such circumstances, the practitioner should use interval DRO and reduce the length of the DRO interval.

Another consideration is the number of resources that may be available for labor-intensive procedures. Rozenblat and colleagues (2009) found that if DRO intervals are extremely short—in their case, as low as 1 sec—it might be clinically impossible for a single analyst or practitioner to implement the procedure. Working alone and trying to conduct a session with other students, time a series of intervals, collect data and record performance, and deliver reinforcers is likely to exceed a single person's capability. Thus, practitioners would be advised to assess staff resources before launching a DRO program.

DIFFERENTIAL REINFORCEMENT OF LOW RATES OF RESPONDING (DRL)

A practitioner applying **differential reinforcement of low rates (DRL)** delivers reinforcement (a) following each occurrence of the target behavior that is separated from the previous response by a minimum amount of time or (b) contingent on the number of responses within a period not exceeding a predetermined criterion. In laboratory research, Ferster and Skinner (1957) found that delivering a reinforcer following a response that had been preceded by increasingly longer intervals of time without a response reduced the overall rate of responding. Catania (2013) describes typical DRL behavior found in laboratory research.

> In DRL performance, responding is unlikely to extinguish, because decreasing low rates produce even more reinforcers. Once some responding has been reinforced, response rate typically increases, but once it has done so responses follow each other more closely so fewer meet the scheduled criterion, and response rate decreases once more, and so on. Typically the responding stabilizes at some value, oscillating between increased rates accompanied by decreased reinforcement and decreased rates accompanied by increased reinforcement. A pigeon's pecking can be maintained over long periods by such contingencies. Thus, DRL performance is highly resistant to change, though its rate remains relatively low. It therefore again illustrates the independence of response strength and response rate (Nevin & Grace, 2000). (p. 209)

Because reinforcement with a DRL schedule is delivered following an *occurrence* of the target behavior—as contrasted with DRO, in which reinforcement is contingent on the *absence* of the behavior—behavior analysts use DRL to decrease the rate of a behavior that occurs too frequently, but not to eliminate the behavior entirely. A practitioner may identify a certain behavior as a problem behavior not because of its form, but because the behavior occurs too often. For example, a student asking for help by raising his hand or coming to the teacher's desk during independent seatwork is appropriate at a limited rate, but a problem behavior if it occurs too frequently.

Some learners may emit a behavior less frequently when told to do the behavior less often, or when given rules stating an appropriate rate of response. When instruction alone does not reduce the behavior to an acceptable rate, the practitioner may need to use a consequence-based intervention. DRL offers practitioners an intervention for diminishing problem behaviors that is stronger than instruction alone but still falls short of more restrictive consequences (e.g., punishment). Deitz (1977) named and described three DRL procedures: full-session DRL, interval DRL, and spaced-responding DRL.

Full-session DRL

In a **full-session DRL** schedule, reinforcement is delivered when responding during an entire instructional or treatment session is equal to or below a predetermined criterion. If the number of responses exceeds the specified limit during the session, reinforcement is withheld. For example, a teacher applying full-session DRL with a criterion limit of four disruptions per class period would provide reinforcement at the end of the class period contingent on four or fewer disruptions. Full-session DRL is an easy-to-apply intervention for problem behaviors in education and treatment settings.

Deitz and Repp (1973) demonstrated the efficacy and manageability of full-session DRL for diminishing classroom misbehavior. They decreased the talk-outs of an 11-year-old boy with developmental disabilities. During 10 days of baseline, the student averaged 5.7 talk-outs per 50-minute session. With the introduction of full-session DRL, the student was allowed 5 minutes for play at the end of the day contingent on 3 or fewer talk-outs during a 50-minute session. Talk-outs during the DRL condition decreased to an average of 0.93 talk-out per 50 minutes. A return to baseline slightly increased the talk-outs to an average of 1.5 per session.

Austin and Bevan (2011) implemented a variation of full-session DRL with three female elementary students who engaged in excessive attention-seeking behaviors that affected work completion in a timely manner. The researchers set the number of requests for assistance each student was allowed to "reflect not only a reduction in baseline rates but also the number of requests the teacher thought was reasonable for each child to make in a 20-min work period" (p. 454). The DRL intervention was implemented as follows:

> At the beginning of independent work sessions, each child received a small index card with boxes corresponding to the number of requests allowed during the session plus one (e.g., Elin was allowed three bids for attention, so her card had four boxes). Each time the child requested attention from the teacher, the teacher responded to the child's request (up to the number of responses allocated for the

session) and initialed one of the boxes on the child's card. If the child exceeded the number of allowable requests, the teacher was instructed to initial the remaining box but not to interact with the child. However, none of the children ever exceeded the number of responses eligible for attention during the DRL conditions. If the child had at least one blank box at the end of the work session, she earned a point for her team. No additional points were awarded if more than one box was left empty, because we wanted the children to use the opportunities for assistance or attention that were available to them. (p. 454)

Because the children's requests within the DRL-imposed limit were reinforced as they occurred during the session, an appropriate procedure given the target behavior, we identify Austin and Bevan's (2011) intervention as a variation of full-session DRL. A reversal design demonstrated the intervention's effectiveness in reducing each student's rate of attention-seeking behavior (see Figure 25.10). The procedure earned high marks on social validity assessments conducted at the end of the study. The teacher found the DRL schedule easy to implement and integrate into ongoing classroom routines and reported she planned to continue using it. The children indicated they were happy to use the check-box cards, liked earning points for their group, and wanted their teacher to continue using the cards.

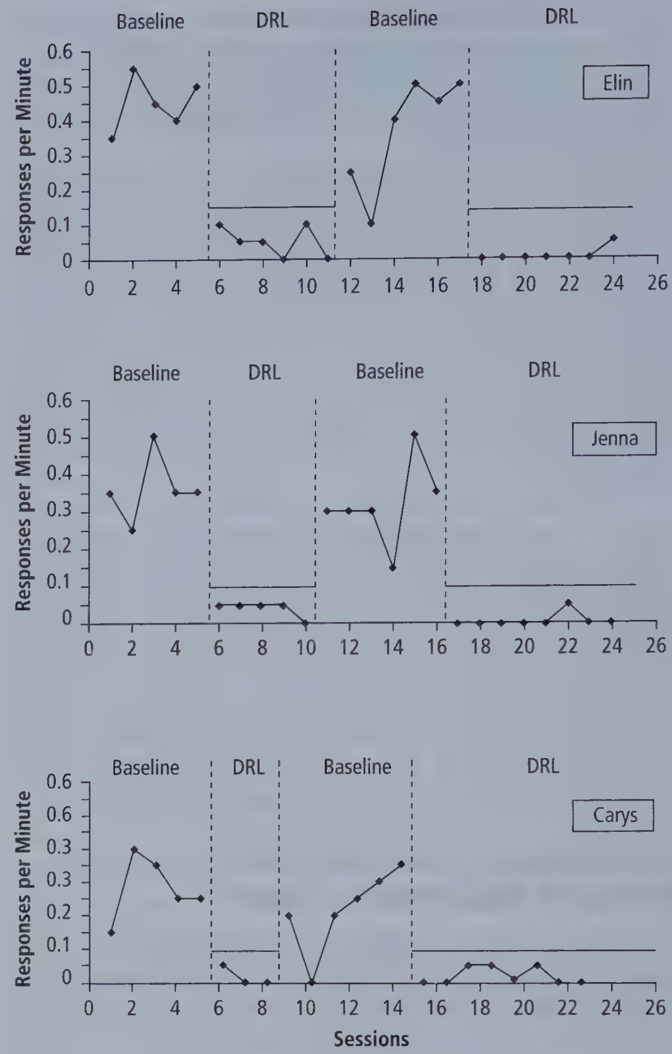

Figure 25.10 Rates of requesting attention across conditions. The solid horizontal line in the DRL phases represents the limit on responding specified by the DRL schedule.

"Using Differential Reinforcement of Low Rates to Reduce Children's Requests for Teacher Attention" by J. L. Austin and D. Bevan, 2011, *Journal of Applied Behavior Analysis*, *44*, p. 456. Used by permission. Reproduced with permission of John Wiley & Sons Inc.

Interval DRL

To apply an **interval DRL** schedule of reinforcement, the practitioner divides the total session into a series of equal intervals of time and provides reinforcement at the end of each interval in which the number of occurrences of the problem behavior was equal to or below a criterion limit. If the learner exceeds the criterion number of responses during an interval, the practitioner removes the opportunity for reinforcement and begins a new interval.

Deitz and colleagues (1978) used an interval DRL schedule of reinforcement to reduce the disruptive behaviors of a student with learning disabilities. The 7-year-old student had several difficult classroom misbehaviors (e.g., running, shoving, pushing, hitting, throwing objects). The student received a sheet of paper ruled into 15 blocks, with each block representing a 2-min interval. A star was placed in a block each time the student completed 2 minutes with 1 or no misbehaviors. Each star permitted the student to spend 1 minute on the playground with the teacher. If the student emitted 2 misbehaviors during the interval, the teacher immediately started a new 2-min interval.

Spaced-responding DRL

Using a **spaced-responding DRL** schedule of reinforcement, the practitioner delivers a reinforcer following an occurrence of a response that is separated from the previous response by at least a specified amount of time.[6] As you will recall from Chapter 4, *interresponse time (IRT)* is the technical term for the duration of time between two responses. IRT and rate of responding are directly correlated: The longer the IRT, the lower the overall rate of responding; shorter IRTs correlate with higher response rates. When reinforcement is contingent on longer IRTs, response rate will decrease.

Favell, McGimsey, and Jones (1980) used a spaced-responding DRL schedule of reinforcement and response prompts to decrease the rapid eating of four persons with profound developmental disabilities. At the start of treatment, reinforcement was contingent on short independent pauses (IRTs) between bites of food. As treatment progressed, gradually increasing longer and longer pauses between bites were required for reinforcement. The researchers also manually prompted a separation between bites of food and faded out those response prompts when a minimum of 5-sec pauses occurred independently between approximately 75% of all bites. Finally, Favell and colleagues gradually thinned food reinforcement and praise. The frequency of eating was decreased from a pretreatment baseline average of 10 to 12 bites per 30 seconds to 3 to 4 bites per 30 seconds during the spaced-responding DRL condition.

Singh, Dawson, and Manning (1981) used a spaced-responding DRL intervention to reduce the stereotypic responding (e.g., repetitive body movements, rocking) of three teenage girls with profound developmental disabilities. During the first phase of spaced-responding DRL intervention, the therapist praised each girl whenever she emitted a stereotypic response at least 12 seconds after the last response. One of the experimenters timed the intervals and used a system of automated lights to signal the therapist when reinforcement was available. After the DRL 12-sec IRT resulted in an abrupt decrease in stereotypic behavior by all three girls (see Figure 25.11), Singh and colleagues systematically increased the IRT criterion to 30, 60, and then 180 sec. The spaced-responding DRL procedure not only produced substantial reductions in stereotypic responding in all three subjects but also had the concomitant effect of increasing appropriate behavior (e.g., smiling, talking, playing).

Most behavior-reduction procedures that manipulate consequences have the potential to reduce behavior to zero occurrences. Spaced-responding DRL is unlikely to do that. For that reason, spaced-responding DRL is an important intervention for diminishing behavior that should still continue but at a slower rate. A spaced-responding DRL contingency tells learners that their behavior is acceptable, but they should do it less often. For example, a teacher could use a spaced-responding DRL schedule to diminish a student's problem behavior of asking too many questions. The questions occurred so frequently that they interfered with the classroom learning and teaching. To intervene, the teacher could respond to the student's question if

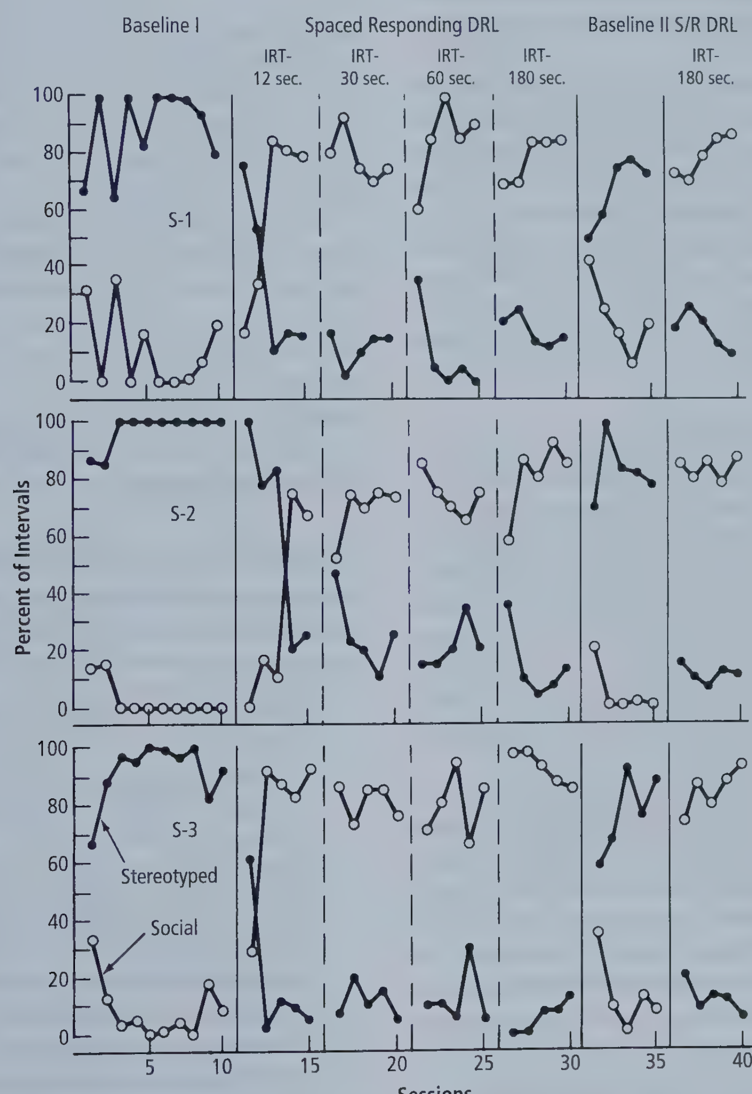

Figure 25.11 Effects of spaced-responding DRL on stereotypic responding of three teenage girls with profound developmental disabilities.

"Effects of Spaced Responding DRL on the Stereotyped Behavior of Profoundly Retarded Persons" by N. N. Singh, M. J. Dawson, and P. Manning, 1981. *Journal of Applied Behavior Analysis, 38*, p. 524. Reproduced with permission of John Wiley & Sons Inc.

the student had not asked a question during a preceding minimum of 5 minutes. This spaced-responding DRL intervention could decrease, yet not eliminate, asking questions.

Guidelines for Using DRL

Several factors influence the effectiveness of the three DRL schedules in diminishing problem behaviors. The following guidelines address those factors.

Choose the Most Appropriate DRL Procedure

Full-session, interval, and spaced-responding DRL schedules provide different levels of reinforcement for learners. Of the three DRL procedures, only spaced-responding DRL delivers reinforcement immediately following the occurrence of specific response; a response must be emitted following a minimum IRT before reinforcement. Practitioners use spaced-responding DRL to reduce the occurrences of a behavior while maintaining those behaviors at lower rates.

With full-session and interval DRL, a response does not need to occur for the participant to receive the reinforcer. Practitioners may apply full-session or interval DRL when it is acceptable that the rate of the problem behavior reaches zero or as an initial step toward the goal of eliminating the behavior.

Spaced-responding and interval DRL usually produce reinforcement at a higher rate than full-session DRL does. Arranging frequent contact with the reinforcement contingency is especially appropriate, and most often necessary, for learners with severe problem behaviors.

Recognize the Limitations of DRL

If a practitioner needs to reduce an inappropriate behavior quickly, DRL would not be the method of first choice. Reducing the inappropriate behavior to appropriate levels with DRL may take more time than the practitioner can afford. Further, DRL should not be used with self-injurious, violent, or potentially dangerous behaviors. Finally, from a practical standpoint, using DRL means that the practitioner must focus on the inappropriate behavior. If a teacher, for example, is not cautious, he may unintentionally give too much attention to the inappropriate behavior, inadvertently reinforcing it.

Effective application of interval DRL and spaced-responding DRL procedures requires continuous monitoring of problem behavior, careful timing, and frequent reinforcement. Without the help of an assistant, practitioners may have difficulty applying the interval DRL procedure in group settings. Interval and spaced-responding DRL procedures are quite reasonable for one-on-one instruction or when competent assistance is available. Jessel and Borrero (2014) offer guidance for the selection and application of DRL schedules.

> Evaluation and implementation of spaced-responding DRL and full-session DRL should be considered in the context of clinical or research goals. The more effortful approach (spaced responding DRL) may be required when the goal is to sustain responding, albeit at rates lower than those produced under baseline conditions (e.g., applications to rapid eating, excessive hand raising, or tattling). In addition, the limitations of using spaced-responding DRL schedules (e.g., requires individual timers for each student to be reset following responding below the programmed IRT) may be assuaged when considering the possibility of the use of widespread technology such as tablets in classroom settings. Applications could be created on tablets with which teachers could select the IRT for each student immediately before the start of classroom activities. The teacher would only have to click on the child's name after each response to determine whether or not he or she met the criteria for reinforcer presentation. (p. 321)

Use Baseline Data to Guide the Selection of the Initial Response or IRT Limits

Practitioners can use the mean number of responses emitted during baseline sessions, or slightly lower than that average, as the initial full-session DRL criterion. For example, 8, 13, 10, 7, and 12 responses recorded per session over five baseline sessions equals a mean of 10 responses per session. Therefore, a limit of 8 to 10 responses per session would be an appropriate initial full-session DRL criterion.

Interval DRL and spaced-responding DRL initial time criteria can be set at the baseline mean or slightly lower. For example, 1 response per 15 minutes makes an acceptable initial interval DRL criterion, as calculated from a baseline mean of 4 responses per 60-min session. With the same baseline data (i.e., 4 responses per 60-min session), it appears reasonable to use 15 minutes as the initial IRT criterion for a spaced-responding DRL schedule. That is, a response will produce reinforcement only if it is separated from the prior response by a minimum of 15 minutes.

Gradually Thin the DRL Schedule

Practitioners should gradually thin the DRL schedule to achieve the desired final rate of responding. Practitioners commonly use three procedures for thinning the initial DRL time criterion.

1. *With full-session DRL*, the practitioner can set a new DRL criterion using the participant's current DRL performances. Another option is to set a new DRL criterion at slightly less than the mean number of responses emitted during recent DRL sessions.
2. *With interval DRL*, the practitioner can gradually decrease the number of responses per interval if the current criterion is more than one response per interval; or, gradually increase the duration of the criterion interval if the current criterion is one response per interval.
3. *With spaced-responding DRL*, the practitioner can adjust the IRT criterion based on the mean IRT of recent sessions, or slightly less than that average. For example, Wright and Vollmer (2002) set the IRT for the DRL component of a treatment package that successfully reduced the rapid eating of a 17-year-old girl at the mean IRT of the previous five sessions. The researchers did not exceed an IRT of 15 seconds because it was not necessary to reduce the girl's eating below a rate of four bites per minute.

Practitioners who successfully thin DRL schedules of reinforcement make gradual, but systematic, changes in time and response criteria associated with full, interval, and space-responding DRL variations.

Two possible decision rules for thinning the DRL schedule are as follows:

> ***Rule 1:*** Practitioners may want to change the DRL criterion whenever the learner meets or exceeds the criterion for three consecutive sessions.
>
> ***Rule 2:*** Practitioners may want to change the DRL criterion whenever the learner receives reinforcement for at least 90% of the opportunities for three consecutive sessions.

Provide Feedback

The effectiveness of a DRL procedure can be enhanced by feedback to help the learner monitor her rate of responding. Full-session, interval, and spaced-responding DRL procedures provide different levels of feedback for participants. The most accurate feedback comes with spaced-responding DRL because reinforcement follows each response that meets the IRT criterion. When a response occurs that does not meet the IRT criterion, reinforcement is withheld, the time interval is immediately reset, and a new interval begins. This process provides learners with immediate feedback on responding per interval.

Interval DRL also provides a high level of feedback, although it is less than that of spaced-responding DRL. Interval DRL provides the learner with two types of feedback. The first problem behavior does not provide feedback. The second response, however, resets the time interval, providing a consequence for the problem behavior. Reinforcement occurs at the end of the interval when one or no problem behaviors occurred during the interval. These two types of feedback improve the effectiveness of the interval DRL intervention (Deitz et al., 1978).

Applied behavior analysts can arrange full-session DRL with or without feedback. The usual arrangement does not provide feedback concerning moment-to-moment accumulation of responses. Deitz (1977) stated that with full-session DRL, learners would respond only to the DRL criterion: Once the learner loses the opportunity for reinforcement during the session, he could then emit high rates of misbehavior without consequence. When the schedule is arranged without moment-to-moment feedback, learners usually stay well below the DRL limit. Full-session DRL, without moment-to-moment feedback, may not be as effective for learners with severe problem behaviors as spaced-responding and interval DRL. The effectiveness of full-session DRL relies heavily on an initial verbal description of the contingencies of reinforcement (Deitz, 1977).

SUMMARY

Differential Reinforcement Defined

1. Differential reinforcement entails reinforcing one response class and withholding reinforcement for another response class.

2. When used as a reductive procedure for problem behavior, differential reinforcement consists of (a) providing reinforcement contingent on a behavior other than the problem behavior (or the problem behavior occurring at a reduced rate) and (b) withholding reinforcement as much as possible for the problem behavior.

Differential Reinforcement of Alternative Behavior (DRA)

3. A practitioner applying DRA reinforces occurrences of a desirable alternative to the problem behavior and withholds reinforcement for the problem behavior.

4. DRA can be conceptualized as a concurrent schedule of reinforcement in which two response classes receive reinforcement at different rates: (a) the alternative behavior on a dense schedule of high-quality reinforcement and (b) the problem behavior on extinction or a very lean schedule of reinforcement.

5. The learner allocates more responding to the alternative behavior and less responding to the problem behavior, as described by the matching law.

6. When DRA entails reinforcing a behavior that cannot occur simultaneously with the problem behavior, the procedure is sometimes called differential reinforcement of incompatible behavior (DRI).

7. When using DRA, practitioners should:
   - Select alternative behaviors that are present in the learner's repertoire, that require equal or less effort than the problem behavior, that are being emitted prior to intervention with sufficient frequency to provide opportunities for reinforcement, and that are likely to produce reinforcement when the intervention ends.
   - Select potent reinforcers that can be delivered when the alternative behavior occurs and withheld following instances of the problem behavior. The consequences that maintain the problem behavior can function as a reinforcer for the alternative behavior.
   - Reinforce the alternative behavior on a continuous reinforcement schedule initially and then gradually thin the schedule of reinforcement.
   - Be alert to increased occurrences of the problem behavior when treatment shifts from a clinical to a natural setting, when new therapists and/or caregivers begin working with the client, and when the reinforcement schedule for the alternative behavior is thinned to levels that can be maintained in the client's everyday environment.
   - Combine DRA with other reductive procedures to produce a more potent intervention.

Differential Reinforcement of Other Behavior (DRO)

8. A practitioner applying DRO delivers reinforcers contingent on the problem behavior not occurring throughout intervals of time (interval DRO) or at specific moments of time (momentary DRO).

9. With interval DRO, the omission of the problem behavior throughout a predetermined time interval produces reinforcement, and any instance of the problem behavior during the interval resets the interval and postpones reinforcement.

10. With momentary DRO, absence of the problem behavior at predetermined moments in time produces reinforcement; instances of the target behavior at other points in time do not alter when the next opportunity for reinforcement becomes available.

11. Availability of reinforcement with interval and momentary DRO procedures can occur on fixed- or variable-time schedules.

12. When using DRO, practitioners should:
    - Establish an initial DRO time interval that ensures the learner's current level of behavior will produce frequent reinforcement when the DRO contingency is applied.
    - Be careful not to reinforce inadvertently other inappropriate behaviors.
    - Deliver reinforcement at the intervals or moments in time specified by the DRO schedule contingent on the absence of the problem behavior *and* the absence of any other significant inappropriate behaviors.
    - Increase the DRO interval gradually based on decreases in the problem behavior.
    - Extend DRO in other settings and times of day after the problem behavior is substantially reduced in the treatment setting.
    - Combine DRO with other reductive procedures.

Differential Reinforcement of Low Rates of Responding (DRL)

13. A practitioner applying DRL delivers reinforcement (a) following each occurrence of the target behavior that is separated from the previous response by a minimum amount of time or (b) contingent on the number of responses within a period not exceeding a predetermined criterion.

14. DRL is used to decrease the rate of a behavior that occurs too frequently, but not to eliminate the behavior entirely.

15. Reinforcement on a full-session DRL schedule is delivered when responding during an entire instructional or treatment session is equal to or below a criterion limit.

16. On an interval DRL schedule of reinforcement, the practitioner divides the total session into a series of equal intervals of time and provides reinforcement at the end of each interval in which the number of responses was equal to or below a criterion limit.

17. Reinforcement on a spaced-responding DRL schedule follows each occurrence of the target behavior that is separated from the previous response by a minimum interresponse time (IRT).

18. When using DRL, practitioners should:
    - Not use DRL if a problem behavior needs to be reduced quickly.
    - Not use DRL with self-injurious or other violent behaviors.
    - Select the most appropriate DRL schedules: full-session or interval DRL when it is acceptable that the rate of the problem behavior reaches zero or as an initial step toward the goal of eliminating the behavior; spaced-responding DRL for reducing the rate of a behavior to be maintained in the learner's repertoire.
    - Use baseline data to guide the selection of the initial response or IRT limits.
    - Thin the DRL schedule gradually to achieve the desired final rate of responding.
    - Provide feedback to help the learner monitor the rate of responding.

KEY TERMS

differential reinforcement of alternative behavior (DRA)
differential reinforcement of incompatible behavior (DRI)
differential reinforcement of low rates (DRL)
differential reinforcement of other behavior (DRO)
fixed-interval DRO (FI-DRO)
fixed-momentary DRO (FM-DRO)
full-session DRL
interval DRL
spaced-responding DRL
variable-interval DRO (VI-DRO)
variable-momentary DRO (VM-DRO)

MULTIPLE-CHOICE QUESTIONS

1. Joni works in a group home, with a group of men with disabilities. She has a good relationship with each of the men, but one of the residents continues to make sexually-inappropriate comments to her. Joni typically replies, "Frank, stop calling me that! You know I don't like it and it's not appropriate," as she turns red in the face. An informal functional behavior assessment indicates this behavior is maintained by Joni's attention. The group home staff decides to implement a DRA intervention. Which of the following would be an appropriate example of DRA in this case?
   - **a.** Providing enthusiastic attention whenever Frank says anything appropriate to Joni, while ignoring him if he makes inappropriate remarks
   - **b.** Providing enthusiastic attention whenever Frank makes an appropriate greeting to Joni (such as "You look nice today, Joni."), while ignoring Frank if he uses inappropriate greetings
   - **c.** Providing increased enthusiastic attention to Frank throughout the day
   - **d.** Ignoring all of Frank's inappropriate verbalizations

   Hint: (See "Differential Reinforcement Defined")

2. Differential reinforcement always includes which two principles of behavior?
   - **a.** Reinforcement and punishment
   - **b.** Reinforcement and stimulus control
   - **c.** Reinforcement and extinction
   - **d.** Positive and negative reinforcement

   Hint: (See "Differential Reinforcement Defined")

3. In DRA, a practitioner:
   - **a.** Reinforces a desirable alternative to the problem behavior
   - **b.** Places the problem behavior on extinction
   - **c.** May choose to reinforce a behavior that is incompatible with the problem behavior
   - **d.** All of these are correct

   Hint: (See "Differential Reinforcement of Alternative Behavior")

4. The behavior selected as an alternative behavior in a DRA:
   - **a.** Should already be in the learner's repertoire
   - **b.** Should require more effort than the problem behavior
   - **c.** Should be emitted at a very low rate prior to intervention
   - **d.** Should require extensive training for practitioners to learn how to reinforce it

   Hint: (See "Differential Reinforcement of Alternative Behavior")

5. DRO interventions:
   - **a.** Provide reinforcement for a specific alternative behavior
   - **b.** Provide reinforcement for slowly increasing occurrences of a behavior
   - **c.** Provide reinforcement for incompatible behaviors
   - **d.** Provide reinforcement for not responding

   Hint: (See "Differential Reinforcement of Other Behavior")

6. A limitation of DRO is:
   - **a.** Other inappropriate behaviors may be reinforced accidentally
   - **b.** One may accidentally punish all responding in the individual.
   - **c.** It often produces an extinction burst effect.
   - **d.** The effects have been shown to be slow and gradual.

   Hint: (See "Differential Reinforcement of Other Behavior")

7. A DRL intervention is useful when the practitioner wants to:
   - **a.** Get rid of a target behavior all together
   - **b.** Teach a new response to replace the problem behavior
   - **c.** Decrease the overall rate of a problem behavior, but not get rid of it all together
   - **d.** Increase the overall rate of a target behavior

   Hint: (See "Differential Reinforcement of Low Rates of Responding")

8. If the mean interresponse time (IRT) of a target problem behavior is 12 responses per hour, and you are implementing a DRL procedure, what should the initial DRL criterion be?
   - **a.** More than 12 responses per hour
   - **b.** No more than 11 responses per hour
   - **c.** No more than 1 response per hour
   - **d.** No more than 4 responses per hour

   Hint: (See "Differential Reinforcement of Low Rates of Responding")

ESSAY-TYPE QUESTIONS

1. The introduction to this chapter states that the procedures described in this chapter are reinforcement-based procedures for decreasing problem behavior. But, doesn't any reinforcement-based procedure, by definition, increase a target behavior and not decrease a target behavior? Explain how a differential reinforcement procedure can be used to decrease a target behavior.

   Hint: (See "Differential Reinforcement Defined")

2. When implementing a DRA intervention, it is useful to select reinforcers that are powerful and can be delivered consistently. Explain the importance of selecting reinforcers for such interventions, and explain the best method for selecting reinforcers for such interventions.

   Hint: (See "Differential Reinforcement of of Alternative Behavior")

3. Explain the difference between a momentary and interval DRO and when you might use each.

   Hint: (See "Differential Reinforcement of Other Behavior")

4. Explain the difference between full-session, interval, and spaced-responding DRL and when you might use each.

   Hint: (See "Differential Reinforcement of Low Rates of Responding")

NOTES

1. Differential reinforcement is also used to increase desired behavior, as in the differential reinforcement of high rates (DRH) (see Chapter 13) and shaping (see Chapter 22). Various forms of differential reinforcement contingencies are also used as experimental control procedures (see Chapter 8 and Thompson & Iwata, 2005).
2. DRA is a primary component of *functional communication training (FCT)*, an intervention in which the alternative behavior serves the same communicative function as the problem behavior (e.g., saying "Break, please" results in the same reinforcement as aggression or tantrums did previously). FCT is described in detail in Chapter 26.
3. Because instances of target problem behavior in DRO and DRL (to be discussed later in this chapter) often postpone reinforcement, some behavior analysts conceptualize DRO and DRL as negative punishment procedures rather than reinforcement techniques. For example, Van Houten and Rolider (1990) consider DRO and DRL variations of a procedure they called *contingent reinforcement postponement*.
4. DRO can also be applied using data from permanent product measurement. For example, Alberto and Troutman (2013) described a procedure in which a teacher provided reinforcement each time a student submitted a paper that contained no doodles. If the papers were basically of the same length or type, the procedure would be a variation of the fixed-interval DRO.
5. Hammond and colleagues (2011) reported several examples of different signals used with FM-DRO: *turning away, prompts,* and *praise* (Harris & Wolchik, 1979), *gesture* (Repp, Barton, & Brulle, 1983), *tone* (Conyers, Miltenberger, Romaniuk, Kopp, & Himle, 2003), and *music* (Sisson, Van Hasselt, Hersen, & Aurand, 1988).
6. Because reinforcement in a spaced-responding DRL immediately follows an instance of the target behavior, it is the applied variation of DRL that most closely resembles the DRL schedules of reinforcement described by Ferster and Skinner (1957).

CHAPTER 26

Antecedent Interventions

LEARNING OBJECTIVES

- Define and discuss applications of antecedent interventions.
- Define and discuss applications of noncontingent reinforcement.
- Define and discuss applications of high-probability request sequences.
- Define and discuss applications of functional communication training.

The owner of a private elementary school decided to dedicate her school to the applications of direct instruction, precision teaching, and behavior analysis. The school served students with mild to moderate intellectual disabilities, learning disabilities, and problem behaviors. To assist with the school's change of focus, the owner contacted a professor at a local university with expertise in applied behavior analysis to conduct weekly after-school in-service trainings for her teachers. The school's owner wanted the in-services to concentrate on (a) principles of behavior, (b) measurement and analysis, and (c) strategies and tactics for application.

The in-service progressed well. The teachers developed a school-wide token economy that included a store where students could exchange their tokens based on their performance. However, the teachers reported a growing problem during recess—four boys were hitting and shoving other students.

In subsequent discussions with the teachers, several intervention approaches were presented, including response cost or time-out, to address the inappropriate playground behavior. One teacher made this suggestion.

Let's not use punishment with these boys. I suggest we develop a playground safety patrol, with the four boys serving as the patrol officers, and expand the use of token economy during recess. We could meet with the boys, tell them about the new safety patrol, and that they have been selected to serve as the first patrol officers. Then, we give them their safety patrol badges to wear. We will need to teach the new officers (a) how to identify good playground behavior—we can describe examples of good playground behavior, and role-play this playground behavior; (b) how to praise good playground behavior; and, finally, (c) how to present tokens for good playground behavior of other children during recess.

The group embraced this option and implemented it. Within 2 weeks of implementation, inappropriate playground behavior decreased, and the teachers gradually faded out the presence of the playground safety patrol.

Anecdotally, the teachers reported that whereas the four boys did not have many positive playground interactions with other students before the antecedent intervention, they appeared to be making friends on the playground subsequent to it.

In the early days of applied behavior analysis, researchers and practitioners emphasized the three-term contingency: how consequences affect behavior and how differential consequences produce stimulus discrimination and stimulus control. Seldom did applied behavior analysts attempt to change behavior by manipulating antecedent events. This situation changed dramatically following three groundbreaking publications in the 1980s: Jack Michael's (1982) conceptual analysis of establishing operations; Brian Iwata and colleagues' demonstration of a method to assess functional relations between self-injury and specific antecedent events (Iwata, Dorsey, Slifer, Bauman, & Richman, 1982); and Ted Carr and Mark Durand's (1985) experiment showing that teaching children to emit an appropriate communicative response during conditions that previously occasioned disruptive behavior reduced misbehavior to near zero. Building upon the concepts and techniques introduced in these discipline-altering articles, behavior analysts have developed a wide array of antecedent interventions that diminish problem behaviors and promote adaptive behaviors in social, academic, leisure, and work environments.

DEFINING AND CLASSIFYING ANTECEDENT INTERVENTIONS

An **antecedent intervention** is implemented *prior to* and *independent of* the target behavior's occurrence. Some antecedent interventions manipulate motivational variables, some make the target behavior more or less effortful, some entail training an alternative behavior, some include differential consequences for responding, and some change the environment such that the opportunities to engage in a problem behavior are restricted (or,

conversely, opportunities made more prevalent for a desired behavior). Table 26.1 shows a sampling of antecedent interventions practitioners might use to address common behavior problems and promote positive behavior.

Although identifying such varied interventions with a single term is economical, recognizing the basic principles at the heart of each intervention is the first step toward effective application. Antecedent interventions based on stimulus control (discriminative stimuli [S^Ds]) evoke behavior because they have been correlated with increased availability of reinforcement. The evocative function of motivating operations (MOs), however, is independent of the differential availability of reinforcement. For example, an establishing operation will increase the current rate of certain types of behavior even when an effective reinforcer is not available. Failure to distinguish the different functions of antecedent events leads to conceptual confusion and ineffective, or possibly even unethical, service to clients.

In addition to improved conceptual clarity and consistency, understanding the different reasons for the evocative functions of S^Ds and MOs has important applied implications. Antecedent treatments involving stimulus control must include manipulating the differential availability of reinforcement in the presence and absence of the S^D. Behavior change strategies based on motivating operations must change antecedent events. Understanding these differences may improve the development of more effective and efficient behavior change efforts involving antecedent events.

Classifying Antecedent Interventions

Antecedent interventions can be classified in several ways. For example, Smith (2011) identified two broad categories of antecedent interventions for problem behavior. "*Function-based antecedent interventions* directly manipulate at least one component of a particular operant contingency that has been identified to maintain the problem behavior" (p. 297). With this definition, antecedent interventions based on stimulus control and those that involve motivating operations would be considered function-based. Smith classified antecedent-based interventions "whose effects do not depend on specific identification of the variables that set the occasion for and maintain the problem behavior" as *default interventions* (p. 297).

Antecedent interventions can also be classified by whether or not differential consequences are required for behavior change. The effects of a *contingency-dependent* antecedent intervention depend on differential consequences for the target behavior (or alternative behavior) in the presence or absence of the antecedent. Antecedent interventions based on stimulus control are contingency dependent. For example, in the presence of 2 + 2 = ?, a student responds 4, not because of the stimulus 2 + 2 = ?, but because of a past reinforcement history for saying 4, including perhaps a history of non-reinforcement for responses other than 4. Chapter 17 addresses contingency-dependent antecedent interventions based on stimulus control.

The effects of a *contingency-independent* antecedent intervention do not depend on differential consequences for the target behavior. Smith's (2011) default antecedent interventions are contingency independent, as are antecedent interventions based on motivating operations. The evocative and abative effects of establishing and abolishing operations occur independent of differential consequences (see Chapter 16). Table 26.2 provides examples of abolishing operations to decrease the effectiveness of the reinforcer maintaining various problem behaviors and a corresponding reduction of those behaviors. Chapter 16 discusses motivating operations to effect behavior change.

Smith and Iwata (1997) remind us that the effects of MOs are temporary and may not produce permanent improvements in behavior. However, practitioners can supplement MO manipulations with extinction and differential reinforcement to change behavior on a more permanent basis (Phillips, Iannaccone, Rooker, & Hagopian, 2017).

The next sections of this chapter describe three contingency-independent antecedent interventions with established scientific evidence of their effectiveness: noncontingent reinforcement, high-probability instructional sequence, and functional communication training. The chapter closes with brief descriptions of three default antecedent interventions: restraint, enriched environment, and antecedent exercise.

TABLE 26.1 Examples of Challenging Behavior and Antecedent Interventions That Might Address Them

Challenging Behavior Situation	Antecedent Intervention
When directed to do homework or take a bath, the child is noncompliant.	Parents provide a choice: "Do you want to do your homework first or take a bath first?"
When requested to complete a math worksheet with 25 problems, student disrupts class.	Teacher breaks 25 problems into 5 worksheets of 5 problems each.
After entering the classroom and waiting for the first lesson to begin, several students misbehave.	Teacher pins an index card for each student on the bulletin board. Each card contains a personalized question. Upon entering the classroom, students remove their cards from the bulletin board, go to their desks, and write an answer on the card.
After staying on task for several minutes, a nonvocal verbal employee terminates the work activity by crying and throwing materials to the floor.	Supervisor teaches the employee to sign "Break please" when tired or frustrated, and provides a brief break when the employee does so.
While creeping and crawling around the house, an infant may encounter many potentially dangerous events.	Attach gates to stairways, plug electrical outlets, put locks on cabinet doors, and remove table lamps.

TABLE 26.2 Examples of Antecedent Interventions Using Abolishing Operations

Abolishing Operation	Example
Provide corrective prompts as an antecedent event.	Antecedent corrective academic prompts reduced destructive behavior to zero (Ebanks & Fisher, 2003).
Provide presession exposure to stimuli that function as reinforcers.	A father–son playtime preceding compliance sessions improved son's compliance with father's requests (Ducharme & Rushford, 2001).
Provide free access to leisure activities.	Manipulation of leisure items effectively competed with self-injurious behavior (SIB) maintained by automatic reinforcement (Lindberg, Iwata, Roscoe, Worsdell, & Hanley, 2003).
Reduce noise levels.	Reducing noise levels decreased stereotypic covering of ears with hands (Tang, Kennedy, Koppekin, & Caruso, 2002).
Change levels of social proximity.	Low levels of distant proximity reduced aggressive behaviors (Oliver, Oxener, Hearn, & Hall, 2001).
Offer choices.	Escape-maintained problem behaviors decreased when students had opportunities to choose among tasks (Romaniuk et al., 2002).
Increasing response effort.	Increasing response effort for pica produced reductions in pica (Piazza, Roane, Kenney, Boney, & Abt, 2002).

NONCONTINGENT REINFORCEMENT

Noncontingent reinforcement (NCR) is an antecedent intervention in which stimuli with known reinforcing properties are delivered on a fixed-time (FT) or variable-time (VT) schedule independent of the learner's behavior.[1] Noncontingent reinforcement may effectively diminish difficult-to-manage behaviors because the reinforcers that maintain the behavior are available freely and frequently, thereby functioning as an abolishing operation (AO) that reduces the motivation to engage in the behavior. NCR is an important and effective antecedent intervention for the treatment of severe problem behavior displayed by persons with intellectual and/or developmental disabilities (Phillips et al., 2017).

A functional analysis of the reinforcing contingency maintaining the problem behavior determines whether NCR is implemented with positive reinforcement, negative reinforcement (escape), or automatic reinforcement.

NCR with Positive Reinforcement

Kahng, Iwata, Thompson, and Hanley (2000) provided an excellent example of applying NCR with positive reinforcement. A functional analysis showed that social-positive reinforcement maintained self-injurious behavior (SIB) or aggression in three adults with developmental disabilities. During baseline, each occurrence of SIB or aggression produced attention for two of the adults and a small bit of food for the third adult. During the initial sessions of NCR, the adults received attention or small bits of food on an initial fixed-time (FT) schedule (e.g., 5 seconds). Later, the schedule was thinned to a terminal criterion of 300 seconds. Figure 26.1 presents the baseline and NCR performances of the three participants and shows that the NCR procedure effectively decreased occurrences of SIB and aggression.

NCR Escape

Kodak, Miltenberger, and Romaniuk (2003) analyzed the effects of NCR escape on the instructional task compliance and problem behaviors of Andy and John, 4-year-old boys with autism. Andy's task was to point to cards with teacher-specified pictures, words, or letters on them. John used a marker to trace each letter of written words. Problem behaviors included resisting prompts, throwing materials, and hitting. During baseline, the therapist gave an instruction for task engagement and, contingent on problem behavior following the instruction, removed the task materials and turned away from the child for 10 seconds. During the NCR escape condition, the therapist used an initial FT 10-sec schedule for escape, meaning that the student had a break from the instructional requests every 10 seconds of the session. The initial 10-sec FT schedule was thinned each time the boy achieved a criterion for two consecutive sessions: 10 seconds to 20 seconds, to 30 seconds, to 1 minute, to 1.5 minutes, and finally to a terminal criterion of 2 minutes. The NCR escape procedure increased compliance and decreased problem behaviors.

NCR with Automatic Reinforcement

Lindberg, Iwata, Roscoe, Worsdell, and Hanley (2003) used NCR as a treatment to decrease the self-injurious behavior (SIB) of two women with profound intellectual disability. A functional analysis documented that automatic reinforcement maintained their SIB. The NCR procedure provided Julie and Laura with free access to a variety of home-based, highly preferred leisure items (e.g., beads, string) that they could manipulate throughout the day. Figure 26.2 shows that NCR object manipulation of preferred leisure items effectively diminished SIB, and the effects were maintained up to a year later. This experiment is important because it showed that NCR object manipulation could compete with automatic reinforcement to reduce the occurrence of SIB. However, treating problem behaviors maintained by automatic reinforcement often will require adding other treatments (e.g., response blocking) to accomplish clinically important effects (Phillips et al., 2017).

Using NCR Effectively

The following procedural recommendations identify three key elements for enhancing the effectiveness of NCR. (a) The

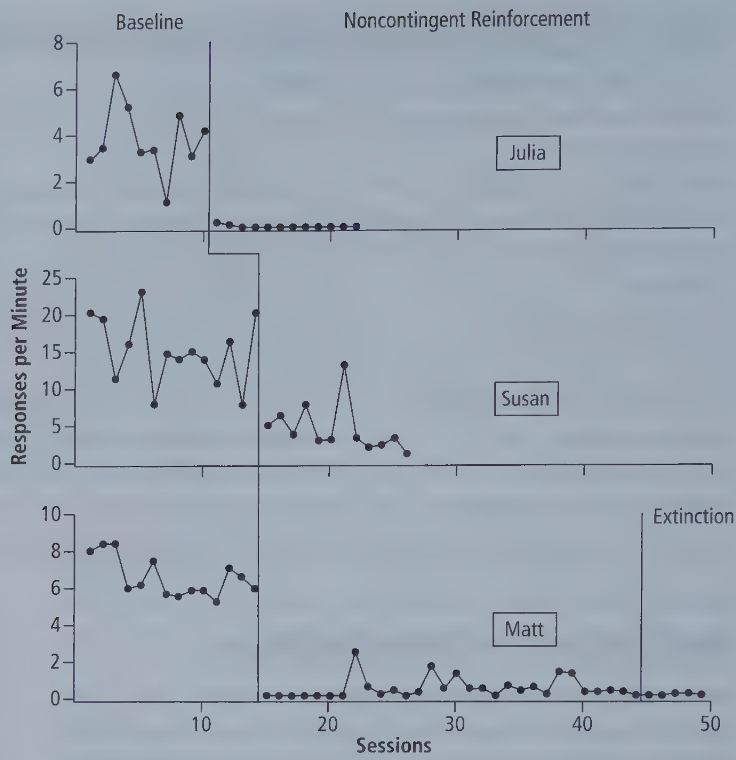

Figure 26.1 Number of SIB or aggressive responses per minute during baseline and NCR by three adults with developmental disabilities.

From "Treatment Efficacy of Noncontingent Reinforcement During Brief and Extended Application," by J. S. Lindberg, B. A. Iwata, E. M. Roscoe, A. S. Worsdell, and G. P. Hanley, 2003, *Journal of Applied Behavior Analysis*, *36*, p. 14. Copyright 2003 by the Society for the Experimental Analysis of Behavior. Reproduced by permission.

amount and quality of stimuli with known reinforcing properties influence the effectiveness of NCR. (b) Most treatments include extinction with NCR interventions. (c) Reinforcer preferences can change during intervention. That is, the NCR stimuli may not continue competing with the reinforcers that maintain the problem behavior. DeLeon, Anders, Rodriguez-Catter, and Neider (2000) recommended periodically using a variety of available stimuli with the NCR intervention to reduce problems of changing preferences.

Functional Behavior Assessment

The effectiveness of using NCR depends on the correct identification of the positive, negative, or automatic reinforcers maintaining the problem behavior. Advances in conducting

functional behavior assessments have greatly improved the effectiveness of NCR by accurately pinpointing the contingencies maintaining the behavior.[2]

Emphasizing NCR

Applied behavior analysts can enhance the effectiveness of an NCR intervention by increasing the number of known reinforcing stimuli over the non-NCR condition. For example, Ringdahl, Vollmer, Borrero, and Connell (2001) found that NCR was ineffective when the baseline condition and the NCR condition contained a similar number of reinforcers. NCR was effective, however, when the NCR schedule was denser than the baseline schedule. Applied behavior analysts can use the rates of reinforcement during baseline to establish an initial NCR schedule to ensure a discrepancy between baseline and NCR conditions.

Ringdahl and colleagues (2001) suggested three procedures for emphasizing reinforcement during the NCR intervention: (a) increase the delivery of stimuli with known reinforcing properties, (b) use a different schedule of reinforcement at treatment onset (e.g., continuous delivery or availability of stimuli with known reinforcing properties), and (c) combine differential reinforcement of other behavior (DRO) with the NCR treatment package. DRO will decrease the adventitious reinforcement of the problem behavior from the time-based NCR schedule.

Time-based NCR Schedules

Most applications of NCR use a fixed-time schedule (FT) for the delivery of stimuli with known reinforcing properties. A **fixed-time schedule** (FT) means that the interval of time for the presentation of these stimuli remains the same from delivery to delivery. When applied behavior analysts program the NCR time interval to vary across deliveries, it is called a **variable-time schedule** (VT). For example, an NCR VT schedule of 10 seconds means that, on the average, stimuli with known reinforcing properties are presented every 10 seconds. This VT schedule could use time intervals such as 5, 8, 10, 12, or 15 seconds, arranged to occur in random sequence to produce effective results (Carr, Kellum, & Chong, 2001).

Setting the initial NCR time schedule is an important aspect of the NCR procedure. The initial schedule can have an impact on the effectiveness of the intervention (Kahng, Iwata, DeLeon, & Wallace, 2000). Researchers consistently recommend an initial dense FT or VT schedule (e.g., Van Camp, Lerman, Kelley, Contrucci, & Vorndran, 2000). The therapist can set a dense time value (e.g., 4 seconds) arbitrarily. Usually, however, it is more effective to set the initial time value based on the number of occurrences of the problem behavior, which will ensure frequent contact with the NCR stimuli.

The following procedure can be used to determine an initial NCR schedule: Divide the total duration of all baseline sessions by the total number of occurrences of the problem behavior recorded during baseline, and set the initial interval at or slightly below the quotient. For example, if the participant emitted 300 aggressive acts during 5 days of the baseline, and each baseline session was 10 minutes in duration (i.e., 600 seconds), then 3000 seconds divided by 300 responses produces a quotient of 10 seconds. Accordingly, these baseline data suggest an initial FT interval of 7 to 10 seconds. Analysts then thin the schedule by adding small time increments to the NCR interval. However, thinning a time-based schedule is best begun only after the initial NCR interval has produced a reduction in the problem behavior.

Applied behavior analysts have used three procedures to thin NCR schedules: (a) constant time increase, (b) proportional time increase, and (c) session-to-session time increase or decrease (Hanley, Iwata, & Thompson, 2001; Van Camp et al., 2000). A therapist, for example, can increase the FT or VT schedule intervals by using a constant duration of time, and decrease the amount of time that the learner has access to the NCR stimuli by a constant time factor. So, a therapist might increase the schedule interval by 7 seconds at each opportunity, and each time decrease access to the stimuli by 3 seconds.

Likewise, a therapist can increase the FT or VT schedule intervals proportionately, meaning that each interval is increased by the same percentage of time. With this procedure, each time interval might be increased by 5%. If the initial time interval was 600 seconds, then the next interval would be 630 seconds ($5\% \times 600 = 30$ seconds; $600 + 30 = 630$ seconds) and so on.

Finally, a therapist can use the learner's performance to change the schedule interval on a session-to-session basis. For example, at the end of a session, the therapist establishes a new NCR time interval for the next session by dividing the number of problem behaviors that occurred in that session by the duration of the session and using that quotient as the next session's FT interval.

A therapist should adjust the interval if the problem behavior worsens during schedule thinning. The duration of the NCR interval can be readjusted after control of the problem behavior has been re-established. The readjustment, however, should proceed more gradually.

Setting Terminal Criteria

Applied behavior analysts usually select an arbitrary terminal criterion for NCR schedule thinning. Kahng and colleagues (2000) concede that research has not established a de facto terminal criterion for NCR schedule thinning. While a variety of time intervals have been used—3 minutes, 5 minutes, 10 minutes—it seems that a 5-min FT schedule has found the most favor in applied settings. The 5-min FT schedule seems to be both practical and effective.

Box 26.1 describes guidelines for using NCR in the classroom suggested by Coy and Kostewicz (2018).

Considerations for Using NCR

NCR makes an effective intervention. It has advantages in addition to effectiveness, and some disadvantages. Table 26.3 lists the advantages and disadvantages of using NCR.

BOX 26.1

Implementing NCR in the Classroom

1. *Establish context.* The first step involves using data collection and observation to identify and place a well-defined problem behavior in context. Definitions should avoid large categories of behavior and the absence of behavior, such as "off task," "disruptive," or "not listening." Behavioral definitions should include examples and nonexamples; for instance, calling out without permission includes all instances when the student yells or says something without being called on but does not include instances of choral responding. After defining the behavior, teachers then determine what commonly occurs before and after the target behavior. This contextual information provides better insight into why the behavior occurs. In addition to anecdotal or observational information, more formalized methods can provide a well-rounded picture of the target behavior. After determining the context surrounding the target behavior, teachers collect baseline data on the target behavior, collecting data at times when the behavior is most likely to occur. Typical types of data collection include (a) frequency (how many times the behavior occurs within a certain amount of time), (b) duration per occurrence (how long the behavior occurs), (c) latency (how long it takes for the behavior to initiate following a direction or request), or (d) interresponse time (IRT; time between the end of one instance of the behavior and the beginning of another).
2. *Identify potential reinforcers.* NCR relies on careful and purposeful use of positive reinforcers (e.g., items or events the student enjoys or will work for). The reinforcer should match the common consequence for the target behavior. Using a functional reinforcer (such as a break from task demands for escape-maintained behaviors or praise for attention-seeking behaviors) gives NCR the greatest chance of success.
3. *Deliver reinforcers.* During NCR, the functional reinforcer should be provided on a continuous basis and not in response to the occurrence of the target behavior. Teachers enrich the environment by providing reinforcement more often than the student currently receives for the problem behavior.
4. *Finalize the plan.* Any formal behavioral intervention must be well organized prior to implementation. Written behavior plans include background information, current levels of performance, implementation guidance, and monitoring or evaluation sections. NCR interventions maintain the same requirements.
5. *Implement and evaluate.* After reviewing the student's baseline behavior data and completing the NCR Planning Worksheet, it is time to put the plan into action. Practitioners implementing NCR must follow the schedule closely and carefully. Electronic technologies (e.g., cell phone applications) can assist with the implementation of NCR. Teachers should be aware of a few considerations when implementing NCR. The student may engage in the problem behavior just before the end of an interval. Instead of immediately providing the reinforcer, withhold the presentation of the reinforcer for approximately 10 seconds or until the student no longer displays the target problem behavior. Once the reinforcer is provided, the next NCR interval starts. Practitioners should also be prepared for brief escalations in the problem behavior during NCR. The teacher monitors yet ignores these escalations and provides the reinforcer according to the current schedule of reinforcement.

Adapted from "Noncontingent Reinforcement: Enriching the Classroom Environment to Reduce Problem Behaviors," by J. N. Coy and D. E. Kostewicz, 2018, *Teaching Exceptional Children*, *50*, 301–309. Copyright 2018 by Council for Exceptional Children. Used by permission.

TABLE 26.3 Possible Advantages and Disadvantages of Noncontingent Reinforcement

Advantages

- NCR is easier to apply than positive reductive techniques that require monitoring the client's behavior for the contingent delivery of the reinforcer (Phillips et al., 2017).
- NCR helps create a positive learning environment, which is always desirable during treatment.
- A package treatment that includes NCR with extinction may reduce extinction-induced response bursts (Van Camp et al., 2000).
- Chance pairings of appropriate behavior and NCR delivery of stimuli with known reinforcing properties could strengthen and maintain those desirable behaviors (Roscoe, Iwata, & Goh, 1998).

Disadvantages

- Free access to NCR stimuli may reduce motivation to engage in adaptive behavior.
- Chance pairings of problem behavior and NCR delivery of stimuli with known reinforcing properties could strengthen the problem behavior (Van Camp et al., 2000).
- NCR escape can disrupt the instructional process.

HIGH-PROBABILITY INSTRUCTIONAL SEQUENCE

Student compliance provides opportunities for the development of many important behaviors. Noncompliance, however, is a prevalent problem with persons who have developmental disabilities and behavior disorders. The high-probability instructional sequence is a nonaversive procedure for improving compliance and diminishing escape-maintained problem behaviors. The high-probability instructional sequence may decrease excessively slow responding to instructions and thereby reduce overall time for completing tasks (Mace et al., 1988).

When using a **high-probability instructional sequence (high-*p*)**, the practitioner presents two to five easy-to-follow instructions for which the participant has a history of compliance. When the learner complies with several high-*p* instructions in sequence, the practitioner immediately gives the target instruction (i.e., low-*p*). Engelmann and Colvin (1983) provided one of the first formal descriptions of the high-*p* instructional sequence in their compliance training procedure for managing severe behavior problems. They used the term *hard task* in the following dressing anecdote.

Typical Instructional Sequence

Teacher: "Please put on your shirt." (low-*p* request)

Student: Throws a tantrum to avoid or escape the hard task request.

Improved Instructional Sequence with Embedded High-*p* Instructional Sequence

Teacher: "Give me five!" (high-*p* request)

Student: Slaps teacher's outstretched hand appropriately.

Teacher: "All right, nice job! Now, take this ball and put it in your pocket." (high-*p* request)

Student: Puts the ball in pocket.

Teacher: "Great! That is right! Now, please put on the shirt." (low-*p* request)

Student: Puts on the shirt without the tantrum. (p. 13, text in parentheses added)

The reductive effects of the high-*p* instructional sequence on noncompliance resemble the abative effects of an AO that reduces the current potency of reinforcement for noncompliance with the low-probability requests (i.e., reducing the value of escape from requests). In effect, "[d]uring the high-*p* sequence, compliance with several high-*p* instructions, and receipt of reinforcement contingent upon this compliance, may therefore increase compliance with the subsequent low-*p* instruction" (Lipschultz & Wilder, 2017, p. 424). Some behavior analysts use **behavioral momentum** to describe a behavior's resistance to change following an alteration in reinforcement conditions, and the term is sometimes used to describe the effects produced by the high-*p* instructional sequence (Mace et al., 1988; Nevin, Mandell, & Atak, 1983).[3]

Research has demonstrated the high-*p* instructional sequence to be an effective treatment for a wide variety of behavior problems exhibited by participants ranging from preschoolers to adults, with and without disabilities. Behavioral improvements produced by the high-*p* instructional sequence have included compliance by preschoolers (Normand, Kestner, & Jessel, 2010; Wilder, Majdalany, Sturkie, & Smeltz, 2015), compliance by school-age students with teachers' academic instructions (Axelrod & Zank, 2012; Lee, Belfiore, Scheeler, Hua, & Smith, 2004), food acceptance by children with pediatric feeding disorders (Dawson et al., 2003; Ewry & Fryling, 2016; Patel et al., 2006), increased social interactions (Jung, Sainato, & Davis, 2008), and compliance with medical examination requests by children with autism (Riviere, Becquet, Peltret, Facon, & Darcheville, 2011).

Killu, Sainato, Davis, Ospelt, and Paul (1998) evaluated the effects of the high-*p* instructional sequence on compliant responding to low-*p* instructions and occurrences of problem behaviors by three preschool children with developmental delays. The researchers used a compliance criterion of 80% or higher for selecting high-*p* requests for two children and a 60% criterion for the third child. Compliance of less than 40% was used to select the low-*p* instructional.

The request sequence began with the experimenter or a trainer presenting three to five high-*p* requests. When a child complied with at least three consecutive high-*p* requests, a low-*p* request was immediately presented. Praise was provided immediately following each compliant response. Figure 26.3 shows the children's performances before, during, and after the high-*p* sequence. The sequence delivered by two different trainers increased compliant responding to the low-*p* requests of the three children. Compliant responding maintained across time and settings.

Using the High-*p* Instructional Sequence Effectively

Select High-p Instructions from Current Repertoire

The tasks selected for high-*p* instructions should be in the learner's current repertoire, occur regularly, and have a very short duration. Ardoin, Martens, and Wolfe (1999) selected high-*p* instructions by (a) creating a list of requests that corresponded to student compliance, (b) presenting each request on the list for five separate sessions, and (c) selecting as high-*p* requests only those tasks that the student complied with 100% of the time. A criterion of 80% compliance or greater for high-*p* instructions is commonly used (e.g., Belfiore, Basile, & Lee, 2008; Mace et al., 1988).

Axelrod and Zank (2012) empirically identified high-*p* and low-*p* instructions for Charles and Thomas, two fifth-grade students who emitted high rates of noncompliance and received special education services in a general education classroom. The students' teacher created a list of 40 typical classroom instructions and then presented each student each instruction 10 times randomly during reading and seatwork sessions over a period of 10 days. Instructions with 80% or greater compliance were categorized as high-*p*, and those with 40% compliance or less were categorized as low-*p*. Commands complied with between 40% and 80% of the

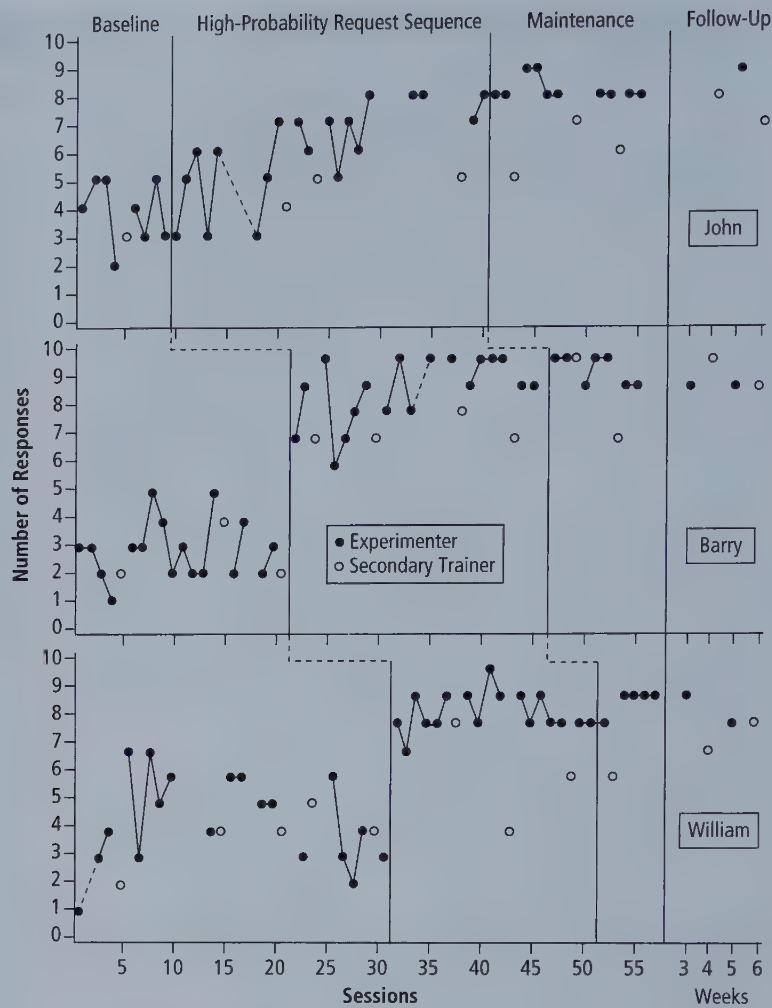

Figure 26.3 Number of compliant responses to low-probability requests delivered by the investigator and second trainer across sessions and conditions. Participants were given 10 low-*p* requests each session. Dashed lines indicate student absences.

From "Effects of High-probability Request Sequences on Preschoolers' Compliance and Disruptive Behavior," by K. Killu, D. M. Sainato, C. A. Davis, H. Ospelt, and J. N. Paul, 1998, *Journal of Behavioral Education, 8*, p. 358. Used by permission.

time were not used in the study. Table 26.4 shows Thomas' percentage compliance with teacher commands.

Mace (1996) reported that the effectiveness of the high-*p* sequence correlates with the number of increases in high-*p* requests. A high-*p* sequence with five requests may be more effective than a sequence with two requests; but the increase in effectiveness may have a trade-off in efficiency. For example, if the same, or nearly the same, effectiveness can be obtained with two or three high-*p* instructions as can be obtained with five or six, a teacher might select the shorter sequence because it is more efficient. When participants consistently comply with the low-*p* requests, the trainer should gradually reduce the number of high-*p* requests.

Present Requests Rapidly

The high-*p* requests should be presented in rapid succession, with short inter-request intervals. The first low-*p* request should immediately follow the reinforcer for high-*p* compliance (Davis & Reichle, 1996).

Acknowledge Compliance

The learner's compliance should be acknowledged immediately. Notice how the teacher in the previous dressing example acknowledged and praised the student's compliance ("All right, nice job!") before presenting the next request.

Use Potent Reinforcers

Individuals may emit aggression and self-injurious behaviors to escape from low-*p* request demands. Mace and Belfiore (1990) cautioned that social praise may not increase compliance if motivation for escape behavior is high. Therefore, high-quality positive stimuli immediately following compliance will increase the effectiveness of the high-*p* intervention.

Table 26.5 summarizes guidelines for using the high-*p* instructional sequence.

FUNCTIONAL COMMUNICATION TRAINING

Functional communication training (FCT) establishes an appropriate communicative behavior to compete with problem behaviors evoked by a motivating operation (MO). In contrast to NCR and the high-*p* instructional sequence that alter current MOs, FCT develops communicative behaviors that are sensitive to existing MOs. The practitioner uses differential reinforcement of alternative behavior (DRA) (see Chapter 25) to teach an adaptive response that produces the same reinforcer that has maintained the problem behavior, thereby making the alternative behavior functionally equivalent to the problem behavior. The alternative communicative responses can take many forms, such as vocalizations, signs, communication boards, word or picture

TABLE 26.4 Thomas' Percentage Compliance with Teacher Commands During Identification Period

Instruction Category	Instruction	Compliance During Identification Period (%)
High-*p*	Give teacher high five	100
	Give teacher fist pound	100
	Put hands on desk	90
	Pick up writing utensil (e.g., pencil, pen, color pencil)	90
	Put writing utensil in desk	80
	Put down writing utensil	80
	Put hands on lap	80
	Stand up	80
	Slide chair closer to desk	80
	Walk over to group	80
	Sit down with group	80
Low-*p*	Stop talking and continue working on assignment	10
	Put inappropriate materials (e.g., toy, drawing paper, color pencil box) in desk	10
	Stop talking and raise your hand	20
	Walk back to desk after unauthorized leave	20
	Read sentence or passage from text	30
	Write name on paper	30
	Begin working on assignment	30
	Take writing utensil out of mouth	30
	Walk over to the teacher's desk	40

Based on "Increasing Classroom Compliance: Using a High Probability Command Sequence with Noncompliant Students" by M. J. Axelrod and A. J. Zank, 2012, *Journal of Behavioral Education*, *21*, p. 125.

TABLE 26.5 Guidelines for Using the High-*p* Instructional Sequence

- Empirically identify high-*p* and low-*p* instructions before using the procedure. Compliance with high-*p* instructions should be 80% or greater; with low-*p*, 40% or less.
- Do not use the high-*p* request sequence just after an occurrence of the problem behavior. The student might learn that responding to a low-*p* request with the problem behavior will produce a series of easier requests.
- Present the high-*p* request sequence at the beginning and throughout the instructional period to reduce the possibility of problem behaviors producing reinforcement.
- Present high-*p* instructions rapidly, with brief intertrial intervals (1–5 sec) and reinforce compliance with each high-*p* instruction.
- If the participant does not comply with high-*p* instructions, stimuli associated with the low-*p* instruction should be identified and eliminated, or other high-*p* instructions should be used.
- Present first low-*p* instruction immediately following compliance with three to five high-*p* instructions.
- Present high-quality reinforcers for compliance with high-*p* instructions.
- Fade the ratio of high-*p* to low-*p* instructions to 1-to-1.
- Be alert to treatment drift in which practitioners present only high-*p* instructions to avoid escape-motivated aggression and self-injury evoked by low-*p* requests.
- If the procedure is ineffective, consider adding an extra intervention component.

(2003); Horner, Day, Sprague, O'Brien, and Heathfield (1991); Lipschultz and Wilder (2017); Mace (1996); Mace et al. (1988); Normand, Kestner, and Jessel (2010); Penrod, Gardella, and Fernand (2012); Pitts and Dymond (2012); and Wilder, Majdalany, Sturkie, and Smeltz (2015).

cards, vocal output systems, or gestures (Brown et al., 2000; Shirley, Iwata, Kahng, Mazaleski, & Lerman, 1997).

Carr and Durand (1985) described functional communication training as a two-step process: (1) conduct a functional behavior assessment to identify the stimuli with known reinforcing properties that maintain the problem behavior and (2) use those stimuli as reinforcers to develop an alternative behavior to replace the problem behavior. FCT is an effective treatment for many problem behaviors maintained by social attention.

FCT-based interventions typically involve several behavior change tactics in addition to teaching the alternative communicative response. For example, applied behavior analysts often use a combination of response prompting, time-out, physical restraint, response blocking, redirection, and extinction to address the difficult behavior.

Durand (1999) used FCT in school and community settings to reduce the challenging behaviors of five students with severe disabilities. Durand first completed functional behavior assessments to identify the objects and activities maintaining the problem behaviors. Following the functional assessments, the students learned to use a communication device that produced digitized speech to request objects and activities identified during the functional behavior assessments. The five students reduced the occurrences of their problem behaviors in school and community settings in which they used digitized speech to communicate. Figure 26.4 presents data on the percentage of intervals of problem behaviors occurring in community settings for each student. These data are socially significant because they show the importance of teaching skills that recruit reinforcement in natural settings, thereby promoting generalization and maintenance of intervention effects.

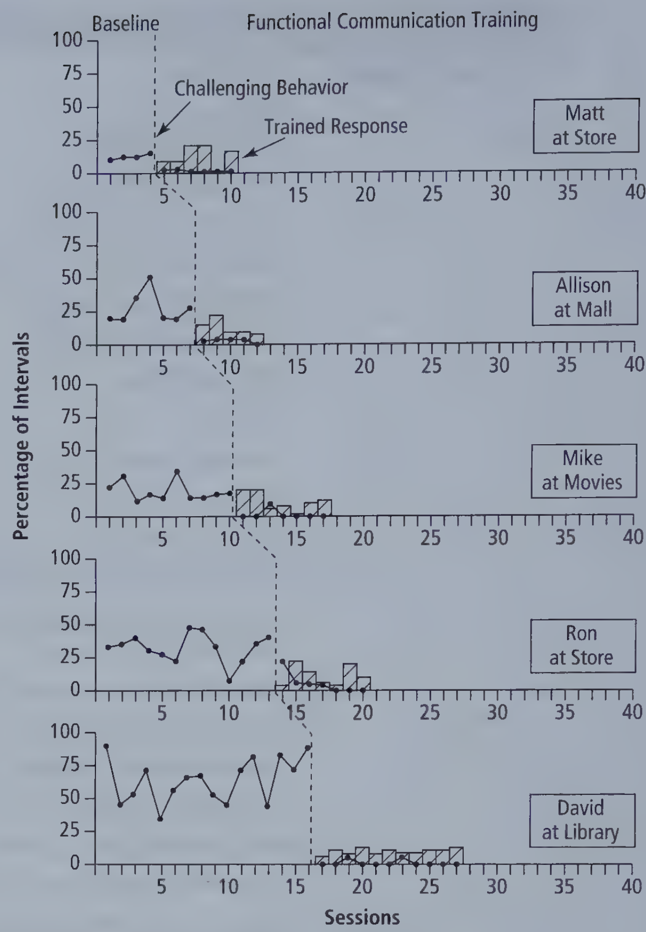

Figure 26.4 Percentage of intervals of challenging behavior by each of the five participants in baseline and FCT in community settings. The hatched bars show the percentage of intervals of unprompted communication by each student.

From "Functional Communication Training Using Assistive Devices: Recruiting Natural Communities of Reinforcement," by V. M. Durand, 1999, *Journal of Applied Behavior Analysis, 32,* p. 260. Copyright 1999 by the Society for Experimental Analysis of Behavior. Reproduced by permission.

Effective Use of FCT

A number of factors enhance the use of FCT, an appropriate and effective antecedent intervention for decreasing behavior. We discuss the principal factors in the next sections. However, we recognize Andzik, Cannella-Malone, and Sigafoos's (2016) point that few studies have analyzed practitioners' fidelity in implementing FCT. Their review sheds light on this important issue.

Dense Schedule of Reinforcement

The alternative communicative response should produce the reinforcers that maintain the problem behavior on a continuous schedule of reinforcement during the early stages of communication training.

Decreased Use of Verbal Prompts

While teaching the alternative communicative response, verbal prompts such as saying "*look*" or "*watch me*" are used often. After the communicative response is established firmly, the trainer should gradually reduce any verbal prompts and, if possible, eliminate them altogether to remove any prompt dependence associated with the intervention (Miltenberger, Fuqua, & Woods, 1998).

Behavior Reduction Procedures

The effectiveness of FCT is likely to be enhanced if it is individualized within a treatment package consisting of extinction or time-out (Shirley et al., 1997).

Schedule Thinning

Thinning the reinforcement schedule for a firmly established communicative response is an important part of the FCT treatment package. Time-based procedures, such as constant time increase, proportional time increase, and session-to-session time increase, are not appropriate for schedule thinning with the alternative communicative response. They are incompatible with the methods used to differentially reinforce the alternative communicative behavior because the FCT intervention does not alter the MO that evokes the problem behavior. The alternative communicative behavior must remain sensitive to the evocative function of the MO to compete with the problem behavior. For example, consider a child with developmental disabilities who has a history of self-stimulatory behavior when presented with a difficult task. A therapist teaches the child to ask for assistance with these tasks (i.e., the alternative communicative behavior), which reduces the self-stimulatory behavior. After firmly establishing *asking for assistance*, the therapist or caregiver should not decrease instances of providing that assistance because such a decrease might break the alternative communicative behavior–reinforcer contingency, and risk the re-emergence of self-stimulation.

Hanley, Piazza, Fisher, Contrucci, and Maglieri (2001) recommended a procedure for schedule thinning that used a dense fixed-interval schedule of reinforcement (e.g., FI 2 sec, FI 3 sec) during the initial teaching of the alternative communicative response. Once the communicative response was established, they suggested gradually thinning the FI schedule. This procedure, in contrast to time-based procedures, maintained the contingency between responding and reinforcement. They cautioned that thinning the FI schedule during FCT interventions could produce undesirable high rates of the alternative communicative response that could disrupt home or classroom settings. Hanley and colleagues further suggested the use of picture cues and external "clocks" to announce when reinforcement is available, to control the undesirable high rate of the communicative response.

For further review of research on FCT schedule thinning and recommendations for practice, see Greer, Fisher, Saini, Owen, and Jones (2016) and Hagopian, Boelter, and Jarmolowicz (2011).

Table 26.6 summarizes the advantages and disadvantages of using FCT.

DEFAULT INTERVENTIONS

Smith (2011) defined default antecedent interventions as treatments "whose effects do not depend on specific identification of the variables that set the occasion for and maintain the problem behavior" (p. 297) and described three principal types: antecedent exercise, enriched environment, and restraint. Smith and Iwata (1997) noted that antecedent exercise is used regularly for self-injury, aggression, and stereotypy; enriched environment is most frequently applied for problem behaviors maintained by automatic positive reinforcement; and restraint is an appropriate intervention for severe behavior problems in limited selected situations.

Antecedent Exercise

Antecedent exercise requires the individual to engage in some effortful form of aerobic activity (e.g., walking, jogging, dancing, calisthenics, roller skating) prior to receiving a low-*p* task to complete. Upon completion of the exercise, the individual is directed to complete the task, and performance is recorded.

Research over a few decades has reported that antecedent exercise has decreased many maladaptive behaviors, such as SIB and aggression, as well as diverse behaviors such as inappropriate vocalizations, repetitive movements, and talking-out, out-of-seat, and stereotypic behaviors. "It is important to note that in contrast to other interventions involving effortful activity, such as overcorrection (Foxx & Azrin, 1972, 1973), antecedent exercise is implemented independently of occurrences of the problem behavior" (Smith, 2011, pp. 298–299).

Celiberti, Bobo, Kelly, Harris, and Handleman (1997) used a multielement design to analyze the effects of two levels of antecedent exercise on the self-stimulatory behavior of a 5-year-old boy with autism.

> The exercise conditions were applied immediately before periods of academic programming. Maladaptive self-stimulatory behaviors were separately tracked, enabling identification of behaviors that were more susceptible to change (e.g., physical self-stimulation and "out of seat" behavior) versus those that were more resistant (e.g., visual self-stimulation). Examination of temporal effects indicated a decrease in physical self-stimulation and "out of seat" behavior, but only for the jogging condition. In addition, sharp reductions in these behaviors were observed immediately following the jogging intervention and gradually increased but did not return to baseline levels over a 40 min period (p. 139). (See Figure 26.5.)

Enriched Environment

An **enriched environment** (EE) intervention provides noncontingent access to preferred sources of reinforcement (e.g., toys, games, social and recreation activities). This noncontingent access to preferred sources of reinforcement arranges a competition between the EE intervention and the stimulation provided by the problem behavior (Horner, 1980). When effective, this competition decreases the problem behavior.

Vollmer, Marcus, and LeBlanc (1994) examined interventions for three participants following inconclusive functional analyses. These participants included Ron and Korey, 3-year-old boys with severe disabilities and self-injurious behaviors (SIB), and Rhonda, a 4-year-old-girl, also with severe disabilities, as well as chronic hand mouthing. During a stimulus preference assessment (see Chapter 11), Vollmer et al. arranged an array of teacher- or parent-suggested items

TABLE 26.6 Possible Advantages and Disadvantages of Functional Communication Training

Advantages
• Excellent chance for generalization and maintenance of the alternative communicative response because the communicative response often functions to recruit reinforcement from significant others (Fisher, Kuhn, & Thompson, 1998).
• May have high social validity. Participants report preferences for FCT over other procedures to diminish behavior (Hanley et al., 1997).
Disadvantages
• FCT treatment packages usually include extinction, which may produce undesirable effects (see Chapter 22).
• The extinction procedure is difficult to use consistently, allowing for intermittent reinforcement of problem behaviors.
• Participants may emit inappropriately high rates of the alternative communicative response (Fisher et al., 1998).
• Recruitment of reinforcement can occur at inconvenient or impossible times for the caregiver (Fisher et al., 1998).
• FCT leaves intact the environment that evoked the problem behavior, which may limit its overall effectiveness (McGill, 1999).

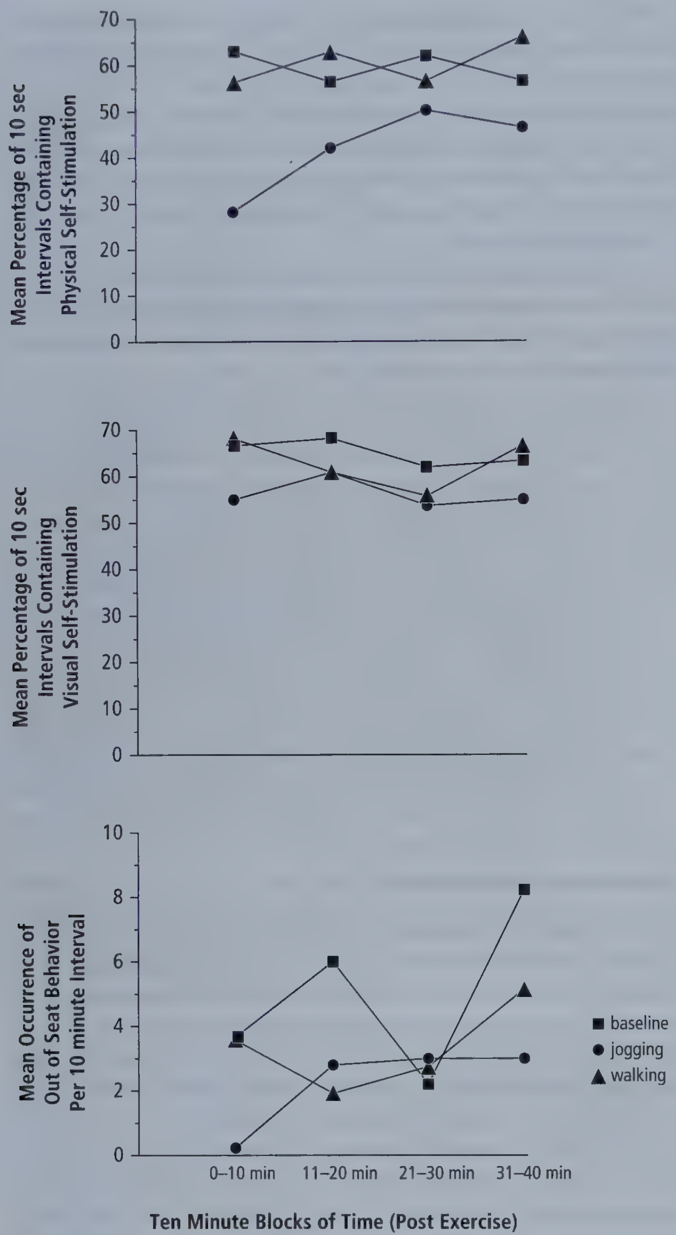

Figure 26.5 Mean percentage of intervals of physical self-stimulatory behaviors and visual self-stimulatory behaviors and mean frequency of "out of seat" behavior across four 10-min blocks of time after implementation of treatment conditions for baseline (open square), walking (open triangle), and jogging (filled circle).

From "The Differential and Temporal Effects of Antecedent Exercise on the Self-Stimulatory Behavior of a Child with Autism," by D. Celiberti, H. E. Bobo, K. S. Kelly, S. L. Harris, and J. S. Handleman, 1997, *Research in Developmental Disabilities, 18*, p. 147. Used by permission.

for each individual, including food, drinks, toys, and balls. Using standard assessment protocols, the researchers discovered the preferred and differential reinforcers for each child. For example, Rhonda preferred sound-making toys and cookies, while the other children preferred different items. The EE interventions of preferred stimuli decreased the aberrant behaviors of the three children.

Restraint

Restraint involves physically limiting, prohibiting, or securing an individual in such a manner that the target behavior cannot occur. Three forms of restraint as an antecedent intervention appear in the behavior analysis literature: personal restraint, protective equipment restraint, and self-restraint.

Personal Restraint

Personal restraint is "implemented in situations where problem behavior is highly likely to occur [and] involves caregivers physically securing and holding body parts, so that problem behavior cannot occur" (Smith, 2011, p. 300). Personal restraint as an antecedent intervention should not be confused with response blocking, which entails stopping a problem behavior that has been initiated (see Chapter 14).

Protective Equipment Restraint

Protective equipment restraints (e.g., padded helmets, arm splints, boxing gloves, padded hand mitts, safety belts, safety straps) are used to protect individuals from serious self-injury and to reduce the frequency of SIB (Smith, 2011). For example, Mazaleski, Iwata, Rogers, Vollmer, and Zarcone (1994) used oven mitts for treating the chronic hand mouthing of two women with profound intellectual disabilities. Marty was 33 years old, and Ava was 34 years old. Both lived in a public residential facility. Marty and Ava emitted chronic hand mouthing that produced mild tissue damage. In addition to hand mouthing, Ava also engaged in tongue pulling, which resulted in periodic irritation and ulcers. After collecting baseline on hand mouthing, two conditions were implemented. In a noncontingent-equipment condition, one participant wore oven mitts throughout an entire session. In a contingent-equipment condition, mitts were placed on the participant only following hand mouthing episodes. Results showed that both noncontingent and contingent mitts produced a large decrease in the rate of hand mouthing.

Self-restraint

Persons with self-injurious behavior often apply self-restraint. Wendy, a 12-year-old girl with Down syndrome, received treatment for hand-to-head hitting that caused vision loss and other facial injuries. Wendy applied self-restraint by "sitting on her hands or placing her arms between folded legs or wrapped in clothing. Wendy's caregivers reported that self-restraint was encouraged and seldom blocked, but that self-restraint interfered with adaptive skills" (Scheithauer, O'Connor, & Toby, 2015, p. 908).

The unique relationship between SIB and self-restraint raises important questions related to the controlling variables during treatment (Fisher & Iwata, 1996). Will the same reinforcement contingency maintain both behaviors? Do SIB and

self-restraint have a shared history, but different contingencies of reinforcement? Will access to SIB (or self-restraint) function as reinforcement for self-restraint (or SIB)? Research has begun to address these questions. For example, Smith, Lerman, and Iwata (1996) suggested that self-restraint provided positive reinforcement for SIB. Fisher, Grace, and Murphy (1996) proposed that self-restraint was maintained by negative reinforcement by escape from blocking SIB (e.g., pain). Derby, Fisher, and Piazza (1996) found that self-restraint and SIB were members of the same functional response class (both behaviors were maintained by social attention) and suggested noncontingent reinforcement as a possible treatment for self-restraint and SIB. Much research will be required to fully understand the variables that account for the effects of self-restraint.

SUMMARY

Defining and Classifying Antecedent Interventions

1. An antecedent intervention is implemented *prior to* and *independent of* the target behavior's occurrence.

2. Smith (2011) identified two broad categories of antecedent interventions: *Function-based antecedent interventions* manipulate at least one component of the contingency identified as maintaining the problem behavior; *default interventions* do not depend on identifying the variables that evoke and maintain the problem behavior.

3. Antecedent interventions can also be classified by whether or not differential consequences are required for behavior change. *Contingency-independent* antecedent interventions do not depend on differential consequences for the target behavior; *contingency-dependent* antecedent interventions depend on differential consequences for the target behavior (or alternative behavior) in the presence or absence of the antecedent.

Noncontingent Reinforcement

4. NCR is an antecedent intervention in which stimuli with known reinforcing properties are delivered on a fixed-time (FT) or variable-time (VT) schedule independent of the learner's behavior.

5. An NCR-enriched environment may function as an abolishing operation (AO) that reduces motivation to engage in the problem behavior.

6. A functional analysis of the reinforcing contingency maintaining the problem behavior determines whether NCR is implemented with positive reinforcement, negative reinforcement (escape), or automatic reinforcement.

High-probability Instructional Sequence

7. The basic procedure for implementing the high-probability instructional sequence (high-*p*) is as follows:
   - First, present two to five instructions for which the participant has a history of compliance and reinforce each compliant response.
   - Second, immediately after the participant has complied with several high-*p* instructions in sequence, present a target (i.e., low-*p*) instruction.
   - Third, gradually fade the ratio of high-*p* to low-*p* instructions to 1-to-1.

8. The reductive effects of the high-*p* instructional sequence on noncompliance resemble the abative effects of an AO that reduces the current potency of reinforcement for noncompliance with the low-probability requests (i.e., reducing the value of escape from requests).

9. Behavioral momentum is sometimes used to describe the effects produced by the high-*p* instructional sequence.

Functional Communication Training

10. FCT establishes an appropriate communicative behavior to compete with problem behaviors evoked by a motivating operation (MO).

11. The practitioner uses DRA to teach an adaptive response that produces the same reinforcer that has maintained the problem behavior, thereby making the alternative communicative response functionally equivalent to the problem behavior.

Default Interventions

12. Default antecedent interventions do not depend on identifying the variables that evoke and maintain the problem behavior.

13. Antecedent exercise requires the participant to engage in some form of aerobic activity prior to receiving an instruction or entering an environment in which the problem behavior has frequently occurred.

14. The noncontingent access to preferred sources of reinforcement provided by an enriched environment intervention arranges a competition between the intervention and the stimulation provided by the problem behavior.

15. Three methods of restraint—physically limiting, prohibiting, or securing an individual in such a manner that the problem behavior cannot occur—have been evaluated in the applied behavior analysis literature: personal restraint, protective equipment restraint, and self-restraint.

KEY TERMS

antecedent intervention
behavioral momentum
fixed-time schedule (FT)
functional communication training (FCT)
high-probability (high-p) request sequence
noncontingent reinforcement (NCR)
variable-time schedule (VT)

MULTIPLE-CHOICE QUESTIONS

1. Functional communication training is considered to be:
   a. Consequent intervention
   b. Punishment strategy
   c. Antecedent intervention
   d. Behavioral momentum technique

   Hint: (See "Functional Communication Training")

2. Behaviors selected for a high-p request sequence should:
   a. Be a part of the learner's current repertoire
   b. Be new behavior(s) the learner has to acquire
   c. Have a very long duration of occurrence
   d. Be those behaviors with which the learner is not compliant

   Hint: (See "High-Probability Instructional Sequence")

3. To effectively implement a high-p request sequence, it is important to:
   a. Select behaviors not in the learner's current behavior repertoire
   b. Not acknowledge compliance
   c. Use reinforcers with limited reinforcing value
   d. Present requests in a rapid sequence

   Hint: (See "High-Probability Instructional Sequence")

4. Noncontingent reinforcement involves the presentation of:
   a. Stimuli with unknown reinforcing properties that are delivered on a fixed-time or variable time schedule independent of the learner's behavior
   b. Stimuli with known reinforcing properties that are delivered on a fixed-time or variable-time schedule independent of the learner's behavior
   c. Stimuli with known reinforcing properties that are delivered on a fixed-ratio or variable-ratio schedule independent of the learner's behavior
   d. Stimuli with known reinforcing properties that are delivered on a fixed-time or variable-time schedule dependent on the learner's behavior

   Hint: (See "Noncontingent Reinforcement")

5. Noncontingent reinforcement may effectively decrease problem behavior because:
   a. Reinforcers that maintain the problem behavior are available freely and frequently.
   b. Reinforcers that maintain the problem behavior are withheld and made contingent upon the occurrence of alternative behaviors.
   c. Reinforcers that maintain the problem behavior are presented only when the problem behavior occurs.
   d. Reinforcers do not maintain the problem behavior presented regardless of the behaviors.

   Hint: (See "Noncontingent Reinforcement")

6. Functional communication training:
   a. Develops alternative behaviors that are sensitive to abolishing operations
   b. Develops alternative behaviors that create changes in motivating operations
   c. Develops alternative behaviors that are sensitive to establishing operations
   d. Develops alternative behaviors that produce punishing effects

   Hint: (See "Functional Communication Training")

7. Antecedent interventions are also known as:
   a. Antecedent procedures
   b. Antecedent control
   c. Antecedent manipulations
   d. All of these

   Hint: (See "Defining and Classifying Antecedent Interventions")

ESSAY-TYPE QUESTIONS

1. What is an antecedent intervention?
   Hint: (See "Defining and Classifying Antecedent Interventions")
2. Describe noncontingent reinforcement (NCR) and its application as an antecedent intervention strategy.
   Hint: (See "Noncontingent Reinforcement")
3. Describe high-probability (high-p) request sequence and its application as an antecedent intervention strategy.
   Hint: (See "High-Probability Instructional Sequence")
4. Describe functional communication training (FCT) and its application as an antecedent intervention strategy.
   Hint: (See "Functional Communication Training")

NOTES

1. Interpreting the NCR procedure as presenting a reinforcer is technically inconsistent with the definition of reinforcement, which requires a response-reinforcer relation (Poling & Normand, 1999). We use NCR to describe the time-based delivery of stimuli with known reinforcing properties because applied behavior analysts have continued its use, and the term NCR serves a descriptive purpose.
2. Chapter 27 provides a detailed description of functional behavior assessment.
3. To learn more about behavioral momentum theory describing response rate and resistance to change as two separate aspects of operant behavior, see Craig, Nevin, and Odum (2014); Greer, Fisher, Romani, and Saini (2016); Nevin (1992); and Shahan and Sweeney (2011).

PART 10

Functional Assessment

Changing behavior is often challenging, perplexing, and frustrating. The behavior analyst's task of determining what to do and how to do it can be particularly difficult when helping people with chronic problem behaviors that have been resistant to change. In Chapter 27 Stephanie Peterson and Nancy Neef describe an assessment process that explores the function (or purpose) a behavior serves for a person. Functional behavior assessment enables behavior analysts to make empirically based hypotheses for *why* problem behaviors occur, information that can point to the design of effective interventions. Peterson and Neef describe the basis for functional behavior assessments and their role in treating and preventing problem behaviors, and present case examples illustrating three methods for conducting functional behavior assessments.

CHAPTER 27

Functional Behavior Assessment

Stephanie M. Peterson and Nancy A. Neef

LEARNING OBJECTIVES

- Name the functions that problem behavior can serve.
- Describe the role functional behavior assessment plays in preventing problem behavior and developing interventions for problem behavior.
- State the different methods of conducting a functional behavior assessment.
- State the primary characteristics of and rationale for conducting a descriptive assessment.
- Describe various methods for gathering descriptive assessment data and under what circumstances each is appropriate.
- Given a set of descriptive data, interpret the data to form a hypothesis regarding the possible function of problem behavior.
- State the primary characteristics of and rationale for conducting a functional analysis as a form of functional behavior assessment.
- Describe how to conduct a functional analysis.
- Given a set of data from a functional analysis, interpret the data to determine the function of problem behavior.

When it is time to wash hands before lunch, Stella turns the handles of the faucet and places her hands under the running water, but Flo screams and tantrums. The teacher is confused about why Stella performs so well in this context and Flo performs so poorly. Consequently, she is at a loss as to how to respond when Flo screams and tantrums. The crying and tantrums could occur for a variety of reasons. To understand why they are occurring, the teacher could perform a functional behavior assessment of Flo's problem behaviors. This assessment may provide information valuable for creating an effective behavior intervention. Consistent with the scientific precept of determinism described in Chapter 1, behaviors—including problem behaviors—are lawfully related to other events in the environment. **Functional behavior assessment (FBA)** enables hypotheses about the relations among specific types of environmental events and behaviors. Specifically, FBA is designed to obtain information about the purposes (functions) a behavior serves for a person. This chapter describes the basis for FBA, its role in the intervention and prevention of behavior difficulties, and alternative approaches to functional assessment. We will revisit Flo's problem behavior throughout this chapter to illustrate.

FUNCTIONS OF BEHAVIOR

Evidence from decades of research indicates that both desirable and undesirable behaviors, whether washing hands or screaming and tantrumming, are learned and maintained through interaction with the social and physical environment (see Schlinger & Normand, 2013, for a review). As explained in Chapters 11 and 12, these behavior–environment interactions are described as positive or negative reinforcement contingencies. Behaviors can be strengthened by either "getting something" or "getting out of something."

FBA is used to identify the type and source of reinforcement for challenging behaviors as the basis for intervention efforts designed to decrease the occurrence of those behaviors. FBA can be thought of as a reinforcer assessment of sorts. It identifies the reinforcers currently maintaining problem behavior. Those reinforcers might be positive or negative social reinforcers provided by someone who interacts with the person, or automatic reinforcers produced directly by the behavior itself. The idea behind FBA is that if these reinforcement contingencies can be identified, then interventions can be designed to decrease problem behavior and increase adaptive behavior by altering these contingencies. FBA fosters proactive, positive interventions for problem behavior. Although reinforcement contingencies are discussed in other chapters, a brief review of their role in FBA is warranted.

Positive Reinforcement

Social Positive Reinforcement (Attention)

Problem behavior often results in immediate attention from others, such as head turns; surprised facial expressions; reprimands; attempts to soothe, counsel, or distract; and so on. These reactions can positively reinforce problem behavior (even if

inadvertently), and the problem behavior is then more likely to occur in similar circumstances. Problem behavior maintained by positive reinforcement in the form of reactions from others can often occur in situations in which attention is otherwise infrequent, whether because the person does not have a repertoire to gain attention in desirable ways or because others in the environment are typically otherwise occupied.

Tangible Reinforcement

Many behaviors result in access to reinforcing materials or other stimuli. Just as pressing a button on the television remote changes the channel to a desired television show, problem behaviors can produce reinforcing outcomes. A child may cry and tantrum until a favorite television show is turned on; stealing another child's candy produces access to the item taken. Problem behaviors may develop when they consistently produce a desired item or event. This often occurs because providing the item temporarily stops the problem behavior (e.g., tantrum), although it can have the inadvertent effect of making the problem behavior more probable in the future under similar circumstances.

Automatic Positive Reinforcement

Some behaviors do not depend on the action of others to provide an outcome; some behaviors directly produce their own reinforcement. For example, thumb sucking might be reinforced by physical stimulation of either the hand or the mouth. Hand flapping while looking at a light might be reinforced by the visual stimulation of the light being blocked and revealed, as the hand flapping might simulate a flashing light. Swinging a tennis racket correctly as a tennis ball approaches and hits the head of the racket might be reinforced by the "pop" sound the ball makes when it hits the "sweet spot" of the racket. Placing hands under the faucet might be reinforced by the warm sensation of water on the skin. A behavior is assumed to be maintained by automatic reinforcement only after social reinforcers have been ruled out (e.g., when the behavior occurs even when the individual is alone).

Negative Reinforcement

Social Negative Reinforcement (Escape)

Many behaviors are learned as a result of their effectiveness in terminating or postponing aversive events. Hanging up the phone terminates interactions with a telemarketer; completing a task or chore terminates requests from others to complete it or the demands associated with the task itself. Problem behaviors can be maintained in the same way. Behaviors such as aggression, self-injurious behavior (SIB), and bizarre speech may terminate or avoid unwanted interactions with others. For example, noncompliance postpones engagement in a nonpreferred activity, and disruptive classroom behavior often results in the student being sent out of the classroom, thereby allowing escape from instructional tasks or teacher demands. All of these behaviors can be strengthened by negative reinforcement to the extent that they enable the individual to escape or avoid difficult or unpleasant tasks, activities, or interactions.

Automatic Negative Reinforcement

Aversive stimulation, such as a physically painful or uncomfortable condition, is a motivating operation that makes its termination reinforcing. Behaviors that directly terminate aversive stimulation are therefore maintained by negative reinforcement that is an automatic outcome of the response. Automatic negative reinforcement can account for behaviors that are either appropriate or harmful. For example, putting calamine lotion on a poison ivy rash can be negatively reinforced by alleviation of itching, but intense or prolonged scratching that breaks the skin can be negatively reinforced in the same manner. Some forms of SIB may distract from other sources of pain, which may account for their correlation with specific medical conditions (e.g., DeLissovoy, 1963).

Function Versus Topography

Several points can be made from the previous discussion of the sources of reinforcement for behavior. It is important to recognize that environmental influences do not make distinctions between desirable and undesirable topographies of behavior; the same reinforcement contingencies that account for desirable behavior can also account for undesirable behavior. For example, Stella, the child who washes and dries her hands before lunch, has probably received praise for doing so. Flo, the child who frequently engages in tantrums in the same situation, may have received attention (in the form of reprimands). Both forms of attention have the potential to reinforce the respective behaviors.

Likewise, the same topography of behavior can serve different functions for different individuals. For example, tantrums may be maintained by positive reinforcement in the form of attention for one child and by negative reinforcement in the form of escape for another child (e.g., Kennedy, Meyer, Knowles, & Shukla, 2000).

Because different behaviors that look quite different can serve the same function, and behavior of the same form can serve different functions under different conditions, the *topography*, or form, of a behavior often reveals little useful information about the conditions that account for it. Identifying the *conditions* that account for a behavior (its function), in contrast, suggests what conditions need to be altered to change the behavior. Assessing the function of a behavior can therefore yield useful information with respect to intervention strategies that are likely to be effective.

ROLE OF FUNCTIONAL BEHAVIOR ASSESSMENT IN INTERVENTION AND PREVENTION

FBA and Intervention

If a causal relation between environmental events and a problem behavior can be determined, and that relation can be altered, the problem behavior will occur less often. Interventions informed by FBA primarily consist of three strategic approaches: alter antecedent variables, alter consequent variables, and teach alternative behaviors.

Alter Antecedent Variables

FBA can identify antecedents that might be altered so the problem behavior is less likely to occur. Altering the antecedents

for problem behavior can change and/or eliminate either (a) the motivating operation for problem behavior or (b) the discriminative stimuli that trigger problem behavior. For example, the motivating operation for tantrums when Flo is asked to wash her hands before lunch could be modified by changing the characteristics associated with lunch so that the avoidance of particular events is no longer reinforcing. Depending on the function of the tantrums, this might involve initially reducing table-setting demands, altering seating arrangements to minimize taunts from a sibling or peer, or reducing snacks before lunch and offering more preferred foods during lunch. Alternatively, if the FBA shows that running water is the discriminative stimulus that triggers problem behavior when Flo is asked to wash her hands, she might be given a waterless antibacterial hand gel instead. In this case, the discriminative stimulus for problem behavior has been removed, thereby decreasing problem behavior.

Alter Consequent Variables

FBA can also identify a source of reinforcement to be eliminated for the problem behavior. For example, an FBA that indicates Flo's tantrums are maintained by social negative reinforcement (avoidance or escape) suggests a variety of treatment options, which, by altering that relation, are likely to be effective. Flo's tantrums can be placed on extinction by ensuring that the reinforcer (e.g., avoidance of the activities associated with setting the table for snack or lunch) no longer follows problem behavior (tantrums). Another approach could be to provide the reinforcer for alternative behaviors instead of for the problem behavior. Finally, the schedule might be modified so that hand washing follows—and thereby provides escape from—an event that is even less preferred.

Teach Alternative Behaviors

FBA can also identify the source of reinforcement to be provided for appropriate replacement behaviors. Alternative appropriate behaviors that have the same function (i.e., produce the same reinforcer) as tantrums could be taught. For example, if Flo's tantrums are maintained by escaping lunchtime activities, she might be taught to touch a card communicating "later" after washing her hands, to produce a delay in being seated at the lunch table.

FBA and Default Technologies

Interventions based on an FBA may be more effective than those selected without consideration of behavioral function (e.g., Ervin et al., 2001; Iwata et al., 1994b). Understanding *why* a behavior occurs often suggests *how* it can be changed for the better. In contrast, premature efforts to treat problem behavior before seeking an understanding of the purposes it has for a person can be inefficient, ineffective, and, in some cases, harmful. For example, suppose that a time-out procedure is implemented in an attempt to attenuate Flo's tantrums when she is asked to wash her hands before lunch. Flo is removed from the hand-washing activity to a chair in the corner of the room. It may be, however, that the events typically following hand washing (those associated with lunch time, such as the demands of arranging chairs or setting the table or interactions with others) are aversive for Flo, and tantrumming has allowed her to avoid those events. In this case, the intervention would be ineffective because it has done nothing to alter the relation between tantrums and the consequence of avoiding the aversive events associated with lunch. In fact, the intervention may exacerbate the problem if it produces a desired outcome for Flo. If stopping the hand-washing activity and having Flo sit on a chair as "time-out" for tantrumming enables her to avoid the aversive lunchtime events—or to escape them altogether—tantrums may be more likely under similar circumstances in the future. When the time-out intervention proves unsuccessful, other interventions might be attempted. Without understanding the function that the problem behavior serves, however, the effectiveness of those interventions cannot be predicted.

At best, a trial-and-error process of selecting and implementing interventions without consideration of behavioral function can be lengthy and inefficient. At worst, such an approach may cause the problem behavior to become more frequent or severe. As a result, caregivers might resort to increasingly intrusive, coercive, or punishment-based interventions, which are often referred to as *default technologies*.

FBA can decrease reliance on default technologies and contribute to more effective interventions in several ways. When FBAs are conducted, reinforcement-based interventions are more likely to be implemented than are those that include punishment (Pelios, Morren, Tesch, & Axelrod, 1999). In addition, the effects of interventions based on FBAs are likely to be more durable than those that do not take the function of problem behavior into account. If contrived contingencies are superimposed on unknown contingencies that are maintaining the behavior, their continuation is often necessary to maintain improvements in the behavior. If those superimposed contingencies are discontinued, the behavior will continue to be influenced by the unchanged operative contingencies.

FBA and Prevention

By furthering understanding of the conditions under which certain behaviors occur, FBA can also contribute to the prevention of difficulties. Although problem behavior may be suppressed without regard to its function by using punishment procedures, additional behaviors not subject to the punishment contingencies may emerge because the motivating operations for problem behavior remain. For example, contingent loss of privileges might eliminate tantrums that occur whenever Flo is asked to wash her hands, but it will not eliminate avoidance as a reinforcer or the conditions that establish avoidance as a reinforcer. Thus, other behaviors that result in avoidance, such as aggression, property destruction, or running away may develop. These unintended effects are less likely to occur with interventions that address (rather than override or compete with) the reinforcing functions of problem behavior.

On a broader scale, the accumulation of FBA data may further assist in prevention efforts by identifying the conditions that pose risks for the future development of problem behaviors. Preventive efforts can then focus on those conditions. For example, based on data from 152 analyses of the reinforcing functions of self-injurious behavior (SIB), Iwata and colleagues (1994b) found that escape from task demands or other aversive stimuli accounted for the behavior in the largest proportion of cases. The authors speculated that this outcome might have

been an unintended result of a move toward providing more aggressive treatment. For example, if Flo tantrums when she is required to wash her hands, the teacher might assume that she does not know how to wash her hands. The teacher might decide to replace playtime with a period of intensive instruction on hygiene. Rather than decreasing problem behavior, such interventions may exacerbate it. The data reported by Iwata and colleagues suggest that preventive efforts should be directed toward modifying instructional environments (such as providing more frequent reinforcement for desirable behavior, opportunities for breaks, or means to request and obtain help with difficult tasks) so that they are less likely to function as sources of aversive stimulation (motivating operations) for escape.

OVERVIEW OF FBA METHODS

FBA methods can be classified into three types: (a) functional (experimental) analysis, (b) descriptive assessment, and (c) indirect assessment. The methods can be arranged on a continuum with respect to considerations such as ease of use and the type and precision of information they yield (see Figure 27.1). Selecting the method or combination of methods that will best suit a particular situation requires consideration of each method's advantages and limitations. We discuss functional analysis and its variations first because descriptive and indirect methods of functional assessment developed as an outgrowth of functional analysis. As noted later, functional analysis is the only FBA method that allows practitioners to confirm hypotheses regarding functional relations between problem behavior and environmental events.

Functional (Experimental) Analysis

Basic Procedure

Functional analysis procedures were first pioneered by Iwata, Dorsey, Slifer, Bauman, and Richman (1994a). In a **functional analysis**, antecedents and consequences representing those in the person's natural environment are arranged so that their separate effects on problem behavior can be observed and measured. This type of assessment is often referred to as an *analog* because antecedents and consequences similar to those occurring in the natural routines are presented in a systematic manner, but the analysis is not conducted in the context of naturally occurring routines. Analog conditions are often used because they allow the behavior analyst to better control the environmental variables that may be related to the problem behavior than can be accomplished in naturally occurring situations. Analogs refer to the arrangement of variables rather than the setting in which assessment occurs. Research has found that functional analyses conducted in natural environments (e.g., classroom settings) often yield the same (and, in some cases, clearer) results compared to those conducted in simulated settings (Noell, VanDerHeyden, Gatti, & Whitmarsh, 2001).

Functional analyses (FA) typically comprise four conditions: three test conditions—contingent attention, contingent escape, and alone—and a control condition, in which problem behavior is expected to be low because reinforcement is freely available and no demands are placed on the individual (see Table 27.1). However, it should be understood that there is no "standard" FA. FAs should be flexible and individualized. The practitioner can implement myriad conditions to address

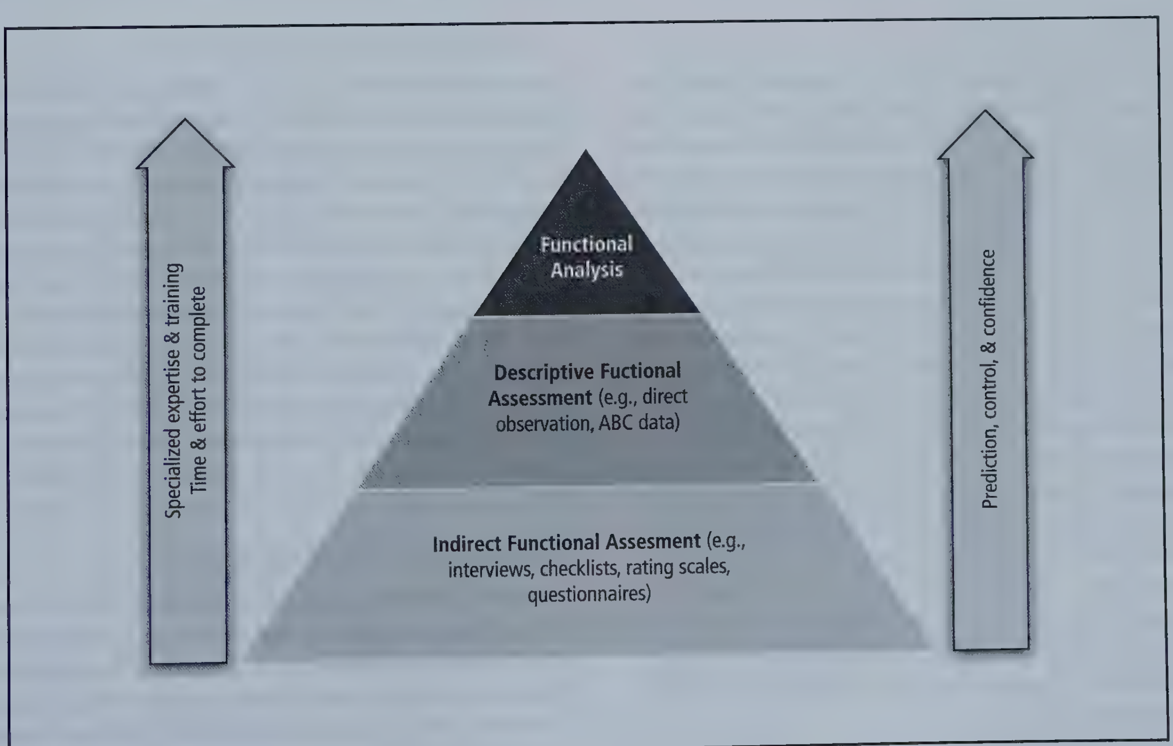

Figure 27.1 FBA methods. The amount or value of each dimension or outcome identified within the arrows increases from the bottom to the top of the pyramid.

Diagram contributed by Rebecca Eldridge.

TABLE 27.1 Motivating Operations and Reinforcement Contingencies for Typical Control and Test Conditions of a Functional Analysis

Condition	Antecedent conditions (motivating operation)	Consequences for problem behavior
Play (control)	Preferred activities are continuously available, social attention is provided, and no demands are placed on the person.	Problem behavior is ignored or neutrally redirected.
Contingent attention	Attention is diverted or withheld from the person.	Attention is provided in the form of mild reprimands or soothing statements (e.g., "Don't do that. You'll hurt someone.").
Contingent escape	Task demands are delivered continuously using a three-step prompting procedure (e.g., [1] "You need to fold the towel." [2] Model folding the towel. [3] Provide hand-over-hand assistance to fold the towel).	Break from the task is provided by removing task materials and stopping prompts to complete the task.
Contingent tangible	After having access to a preferred activity/toy, the preferred activity/toy is removed (e.g., "My turn to play with that."). Moderately preferred or neutral toys are still continuously available, as is adult attention.	The preferred activity/toy is returned to the individual.
Alone	Low level of environmental stimulation is present (i.e., therapist, task materials, and play materials are absent).	Problem behavior is ignored or neutrally redirected.

specific hypotheses. For example, some FAs also include a tangible test condition (Day, Rea, Schussler, Larsen, & Johnson, 1988). Each test condition contains a motivating operation (MO) and a potential source of reinforcement for problem behavior. The conditions are presented systematically one at a time and in an alternating sequence, and occurrences of problem behavior are recorded during each session. Sessions are repeated to determine the extent to which problem behavior consistently occurs more often under one or more conditions relative to another.

Interpreting Functional Analyses

The function problem behavior serves for a person can be determined by visually inspecting a graph of the results of an analysis to identify the condition(s) under which high rates of the behavior occurred. A graph for each potential behavioral function is shown in Figure 27.2. Problem behavior is expected to be low in the play condition because no motivating operations for problem behavior are present. Elevated problem behavior in the contingent attention condition suggests that problem behavior is maintained by social positive reinforcement (see graph in top left of Figure 27.2). Elevated problem behavior in the contingent escape condition suggests that problem behavior is maintained by negative reinforcement (graph in top right of Figure 27.2). Elevated problem behavior in the alone condition suggests that problem behavior is maintained by automatic reinforcement (graph in bottom left of Figure 27.2). Further analysis is needed to determine if the source of the automatic reinforcement is positive or negative. Problem behavior may be maintained by multiple sources of reinforcement. For example, if problem behavior is elevated in the contingent attention and contingent escape conditions, it is most likely maintained by both positive and negative reinforcement.

If problem behavior occurs frequently in all conditions (including the play condition), or is variable across conditions, responding is considered *undifferentiated* (see graph in bottom right of Figure 27.2). Such results are inconclusive, but can also occur with behavior that is maintained by automatic reinforcement.

Functional analysis has been replicated and extended in hundreds of studies, thereby demonstrating its generality as an approach to the assessment and treatment of a wide range of behavior difficulties. (See the 1994 and 2013 special issues of the *Journal of Applied Behavior Analysis* for a sample of such applications and Hanley, Iwata, & McCord, 2003, and Beavers, Iwata, & Lerman, 2013, for reviews.)

Advantages of Functional Analysis

The primary advantage of functional analysis is its ability to yield a clear demonstration of the variable or variables that influence the occurrence of a problem behavior. In fact, functional (experimental) analyses are the standard of scientific evidence by which other assessment alternatives are evaluated, and represent the method most often used in research on the assessment and treatment of problem behavior (Arndorfer & Miltenberger, 1993). Because functional analyses allow valid conclusions concerning the variables that maintain problem behavior, they have enabled the development of effective reinforcement-based treatments and less reliance on punishment procedures (Brosnan & Healy, 2011; Ervin et al., 2001; Horner, Carr, Strain, Todd, & Reed, 2002; Iwata et al., 1994b; Pelios et al., 1999).

Limitations of Functional Analysis

A risk of functional analysis, however, is that the assessment process may temporarily strengthen or increase the undesirable behavior to unacceptable levels, or possibly result in the behavior acquiring new functions. Second, relatively little is known about the acceptability of functional analysis procedures to practitioners (Ervin et al., 2001; Reid & Nelson, 2002). The deliberate arrangement of conditions that set the occasion for, or potentially reinforce, problem behavior can

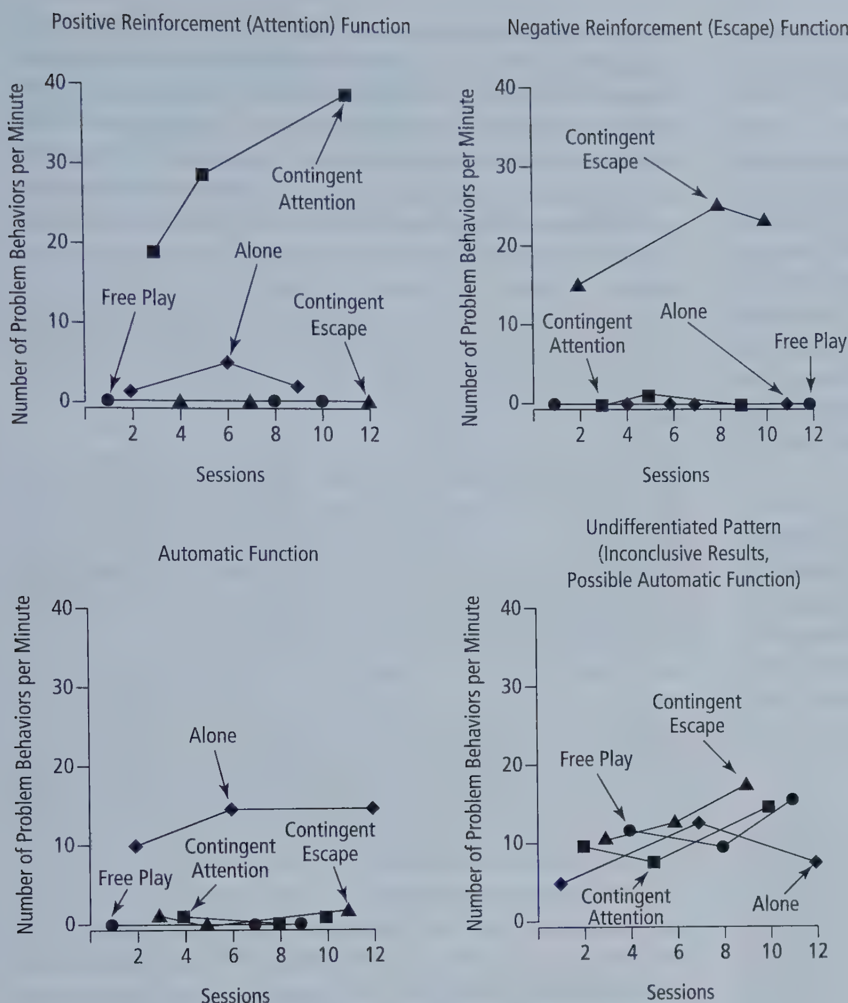

Figure 27.2 Data patterns typical of each behavioral function during a functional analysis.

be counterintuitive to persons who do not understand its purpose (or that such conditions are analogs for what occurs in the natural routine). O'Neill, Bundock, Kladis, and Hawken (2015) found that teachers reported positive perceptions of, and willingness to engage in, systematic direct observations and functional analysis manipulations. Interestingly, their positive perceptions were reportedly higher than those of school psychologists. School psychologists also expressed more concern about the time and effort required to conduct FBAs. Across both teachers and school psychologists, the most concerns were expressed about FA procedures. O'Neill and colleagues suggest that some of the concerns about these issues emanated from a lack of training and a lack of time to conduct the analyses. A third limitation is that some behaviors (e.g., those that, albeit serious, occur infrequently) may not be amenable to functional analyses due to setting and other factors. For example, if proper safety equipment or individuals with enough training to keep the client safe are not available, the setting may not be safe for conducting the FA. Fourth, functional analyses that are conducted in contrived settings might not detect the variables that account for the occurrence of the problem behavior in the natural environment, particularly if the behavior is controlled by idiosyncratic variables that are not represented in the functional analysis conditions (e.g., Noell et al., 2001). Finally, the time, effort, and professional expertise required to conduct and interpret functional analyses have been frequently cited as obstacles to its widespread use in practice (e.g., Spreat & Connelly, 1996; 2001, Volume 2 issue of *School Psychology Review*), although Hanley (2012) argues that these perceptions are not warranted.

Of course, untreated or ineffectively treated problem behaviors also consume a great deal of time and effort (without a constructive long-term outcome), and implementation of effective treatments (based on an understanding of the variables that maintain them) is likely to require skills similar to those involved in conducting functional analyses. These concerns have led to research on ways to enhance the practical use of functional analyses, including variations and the development of alternative methods of FBA described in the following sections.

Variations of Functional Analysis Procedures

Rather than dictating particular settings or conditions, functional analysis procedures achieve relevance through flexible arrangements tailored to individual circumstances. Some procedural variations are described here; for a review, see Lydon, Healy, O'Reilly, and Lang (2012).

Brief Functional Analysis. Functional analyses are typically conducted across multiple sessions. Sometimes time constraints or the severity of the problem behavior may restrict the number of sessions that can be conducted. In such circumstances, a **brief functional analysis** (Derby et al., 1992; Northup et al., 1991) may be appropriate. In a brief functional analysis, only one or two 5- to 10-min sessions are conducted for each condition. A convincing demonstration of function can be achieved by either alternating a condition that produces problem behavior with one that does not or conducting a contingency reversal. A contingency reversal is when the practitioner first makes the putative reinforcer contingent on one target behavior, such as tantrums, and then on an appropriate replacement behavior, such as making requests. (See the case example with Marie later in this chapter for an illustration.)

A brief functional analysis can be a robust procedure (Tincani, Castrogiavanni, & Axelrod, 1999) that preserves many advantages of an FA; however, it reveals a function clearly in fewer cases than a full functional analysis (Kahng & Iwata, 1999; Wallace & Knights, 2003). Some researchers (e.g., Vollmer, Marcus, Ringdahl, & Roane, 1995) have suggested that practitioners may want to consider beginning with a brief functional analysis and proceeding to a full functional analysis only if clear and replicable patterns do not emerge.

Conducting Functional Analyses in Natural Settings. Although not a requirement of functional analyses, they are often conducted in clinical settings. However, it can be advantageous to conduct functional analyses in the setting where the problem behaviors typically occur because the relevant stimulus cues are present in those settings. Sasso and colleagues (1992) provided one of the first demonstrations of functional analysis in classroom settings. Since then, many others have demonstrated the utility of functional analysis in the classroom (e.g., Wright-Gallo, Higbee, Reagon, & Davey, 2006), vocational (e.g., Wallace & Knights, 2003), and home settings (e.g., Wacker et al., 2013). One challenge when implementing functional analyses in natural settings is that the procedures can be disruptive to ongoing routines and may require additional supervision so that the other students, children, or clients are appropriately supervised while the teacher or caregiver devotes his or her attention to the analysis. An adaptation that can be made in natural settings is to use a trial-based approach, which may be more easily embedded into the ongoing activities of the classroom (Sigafoos & Saggers, 1995).

Trial-based Functional Analysis. A **trial-based functional analysis** (Bloom, Iwata, Fritz, Roscoe, & Carreau, 2011; Lambert, Bloom, & Irvin, 2012; Sigafoos & Sagers, 1995) consists of a series of trials interspersed among classroom activities. (See the case example with Carson later in this chapter for an illustration.) Each trial consists of two components, each lasting 1 minute. The first component consists of presenting the establishing operation and contingency for problem behavior (test condition), and the second component consists of continuous access to the reinforcer (control condition). For example, during the first component, a demand may be placed on the child and as soon as a tantrum occurs, the demand is terminated. During the second component, a task break is continuously provided. These conditions are implemented at times when they naturally occur (e.g., during free play periods for tangible conditions and during classroom instruction for escape conditions). Teachers may be able to perform the procedure with fidelity in their classrooms (Rispoli et al., 2015) and find it more manageable than session-based functional analyses. However, Bloom et al. describe a number of considerations that may result in discrepant results using trial-based functional analyses. For example, exposure to the relevant establishing operations and consequences may be too brief to evoke or maintain problem behavior.

Synthesized Functional Analyses. Hanley, Jin, Vanselow, and Hanratty (2014) and Jessel, Hanley, and Ghaemmaghami (2016) describe a variation of functional analysis that is designed to increase efficiency by using an **interview-informed synthesized contingency analysis** (IISCA). In the test condition, multiple contingencies are implemented simultaneously (e.g., attention and escape) when the problem behavior is demonstrated. In the control condition, those same reinforcers are presented noncontingently and continuously. For example, for one participant, Gail, in Hanley et al. (2014), problem behavior was not observed in the typical attention and tangible conditions, even though the behavior analysts hypothesized these were the variables maintaining her problem behavior. When these two contingencies were presented together (i.e., both attention *and* tangibles presented simultaneously contingent on problem behavior), a clear pattern of problem behavior emerged, as compared to a condition in which attention and tangibles were available continuously. Furthermore, these effects were observed only when Gail's mother presented the contingencies and not when the behavior analyst presented them.

This technology may have particular utility when problem behavior is not observed in typical FA conditions and when the behavior analyst suspects multiple contingencies may be maintaining problem behavior. At this time, the limited research that has compared IISCA with functional analysis is conflicting (Fisher, Greer, Romani, Zangrillo, & Owen, 2016; Hanley et al., 2014). Thus, the utility of IISCA is as yet unclear. We suggest that behavior analysts closely monitor additional research on this topic as it emerges.

Latency-based Functional Analysis. Sometimes, problem behavior is so severe that it is not possible to conduct an assessment that requires repeated occurrences of the problem behavior. In these cases, a **latency-based functional analysis** may be helpful (Thomasen-Sassi, Iwata, Neidert, & Roscoe, 2011). (See the case example with Elija later in this chapter for an illustration.) In a latency-based functional analysis, like a trial-based assessment, each session is terminated as soon as a problem behavior occurs. However, in this case, the session may last longer than 1 minute, because the establishing operation is present as long as necessary to evoke the problem behavior (or until a pre-established time limit has expired). The index of problem behavior is the latency from onset of the

establishing operation to the first occurrence of the problem behavior. Using a latency-based measure can reduce the number of occurrences of problem behavior necessary for analysis and shorten the time required to conduct the analysis. As with trial-based assessments, a limitation to latency-based assessment is that there is only one exposure to the contingency per session. Analyses that rely on response-repetition measures are generally preferable.

Functional Analysis of Precursors. Sometimes, even one occurrence of problem behavior can be so severe that evoking it poses unacceptable risk to the client and/or others. In these cases, it can be helpful to conduct the functional analysis on precursor behavior—a behavior that reliably precedes the target behavior (Borrero & Borrero, 2008; Herscovitch, Roscoe, Libby, Bourret, & Ahearn, 2009; Najdowski, Wallace, Ellsworth, MacAleese, & Cleveland, 2008; Smith & Churchill, 2002). (See the case example with Will later in this chapter for an illustration.) For example, growling may reliably signal aggression, in which case the analysis can be conducted using growling.

In addition to these variations of functional analysis, other methods of FBA can be used to inform the functional analysis process. Although these methods have sometimes been used as alternatives to functional analyses, we view them as valuable steps in the process, not as substitutes for a functional analysis.

Safety Considerations for FAs

When conducting FAs, the behavior analytic practitioner must consider ethical issues surrounding the client's safety. Kahng et al. (2015) noted that, in a retrospective study of 99 clients' functional analyses, the injury rate was relatively low and any injuries that did occur were mild. However, because target behaviors are expected to be evoked during FAs, it is important to implement precautionary measures to ensure the safety of all individuals involved. In particular, steps should be taken when analyzing potentially harmful behaviors, such as aggression, self-injurious behavior, and pica. Some procedures that have been used to mitigate risk of injury when assessing potentially dangerous behaviors are as follows: medical examinations to rule out health and physical concerns, presence of medical staff for especially severe behavior (Iwata 1982, 1994a), ensuring that trained practitioners plan and run analyses, having additional staff present to block behavior, using protective equipment, establishing a behavioral and/or medical criterion for terminating sessions (Kahng et al., 2015), using soft toys to conduct the analysis (Hanley, 2012), and using brief FA or assessing precursor behaviors (Najdowski et al., 2008; Smith & Churchill, 2002). Protective equipment can be utilized during the analysis as well; however, researchers have found the use of protective equipment can invalidate FA results (Borrero, Vollmer, Wright, Lerman, & Kelley, 2002; Le & Smith, 2002). (For a list of some other protections that can be taken, see Hanley, 2012, and Weeden, Mahoney, & Poling, 2010). Thus, although these precautions are often cited as recommendations, additional research is warranted to develop widely accepted evidence-based safety standards and best-practice guidelines.

Descriptive Functional Behavior Assessment

As with functional analyses, **descriptive functional behavior assessment** encompasses direct observation of behavior; unlike functional analyses, however, observations are made under naturally occurring conditions. Thus, descriptive assessments involve observation of the problem behavior in relation to events that are not arranged in a systematic manner. Descriptive assessments have roots in the early stages of applied behavior analysis; Bijou, Peterson, and Ault (1968) initially described a method for objectively defining, observing, and coding behavior and contiguous environmental events. This method has been used subsequently to identify events that may be correlated with the target behavior. Events that are shown to have a high degree of correlation with the target behavior may suggest hypotheses about behavioral function. We describe three variations of descriptive analysis: ABC (antecedent-behavior-consequence) continuous recording, ABC narrative recording, and scatterplots.

Before we describe the forms of descriptive assessment, we think it is important for the reader to consider some caveats. All of the forms of descriptive assessments explained below are generally considered invalid for detecting behavioral function. This is because they tend to yield false positives for an attention function. When an individual displays severe problem behavior, attention is often ubiquitous in the environment—attention is often delivered both independent of and contingent on problem behavior. In addition, false negatives can occur for escape-maintained problem behavior, because others in the environment may deliberately avoid making demands on an individual or placing the individual in any situations that trigger the problem behavior. Instead, the reader is cautioned to restrict conclusions based on descriptive assessments to only the prevalence of environmental factors that precede and follow the target behavior (Hanley, 2012).

ABC Continuous Recording

With ABC continuous recording, an observer records occurrences of the targeted problem behaviors and selected environmental events in the natural routine during a period of time. Codes for recording specific antecedents, problem behaviors, and consequences can be developed based on information obtained from a Functional Assessment Interview or ABC narrative recording (described later). For example, following an interview and observations using narrative recording, Lalli, Browder, Mace, and Brown (1993) developed stimulus and response codes to record the occurrence or nonoccurrence of antecedent (e.g., one-to-one instruction, group instruction) and subsequent events (attention, tangible reinforcement, escape) for problem behavior during classroom activities.

With ABC continuous recording, the occurrence of a specified event is marked on the data sheet (using partial interval, momentary time sampling, or frequency recording)

(see Figure 27.3). The targeted environmental events (antecedents and consequences) are recorded whenever they occur, regardless of whether problem behavior occurred with it. Recording data in this manner may reveal events that occur in close temporal proximity to the target behavior. For example, descriptive data may show that tantrums (behavior) often occur when a student is given an instruction to wash her hands (antecedent); the data may also show that tantrums are typically followed by the removal of task demands. A possible hypothesis in this situation is that tantrums are motivated by academic demands and are maintained by escape from those demands (negative reinforcement). (See the case example with Chris later in this chapter for an illustration.)

Advantages of ABC Continuous Recording. Descriptive assessments based on continuous recording use precise measures (similar to functional analyses), and in some cases the correlations may reflect causal relations (e.g., Alter, Conroy, Mancil, & Haydon, 2008; Sasso et al., 1992). Because the assessments are conducted in the context in which the problem

behaviors occur, they are likely to provide useful information for designing a subsequent functional analysis if that proves necessary. In addition, they do not require disruption to the person's routine.

Considerations for ABC Continuous Recording. Although descriptive analyses of this type may show a correlation between particular events and the problem behavior, such correlations can be difficult to detect in many situations. This is especially likely if the influential antecedents and consequences do not reliably precede and follow the behavior. In such cases, it may be necessary to analyze descriptive data by calculating **conditional probability** (the likelihood that a target problem behavior will occur in a given circumstance) or conducting a **contingency space analysis** (CSA, see Box 27.1).

However, conditional probabilities can be misleading. If a behavior is maintained by intermittent reinforcement, the behavior might occur often even though it is not followed consistently by a particular consequence. For example, the teacher might send the student to time-out only when tantrums are so frequent or severe that they are intolerable. In this case, only a small proportion of tantrums would be followed by that consequence, and the conditional probability would be low. One possibility, therefore, is that a functional relation that exists (e.g., tantrums negatively reinforced by escape) will not be detected. Furthermore, the child's current behavior intervention plan might require three repetitions of the instruction and an attempt to provide physical assistance before time-out is implemented. In that situation, the conditional probability of tantrums being followed by attention would be high. A descriptive analysis might, therefore, suggest a functional relation (e.g., tantrums positively reinforced by attention) that does *not* exist. Perhaps for these reasons, studies that have used conditional probability calculations to examine the extent to which descriptive methods lead to the same hypotheses as functional analyses have generally found low agreement (e.g., Lerman & Iwata, 1993; Noell et al., 2001).

ABC Narrative Recording

ABC narrative recording is a form of descriptive assessment that differs from continuous recording in that (a) data are collected only when behaviors of interest are observed, and (b) the

BOX 27.1

What Is Contingency Space Analysis?

by Nathan VanderWeele and Corinne Gist

Contingency spaces display the relationship between events in terms of the probability of one event (e.g., a particular consequence) given or not given another event (e.g., the presence or absence of a particular behavior) (Martens, DiGennaro, Reed, Szczech, & Rosenthal, 2008; Matthews, Shimoff, & Catania, 1987; Schwartz, 1989). For example, if Johnny yells out 13 times during 20 observation intervals and, as a result, the teacher removes him from the classroom following 2 of those occurrences, we would say that the probability of the teacher removing Johnny from the classroom was 2/13, or approximately 15% of occurrences (see raw data below in row, Escape/Present; columns B, B+C, and B+C/B).

Attention	B	B+C	B+C/B
Present	13	9	0.69
Absent	7	3	0.43
Escape	B	B+C	B+C/B
Present	13	2	0.15
Absent	7	3	0.43
Other	B	B+C	B+C/B
Present	13	2	0.14
Absent	7	1	0.17

However, identifying the probability of a behavior–consequence relation in isolation represents an incomplete analysis of the event. In addition to determining the probability of the occurrence of the consequence following the behavior, the probability of the consequence following the absence of the behavior should also be determined, (e.g., 43% per the raw data shown above in row, Escape/Absent; columns B, B+C, and B+C/B) with the resulting values compared in what is called a *contingency space analysis (CSA).*

Graphing conditional probabilities in the general operant contingency space reveals the degree of contingency between events and behavior (see Figure A below), which may address some of the limitations associated with ABC recordings. A CSA is conducted in the natural environment and does not require experimental manipulation of the consequences. Direct observation is used to identify the presence of a positive, negative, or neutral contingency between behavior and its consequences. The contingency is said to be "positive" if a specific consequence is more likely to occur after the behavior. The contingency is said to be "negative" if the consequence is less likely to occur following the behavior. For example, if Johnny yells out 13 times during an observation period and receives teacher attention following 9 of those instances, we would say that the consequence of teacher attention (c) was *more* likely to occur following yelling out (b), indicating a positive contingency for yelling out and teacher attention. Alternatively, if the teacher more frequently withholds attention (c) following yelling out (b), we would say that teacher attention is *less* likely to occur following the behavior. Thus, a negative contingency may exist, since the consequence is not likely to follow the behavior.

As previously mentioned, to determine the operant strength of a behavior–consequence relation, the probability of the consequence following the behavior *and* the

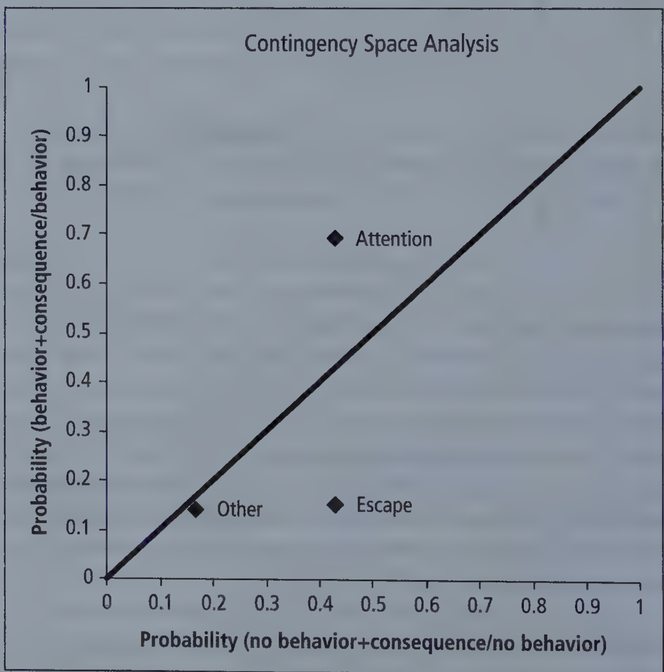

Figure A Hypothetical CSA data with graph illustrating potential positive (attention), negative (escape), and neutral (other) contingencies provides an example of a contingency space graph. The *y*-axis value equals the probability of a consequence given the occurrence of a behavior, and the *x*-axis value equals the probability of a consequence given the absence of a behavior.

probability of the consequence following the absence of behavior are calculated. To calculate the probability, the number of times the consequence followed the behavior is divided by the total number of behaviors emitted during an observation period, and the number of times the consequence occurred following the absence of the behavior is divided by the total number of intervals in which the behavior did not occur. These values are then plotted along the *x*-axis of the graph (see Figure A). The location of the resulting data point on the graph indicates the type and strength of the behavior–consequence relation. If the data point falls above and to the left of the line, a positive contingency may exist, suggesting that the consequence could be maintaining the behavior. If the data point falls below and to the right of the line, a negative contingency may exist, suggesting that the consequence is likely not maintaining the behavior. If data points fall on or near the neutrality line, no contingency is likely to exist, indicating that the consequence is equally likely to occur independent of the occurrence of behavior. Additionally, the greater the distance between the data point and the neutrality line, the stronger (positive) or weaker (negative) the hypothesized behavior–consequence relationship. It is important to note, however, that the efficacy of CSA results will rely heavily on the fidelity of the descriptive data collected.

recording is open-ended (any events that immediately precede and follow the target behavior are noted) (see Figure 3.3 in this text). Because data are recorded only when the target behavior occurs, narrative recording may be less time-consuming than continuous recording. However, narrative recording has several disadvantages in addition to those described earlier.

Considerations for Narrative Recording. Because narrative recording data are seldom reported in published research, their utility in identifying behavioral function has not been established. However, ABC narrative recording might identify functional relations that do not exist because antecedent and consequent events are recorded only in relation to the target behavior; it would not be evident from ABC data if particular events occurred just as often in the absence of the target behavior. For example, ABC data might erroneously indicate a correlation between peer attention and disruption even though peer attention also occurred frequently when the student was not disruptive.

Another potential limitation of ABC narrative recording concerns its accuracy. Unless observers receive adequate training, they may report inferred states or subjective impressions (e.g., "felt embarrassed," "was frustrated") instead of describing observable events in objective terms. In addition, given the likelihood that a number of environmental events occur in close temporal proximity to one another, discriminating the events that occasion a behavior can be difficult. Lerman, Hovanetz, Strobel, and Tetreault (2009) found that teachers collected ABC data more accurately when using a more structured format than with narrative recording. Thus, ABC narrative recording may be best suited as a means of gathering preliminary information to inform continuous recording or functional analyses.

Scatterplot Recording

Scatterplot recording is a procedure for recording the extent to which a target behavior occurs more often at particular times than others (Symons, McDonald, & Wehby, 1998; Touchette, MacDonald, & Langer, 1985). Specifically, scatterplots involve dividing the day into blocks of time (e.g., a series of 30-min segments). For every time segment, an observer uses different symbols on an observation form to indicate whether the target problem behavior occurred a lot, some, or not at all (see Figure 27.4). After data have been collected over a series of days, they are analyzed for patterns (specific time periods that are typically associated with problem behavior). If a recurring response pattern is identified, the temporal distributions in the behavior can be examined for a relation to particular environmental events. For example, a time period in which the behavior occurs often might be correlated with increased demands, low attention, certain activities, or the presence of a particular person. If so, changes can be made on that basis.

Considerations for Scatterplots. The primary advantage of scatterplots is that they identify time periods during which the problem behavior occurs. Such information can be useful in pinpointing periods of the day when more focused ABC assessments might be conducted to obtain additional information regarding the function of the problem behavior. Although scatterplots are often used in practice, little is known about their utility. It is unclear whether temporal patterns are routinely evident (Kahng et al., 1998). Another problem is that obtaining accurate data with scatterplots may be difficult (Kahng et al., 1998). In addition, the subjective nature of the ratings of how often the behavior occurs (e.g., "a lot" versus "some") can contribute to difficulties with interpretation (standards for these values might differ across teachers or raters).

Indirect Functional Behavior Assessment

Indirect functional assessment methods use structured interviews, checklists, rating scales, or questionnaires to obtain information from those who are familiar with the person exhibiting the problem behavior (e.g., teachers, parents, caregivers, and/or the individual himself or herself) to identify possible conditions or events in the natural environment that correlate with the

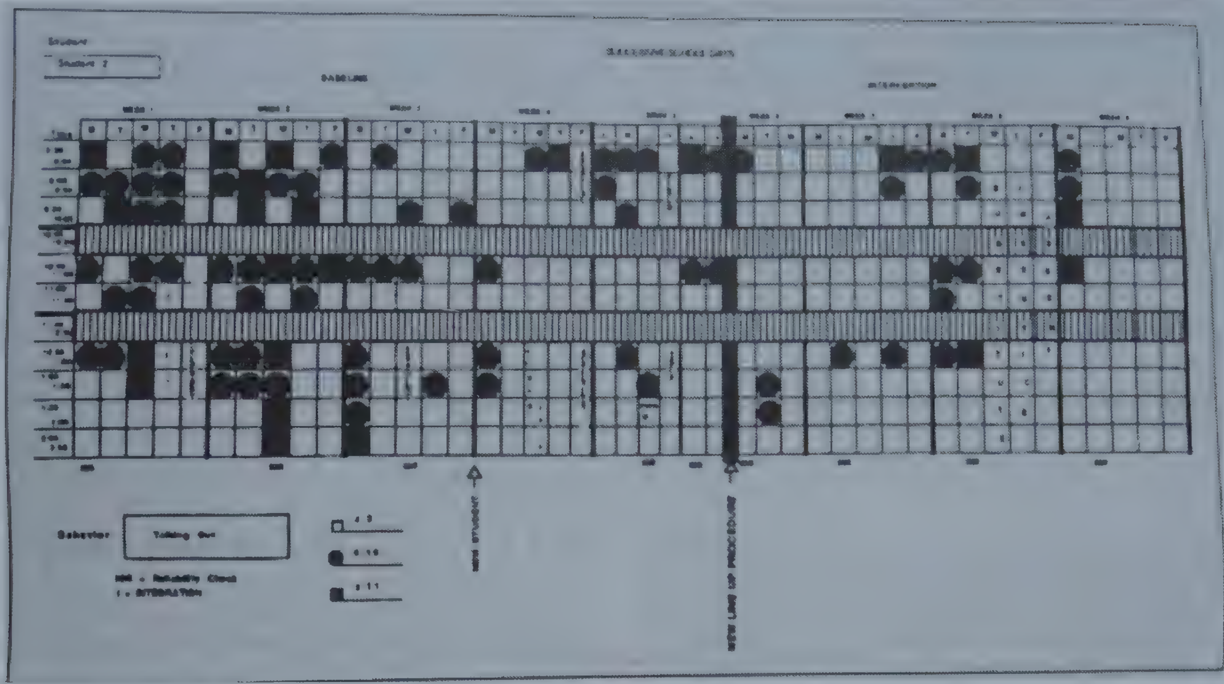

Figure 27.4 Example of scatterplot recording form. Different shapes represent different observed rates of talk-outs per daily observation intervals. Open squares, 2 or fewer talk-outs; shaded circles, 4–10 talk-outs; filled squares, 11 or more occurrences.

problem behavior. Such procedures are referred to as "indirect" because they do not involve direct observation of the behavior, but rather solicit information based on others' recollections of the behavior.

Behavioral Interviews

Interviews are used routinely in assessment. The goal of a behavioral interview is to obtain clear and objective information about the problem behaviors, antecedents, and consequences. This might include clarifying descriptions of the behavior (consequences); when (times), where (settings, activities, events), with whom, and how often it occurs; what typically precedes the behavior (antecedents); what the child and others typically do immediately following the behavior (consequences); and what steps have previously been taken to address the problem, and with what result. Similar information might be solicited about desirable behavior (or the conditions under which undesirable behavior does not occur) to identify patterns or conditions that predict appropriate versus problem behavior. Information can also be obtained about the child's apparent preferences (e.g., favorite items or activities), skills, and means of communicating. A skillful interviewer poses questions in a way that evokes specific, complete, and factual responses about events, with minimal interpretation or inferences.

Lists of interview questions have been published, and they provide a consistent, structured format for obtaining information through either an interview or a questionnaire format. For example, the Functional Assessment Interview (O'Neill et al., 1997) has 11 sections, which include description of the form (topography) of the behavior, general factors that might affect the behavior (medications, staffing patterns, daily schedule), antecedents and outcomes of the behavior, functional behavior repertoires, communication skills, potential reinforcers, and treatment history.

A form of the Functional Assessment Interview for students who can act as their own informants is also available (Kern, Dunlap, Clarke, & Childs, 1995; O'Neill et al., 1997). Questions include the behavior or behaviors that cause trouble for the students at school, a description of their class schedule and its relation to problem behavior, rating of intensity of behaviors on a scale of 1 to 6 across class periods and times of day, aspects of the situation related to the behavior (e.g., difficult, boring, or unclear material; peer teasing; teacher reprimands), other events that might affect the behavior (e.g., lack of sleep, conflicts), consequences (what occurs when the individuals engage in the behavior), possible behavior alternatives, and potential strategies for a support plan.

Two other questionnaires are the Behavioral Diagnosis and Treatment Information Form (Bailey & Pyles, 1989) and the Stimulus Control Checklist (Rolider & Van Houten, 1993), which also address questions about the conditions under which the behavior occurs or does not occur and how often. In addition, they include questions about physiological factors that might affect the behavior.

Behavior Rating Scales

Behavior rating scales designed for functional assessment ask informants to estimate the extent to which behavior occurs under specified conditions, using a Likert scale (e.g., *never, seldom, usually, always*). Hypotheses about the function of a behavior are based on the scores associated with each condition. Those conditions assigned the highest cumulative or average rating are hypothesized to be related to the problem behavior. For example, if an informant states that problem behavior always occurs when demands are placed on a child, a negative reinforcement hypothesis might be made. Table 27.2 summarizes features of several behavior rating scales.

Considerations for Indirect FBA

Some indirect assessment methods can provide a useful source of information in guiding subsequent, more objective assessments, and contribute to the development of hypotheses about variables that might occasion or maintain the behaviors of concern. Because indirect forms of FBA do not require direct observation of problem behavior, most behavior analytic practitioners view them as convenient and consider them useful in conducting an FBA. However, we caution readers that closed-ended indirect assessment instruments such as the MAS and QABF have been repeatedly demonstrated to be unreliable and therefore of questionable validity in identifying function (see Hanley, 2012).

CONDUCTING A FUNCTIONAL BEHAVIOR ASSESSMENT

FBA can best be viewed as a four-step process:

1. Gather information with indirect and descriptive assessment.
2. Interpret information from indirect and descriptive assessment and formulate hypotheses about the purpose of problem behavior.
3. Test hypotheses using functional analysis.
4. Develop intervention options based on the function of problem behavior.

Gathering Information

It is often helpful to begin the FBA process by conducting Functional Assessment Interviews with the person's teacher, parent, caregiver, and/or others who work closely with the person. The interview can be helpful in preparing the evaluator to conduct direct observations by identifying and defining the target problem behaviors, identifying and defining potential

TABLE 27.2 Behavior Rating Scales Used to Assess Possible Functions of Problem Behavior

Behavior rating scale	Functions assessed	Format and number of items	Example item and possible function
Motivation Assessment Scale (MAS) (Durand & Crimmins, 1992)	Sensory reinforcement, escape, attention, and tangible reinforcement	16 questions (4 for each of 4 functions), 7-point scale from *always* to *never*	Does the behavior seem to occur in response to your talking to other persons in the room? (attention)
Motivation Analysis Rating Scale (MARS) (Wieseler, Hanson, Chamberlain, & Thompson, 1985)	Sensory reinforcement, escape, and attention	6 statements (2 for each of 3 functions), 4-point scale from *always* to *never*	The behavior stops occurring shortly after you stop working or making demands on this person. (escape)
Problem Behavior Questionnaire (PBQ) (Lewis, Scott, & Sugai, 1994)	Peer attention, teacher attention, escape/avoid peer attention, escape/avoid teacher attention, and assessment of setting events	Questions, 7-point range	When the problem behavior occurs, do peers verbally respond to or laugh at the student? (peer attention)
Functional Analysis Screening Tool (FAST) (Iwata & DeLeon, 1996)	Social reinforcement (attention, preferred items), social reinforcement (escape), automatic reinforcement by sensory stimulation, automatic reinforcement by pain attenuation	Yes or no as to whether statements are descriptive	When the behavior occurs, do you usually try to calm the person down or distract the person with preferred activities (leisure items, snacks, etc.)? (social reinforcement, attention, preferred items)
Questions About Behavioral Function (QABF) (Paclawskyj, Matson, Rush, Smalls, & Vollmer, 2000)	Attention, escape, nonsocial, physical, tangible	Statements, 4-point range	Participant engages in the behavior to try to get a reaction from you. (attention)

antecedents and consequences that may be observed, and gaining an overall picture of the problem behavior as well as the strengths of the person. The interview can also help determine if other assessments are warranted before a more extensive FBA is conducted. For example, if the interview reveals that the person has chronic ear infections that are currently untreated, a medical evaluation should be conducted before further behavioral assessment takes place.

In many cases, conducting an interview with the person who has problem behavior can be helpful if he has the language skills to understand and respond to interview questions. Sometimes the person has useful insights regarding why he displays problem behavior in specific contexts.

At this point, conducting direct observations of the problem behavior within the natural routine is useful. Such observations help confirm or disconfirm the information obtained through the interviews. If it is not clear when the problem behavior occurs most often, a scatterplot analysis may be useful to determine when further behavioral observations should be conducted. When the problematic time periods have been determined, the behavior analyst can conduct ABC assessments. Information obtained from the interviews is helpful in guiding the ABC assessment because the evaluator should already have clear definitions of the target behavior(s), antecedents, and consequences. However, the behavior analyst must also watch for additional, unexpected antecedents and consequences that might present themselves in the natural environment. Teachers or caregivers sometimes overlook or are unaware of specific stimuli triggering or following problem behavior.

Interpreting Information and Formulating Hypotheses

Results from indirect assessments should be analyzed for patterns of behavior and environmental events so that hypotheses regarding the function of the problem behavior can be made. If problem behavior occurs most frequently when low levels of attention are available and problem behavior frequently produces attention, a hypothesis that attention maintains the problem behavior is appropriate. If the problem behavior occurs most frequently in high-demand situations and often produces a reprieve from the task (e.g., through time-out, suspension, or another form of task delay), then a hypothesis that escape maintains the problem behavior is appropriate. If problem behavior occurs in an unpredictable pattern or at high rates across the school day, a hypothesis that the behavior is maintained by automatic reinforcement may be appropriate. In reviewing assessment results and considering possible hypotheses, behavior analysts should remember that behaviors may serve multiple functions and different topographies of problem behavior may serve different functions.

Hypothesis statements should be written in ABC format. Specifically, the hypothesis statement should state the antecedent(s) hypothesized to trigger the problem behavior, the topography of problem behavior, and the maintaining consequence. An example is presented below:

Hypothesized Function	Antecedent	Behavior	Consequence
Escape from hand washing and/or lunch.	When Flo is prompted to wash her hands in preparation for lunch, . . .	she screams and falls to the ground, which is followed by . . .	termination of hand washing and lunch by being sent to time-out.

Writing hypothesis statements in this manner is useful because it requires the behavior analyst to focus on potential avenues for intervention: modifying the antecedent and/or modifying the reinforcement contingencies (which may involve teaching a new behavior and altering what behaviors are reinforced or placed on extinction).

Testing Hypotheses

After hypotheses have been developed, a functional analysis can be conducted to test them. The functional analysis should always contain a control condition that promotes the lowest frequency of problem behavior. Often this is the play condition, which consists of (a) continuous availability of preferred toys and/or activities, (b) no demands, and (c) continuously available attention. Then, conditions are selected to test specific hypotheses. For example, if the primary hypothesis is that the problem behavior is maintained by escape, then a contingent escape condition should be implemented. Other test conditions may not need to be implemented.

Being selective about the test conditions implemented will help keep the functional analysis as brief as possible; however, no conclusions can be made regarding additional functions of problem behavior if additional test conditions are not implemented. For example, if play and contingent escape are the only conditions tested, and problem behavior occurs most frequently in the contingent escape condition and seldom or never occurs in the play condition, the conclusion that escape maintains the problem behavior is supported. However, because a contingent attention condition was not implemented, one could not rule out the possibility that attention also maintains the problem behavior.

Developing Interventions

When an FBA has been completed, an intervention that matches the function of problem behavior can be developed. Interventions can take many forms. Although FBA does not identify which interventions will be effective in treating problem behavior, it does identify antecedents that may trigger problem behavior, potential behavioral deficits that should be remedied, and reinforcement contingencies that can be altered, as described earlier in this chapter. In addition, FBA *does* identify powerful reinforcers that can be used as part of the intervention package. The intervention should be **functionally equivalent** to problem behavior. That is, if problem behavior serves an escape function, then the intervention should provide escape (e.g., in the form of breaks from task demands) for a more appropriate response or involve altering task demands in a fashion that makes escape less reinforcing.

One effective way to design interventions is to review confirmed hypotheses to determine how the ABC contingency can be altered to promote more positive behavior. For example, consider the hypothesis developed for Flo, and assume the functional analysis revealed a pattern similar to that seen in the upper right-hand corner of Figure 27.2:

Hypothesized Function	Antecedent	Behavior	Consequence
Escape from hand washing and/or lunch.	When Flo is prompted to wash her hands in preparation for lunch, . . .	she screams and falls to the floor, which is followed by . . .	termination of hand washing and lunch by being sent to time-out.

The antecedent could be altered by changing the time of day when Flo is asked to wash her hands (so that it does not precede lunch, thereby decreasing the motivation for escape-motivated tantrums).

Hypothesized Function	Antecedent	Behavior	Consequence
Escape from hand washing and/or lunch.	Flo is prompted to wash her hands before recess.	N/A (Problem behavior is avoided.)	N/A (The consequence is irrelevant because problem behavior did not occur.)

The behavior could be altered by teaching Flo a new behavior (e.g., signing "break") that results in the same outcome (escape from lunch).

Hypothesized Function	Antecedent	Behavior	Consequence
Escape from hand washing and/or lunch.	When Flo is prompted to wash her hands in preparation for lunch, . . .	Flo is prompted to sign "break," which is followed by . . .	termination of hand washing and lunch.

Or, the consequences could be altered. For example, the reinforcer for problem behavior could be withheld so that problem behavior is extinguished.

Hypothesized Function	Antecedent	Behavior	Consequence
Escape from hand washing and/or lunch.	When Flo is prompted to wash her hands in preparation for lunch, . . .	she screams and tantrums, which is followed by . . .	continued presentation of hand washing and lunch activities.

An intervention can also consist of several different components. For example, Flo could be taught a replacement behavior (signing "break"), which results in breaks from lunch, while tantrums are simultaneously placed on escape extinction.

FBA can also help identify interventions that are likely to be ineffective or that may worsen the problem behavior. Interventions involving time-out, in-school or out-of-school suspension, or planned ignoring are contraindicated for problem behaviors maintained by escape. Interventions involving reprimands, discussion, or counseling are contraindicated for problem behaviors maintained by attention.

We offer a final word about intervention: When an intervention has been developed, FBA is not "done." Assessment is ongoing once intervention is implemented, as it is important for the continued monitoring of intervention effectiveness. The functions of behavior are not static. Rather, they are dynamic and change over time. Intervention may lose its effectiveness because the function of problem behavior may change (Lerman, Iwata, Smith, Zarcone, & Vollmer, 1994). In such cases, additional functional analyses may be needed to revise the intervention.

CASE EXAMPLES ILLUSTRATING THE FBA PROCESS

FBA is a highly idiosyncratic process. It is unusual for any two FBAs to be exactly the same because each person presents with a unique set of skills and behaviors, as well as a unique history of reinforcement. FBA requires a thorough understanding of behavioral principles to parcel out the relevant information from interviews and ABC assessments, to form relevant hypotheses, and to test those hypotheses. Beyond these skills, a solid understanding of behavioral interventions (e.g., differential reinforcement procedures, schedules of reinforcement, and tactics for promoting maintenance and generalization) is needed to match effective treatments to the function of challenging behavior. Furthermore, it is important for the practitioner to keep abreast of the current literature in functional analysis and treatment of problem behavior, because the evidence base is constantly evolving. This can seem like a daunting process. In an attempt to demonstrate the application of FBA across the idiosyncratic differences in people, we present an array of case examples that illustrate its utility in developing interventions that render the problem behavior ineffective, irrelevant, or inefficient.

Marie—Brief Functional Analysis

Gathering Information, Interpreting Information, and Forming Hypotheses

Marie was an 8-year-old girl with autism who had been referred to a behavior analyst for an evaluation of severe problem behavior, specifically aggression toward her family members. Her insurance covered 3 hours of "ABA therapy" per week, which she was receiving from a community mental health agency social worker. Her mother and sister attended every session.

The only behavior analyst with the skills necessary to consult on this case was 150 miles away at a local university, so the behavior analyst helped the agency staff conduct the functional analysis via teleconsultation.

The behavior analyst began by conducting a Functional Assessment Interview with Marie's mother, who reported that aggression occurred in a variety of settings, toward children and adults, and typically occurred when Marie did not get what she wanted, usually a preferred toy. Aggression also took place during her therapy sessions when the therapist was talking to Marie's mother, updating her on the session. However, aggression toward her on-site therapist had recently decreased. The behavior analyst then collected some ABC data during a play session with Marie's mother and younger sister, as well as during her ABA therapy session at the clinic. The ABC data showed a pattern of aggression when Marie's preferred items were removed. In addition, the ABC data indicated that the consequence that most often followed aggression was Marie's mother or sister relinquishing the item back to Marie. Based on the descriptive data, it was hypothesized that Marie's aggression could be maintained by access to tangibles.

Testing Hypotheses

Due to the limited number of hours per week Marie received services, a brief functional analysis was conducted to determine the function of Marie's aggression. The consulting behavior analyst trained Marie's therapist to conduct the assessment via teleconsultation, and was available during the assessment to provide coaching and feedback. Four 5-min functional analysis conditions (free play, attention, demand, and tangible) were conducted, and aggression occurred only in the tangible condition. During each session, the behavior analyst scored the occurrence of problem behavior using a 10-sec partial interval recording procedure. During the contingency reversal, the number of requests was also recorded. The functional analysis results are shown in Figure 27.5. After the first four conditions, the behavior analyst coached the on-site therapist on how to implement functional communication training (FCT) to teach Marie to ask for the tangible item. This was selected as a replacement behavior because it matched the function of the problem behavior and could efficiently compete for the reinforcer. During three 5-min training sessions, requests increased and aggression dropped to zero. The behavior analyst instructed the on-site therapist to conduct a contingency reversal by implementing a second tangible functional analysis condition. During this reversal, aggression increased to 50% of intervals, and requesting decreased from 11 to 2 occurrences. Upon reinstatement of FCT, aggression returned to zero and requesting returned to the previous treatment level. All functional analysis and treatment conditions were completed in a 60-min appointment with Marie's therapist, mother, and sister present.

Developing an Intervention

During the brief FA, functional communication training (FCT; teaching appropriate requesting) was shown to be an effective treatment for decreasing aggression. It matched the function and was more efficient than the problem behavior in obtaining access

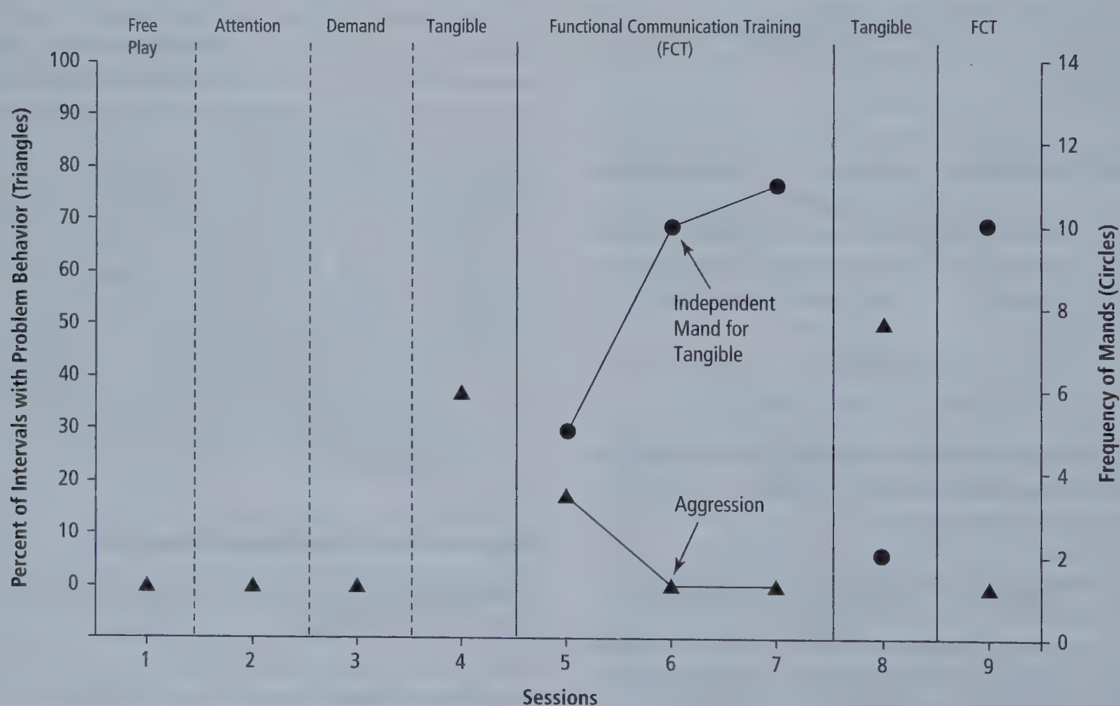

Figure 27.5 Results from the brief functional analysis for Marie. The graph depicts the percentage of 10-sec intervals in which problem behavior occurred (left *y*-axis) and the number of independent mands (right *y*-axis) in each condition.

Marie's case example contributed by Rebecca Eldrige and Nathan VanderWeele.

to the tangible item. During a follow-up meeting, the behavior analyst, the on-site therapist, and Marie's mother met to develop the treatment plan. Marie's mother was concerned about the times that she would need to say "no" to Marie when Marie was asking for preferred items and was worried that aggression would result. The behavior analyst worked with the team to develop a treatment plan that included initially delivering the item each time Marie requested it until aggression had decreased to zero for three consecutive 30-min sessions. When Marie was regularly making requests without aggression, a program to teach waiting for the preferred item was introduced. To gain access to the preferred item, Marie had to wait (without aggression) for 1 to 60 seconds after requesting it. Once waiting was mastered, Marie was taught to complete a task while while waiting. She could then earn the preferred item only after the task was complete. The behavior analyst and on-site therapist then taught Marie's mother to implement the procedure, which she did successfully.

Carson—Trial-based Functional Analysis

Gathering Information, Interpreting Information, and Forming Hypotheses

Carson, a 10-year-old boy with a chromosomal deletion disorder, was receiving special education services in the general education classroom. He displayed several problem behaviors—most notably, talking to peers during group instruction, yelling out answers, and running around the room. These behaviors occurred only in the general education classroom. They had increased in intensity, resulting in more time spent in the resource room, away from the general education setting. Consequently, Carson was missing valuable instruction time and falling behind in the curriculum.

The behavior analyst assigned to Carson's case was asked to complete an FBA in order to design an intervention plan that would increase the time he spent in the general education classroom and decrease his disruptive behavior. After obtaining consent from Carson's parents to conduct an FBA, the behavior analyst conducted a Functional Assessment Interview with Carson's teachers and paraprofessionals. From the interview, it appeared that Carson's problem behaviors occurred most often during group lessons on the carpet and individual work at his desk. Carson's teachers and paraprofessionals could not identify a clear pattern of consequences for his behavior because they had tried so many different strategies without success. Following the interview, the behavior analyst used a structured data form to begin collecting ABC data during those times reported as most problematic by the teachers. The ABC assessment showed that escape from demands or access to one-on-one attention could be maintaining Carson's disruptive behavior.

Testing Hypotheses

At this point, the behavior analyst needed to test her hypotheses, but she had several reservations about conducting a traditional FA in the classroom setting. She was concerned about the time that a traditional FA would take as well the teacher's ability to implement it with a high degree of fidelity while also teaching. For these reasons, the behavior analyst decided to conduct a trial-based functional analysis (TBFA) on disruptive behavior, with the teacher implementing the conditions. Four conditions were conducted: attention test, attention control, escape test, and escape control. During the attention test condition, teacher attention was diverted unless Carson engaged in disruption. If he engaged in disruption, the teacher provided attention for 10 seconds and ended the trial. During the attention control condition, attention was delivered every 5 seconds for 60 seconds, with no programmed consequences for disruptive behavior. During the escape test condition, the teacher worked one-on-one with Carson, repeatedly prompting him to complete his work. If he engaged in disruption, the teacher walked away and removed task demands for 10 seconds. During the escape control condition, the teacher provided a 1-min break with no attention or task demands and no programmed consequences for disruption. Each condition was implemented 8 times (trials) for 1 min during regular instruction throughout the school day. The percentage of trials with disruption in each condition was then calculated and graphed. The results (see Figure 27.6) showed that disruption occurred most often in the attention

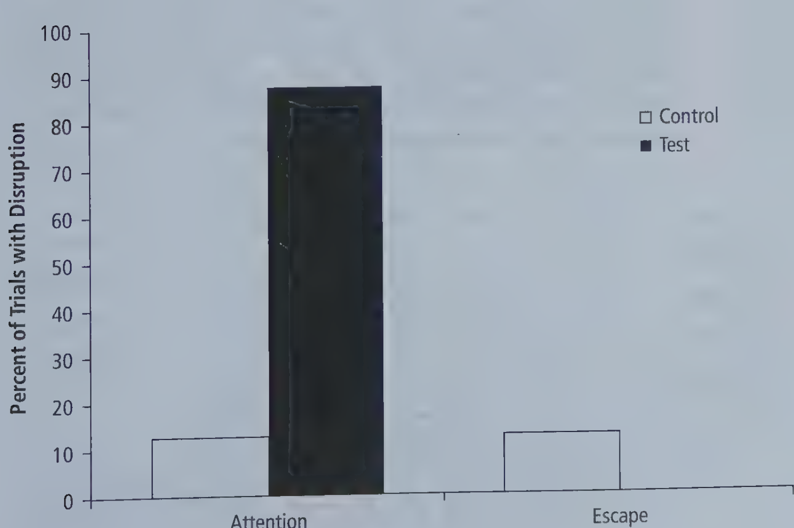

Figure 27.6 Results from the trial-based functional analysis for Carson. The graph shows the percentage of trials, for both the control and the test conditions, in which disruptive behavior occurred.

Carson's case example contributed by Rebecca Eldrige and Nathan VanderWeele.

test condition, and thus supported the hypothesis that attention was maintaining disruptive behavior. In addition, the escape test condition evoked no problem behavior, which suggested that escape from demands was not a reinforcing variable for disruptive behavior.

Developing an Intervention

Based on the results of the trial-based functional analysis, a multicomponent treatment plan was developed that included discontinuing attention when Carson engaged in disruptive behavior, teaching him to raise his hand to gain attention, and providing contingent breaks with teacher attention for sitting quietly at his desk for increasing amounts of time. Thus, problem behavior was placed on extinction, and more appropriate behaviors (hand raising and sitting quietly engaged in his work) produced teacher attention.

Elija—Latency-based Functional Analysis

Gathering Information, Interpreting Information, and Forming Hypotheses

Elija was a 9-year-old boy diagnosed with autism spectrum disorder. He engaged in elopement and noncompliance and was referred to a behavior analyst for a functional analysis.

The behavior analyst began with a Functional Assessment Interview (O'Neill et al., 1997) with Elija's mother. Elija's mother reported that he typically engaged in elopement in the community as well as in the home; he would run out of the home or store and into the street when he wanted something he couldn't have (while in the community) or when he was denied access to his toys (at home). Consequently, his mother did not take him out much, which limited the number of activities Elija could engage in throughout the day. His mother kept all the doors locked in the house.

Next, the behavior analyst conducted some direct observation of Elija's behavior at home using remote technology. Elija's mother was observed working with him under a variety of naturally occurring conditions. The behavior analyst took data on elopement attempts as well as the immediate antecedents and consequences. Attempts to elope were blocked to keep Elija safe. During the ABC assessment, the behavior analyst observed elopement attempts when Elija was asked to complete academic tasks. Additionally, when he eloped, Elija's mother provided extensive attention in an attempt to get him to sit back down at the table and do his work. Based on the ABC observations, the behavior analyst hypothesized that Elija's elopement was maintained by escape from task demands as well as access to tangible items, and attention.

Testing Hypotheses

The functional analysis was conducted at the center where Elija received services. The behavior analyst decided to conduct a latency-based functional analysis. She chose this assessment given the dangerous nature of the problem behavior. That is, she wanted to minimize the number of occurrences of elopement, and staff had to intervene when elopement did occur. The behavior analyst immediately reinforced elopement, which prevented Elija from eloping too far from the setting. Elopement was defined as any instance of Elija moving more than 3 feet away from the instructional setting and/or from an adult without permission. In addition to conducting the latency FA, the behavior analyst also ensured that additional therapists were assigned to all exits in the building to prevent Elija from going out of the building. The FA consisted of the following conditions: tangible, play (control), attention, and demand. The behavior analyst started a stopwatch when the condition began and let it run until elopement occurred. When elopement occurred, the behavior analyst stopped the stopwatch and recorded the time that had elapsed. This was the latency to elopement. The results of the FA are shown in Figure 27.7. The graph depicts that elopement was maintained by escape from demands and access to attention, because Elija's latency to elopement was shortest during the escape and attention conditions.

Developing an Intervention

It can be challenging when elopement or any other dangerous problem behavior serves an attention function, because the problem behavior cannot be placed on extinction (i.e., ignored) safely. The problem behavior will likely always result in at least some attention. Such was the case for Elija. As a result, the behavior analyst designed an intervention based on concurrently available reinforcement contingencies. When Elija was presented with a task demand, he was asked to make a choice from among three concurrently available options, which were signaled by three different colors (green, yellow, and red). Green was associated with Elija completing the assigned task demand. If he appropriately completed the task, he was given a high-quality break for 60 seconds. During his break, he received attention from his mother, as well as preferred toys. If he asked for a break from the

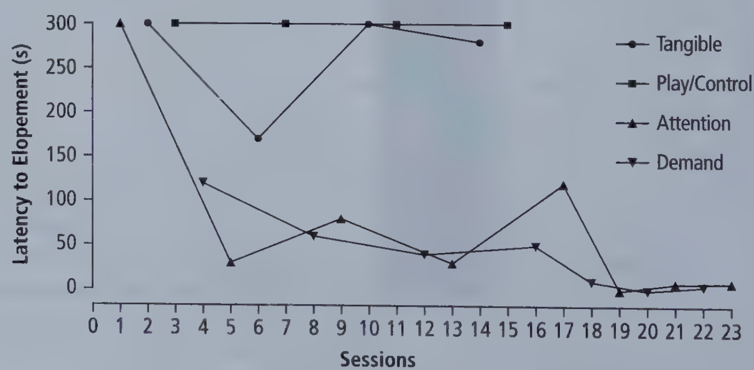

Figure 27.7 The latency to elopement for each condition in the FA for Elija. Note that elopement never occurred in the Play/Control condition; thus, the data points are plotted at 300 s, which represents the entire session duration (5 min). The latency was shortest during the attention and demand conditions, indicating escape and attention functions.

Elija's case example contributed by Denice Rios and Nicole Hollins.

task (the yellow option), he was given a task break. However, the break lasted only 30 seconds, he had access to less preferred toys, and his mother stayed with him for only a few seconds. If he engaged in elopement (the red option), he escaped the task for 10 seconds, no toys were available, and his mother neutrally blocked his egress from the room. Over time, the duration of the task demand to earn the high-quality break increased until Elija reliably engaged in the task demand rather than eloping.

Will—Evaluating Precursor Behavior

Gathering Information, Interpreting Information, and Forming Hypotheses

Will was 14 years old with a primary diagnosis of autism. He was quite large for his age and displayed high levels of physical aggression, verbal outbursts, and urinating on people. As a result of the severity and frequency of his problem behaviors, his size, a lack of informed treatment, and limited resources, Will was sent to a high-security juvenile detention center, where he was exposed to individuals without diagnosed disabilities who had committed violent, serious, and/or gang-related crimes. The county serving Will recognized that the juvenile detention center was not an appropriate placement for him but had no other placement options. As a last resort, the service coordinator on the case sought a behavior analytic consultation.

Upon getting involved with the case, the behavior analyst realized that everyone working with Will was skeptical that anything would help. The behavior analyst conducted an FBA interview with individuals who had worked with Will in the detention center. Because the center was a lock-down facility, the staff could not give much information about how Will performed in a variety of conditions. The interview yielded little useful information. Also, observations of natural routines were limited due to the nature of the placement. As a result, no formal descriptive assessments were completed. The behavior analyst proposed a functional analysis, but one of Will's caseworkers was concerned that once Will got upset, he would engage in aggression for hours. She was also concerned that Will's behaviors were so severe that allowing them to occur even once could be dangerous.

Based on a review of Will's records and the limited information available, it was hypothesized that Will's aggressive behaviors were maintained by escape from demands or by attention. In addition, it was determined that verbal outbursts describing the aggressive behavior he was about to engage in (e.g., "I'm going to piss on you!") reliably preceded Will's aggression. As a result of all these factors, it was decided that the functional analysis would be conducted on Will's verbal outbursts rather than on his aggression.

Testing Hypotheses

The functional analysis consisted of four conditions: tangible, free play, escape, and attention. In each of these conditions, occurrences of verbal outbursts were recorded using a 10-sec partial interval measurement system and plotted as the percentage of intervals with problem behavior (see Figure 27.8). Will displayed high levels of verbal outbursts during the tangible condition. The behavior analyst noted that Will's verbal outbursts could be interrupted if the therapist provided attention or task demands (i.e., the attention and demand conditions that followed the tangible condition) that redirected Will's behavior to some form of independent work.

Developing an Intervention

Based on the results of the functional analysis, the behavior analyst recommended that Will receive training in effectively and appropriately asking for tangible items. In addition, it was recommended that the training focus on teaching Will to tolerate delays in getting access to those tangible items. In his typical environment (e.g., school and home setting), gaining immediate access to tangible items was not always going to be feasible, so tolerating delays would be imperative for Will's success. Thus, a structured treatment that involved providing access to tangible items following appropriate requests, but not verbal outbursts, was recommended. After Will reliably requested items in an appropriate way, the behavior analyst slowly built in delays to the preferred item and asked Will to work on an independent task while waiting. Following appropriate waiting, Will received access to the preferred item. After observing the process, Will's caseworker—albeit initially resistant—considered that Will could live in a less restrictive environment.

Chris—Evaluating ABC Data

Gathering Information, Interpreting Information, and Forming Hypotheses

Chris was a 37-year-old man diagnosed with intellectual disabilities who lived in a group home. He had a limited vocal verbal repertoire and he used a wheelchair for mobility. Chris displayed

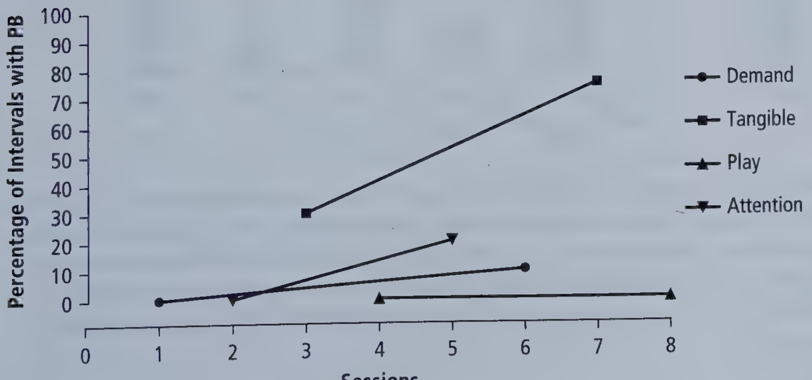

Figure 27.8 Results of Will's functional analysis of precursor behavior (verbal outbursts).

Will's case example contributed by Cody Morris, Denice Rios, and Lloyd Peterson.

frequent screaming toward caregivers and peers across many locations, including his home, various day programs, and outings. Interviews with staff members indicated that the screaming occurred throughout the day, but most frequently at his day programs. The staff hypothesized that the screaming occurred when Chris observed other roommates getting attention from staff. The behavior analyst also noticed that when staff members moved Chris's wheelchair, they often did so by walking up behind him and moving his wheelchair without saying anything to Chris about what was going to happen. This seemed to startle Chris, and the behavior analyst wondered if his screaming might also be maintained by avoidance of being removed from a specific area in the day program.

Structured ABC observations (similar to that in Figure 27.3) and narrative recordings (providing descriptors of each event) were conducted across various times in Chris's home and day programs. Both inappropriate vocalizations (screaming) and appropriate vocalizations were tracked. After data were collected, each antecedent and consequence entry was coded into categories, such as attention, presentation or removal of a demand, being relocated, and alone. Each occurrence of appropriate and inappropriate vocalization was then analyzed to determine what category of antecedent immediately preceded it and what category of consequence followed it. The percentage of both appropriate and inappropriate vocalizations preceded or followed by each category of variables was then graphed and analyzed using methods described in Chapter 6. The results are shown in Figure 27.9.

Based on the ABC observations and graphed ABC data, it was hypothesized that Chris's screaming served an attention function. The graphed data clearly showed that the most common antecedent variable that preceded both appropriate and inappropriate vocalizations was Chris being alone. However, Chris rarely received attention following appropriate attempts to interact with staff. In contrast, he reliably received staff attention following screaming. In fact, Chris was about twice as likely to receive attention for inappropriate vocalizations as for appropriate ones. Moreover, the narrative aspect of the ABC recording (see Table 27.3) indicated that staff members reliably ignored Chris while he scrolled through a wide variety of appropriate vocalizations (e.g., "hi," "how are you") that escalated to grunting and eventually screaming. Typically, it wasn't until Chris began screaming that he received high-quality attention from staff.

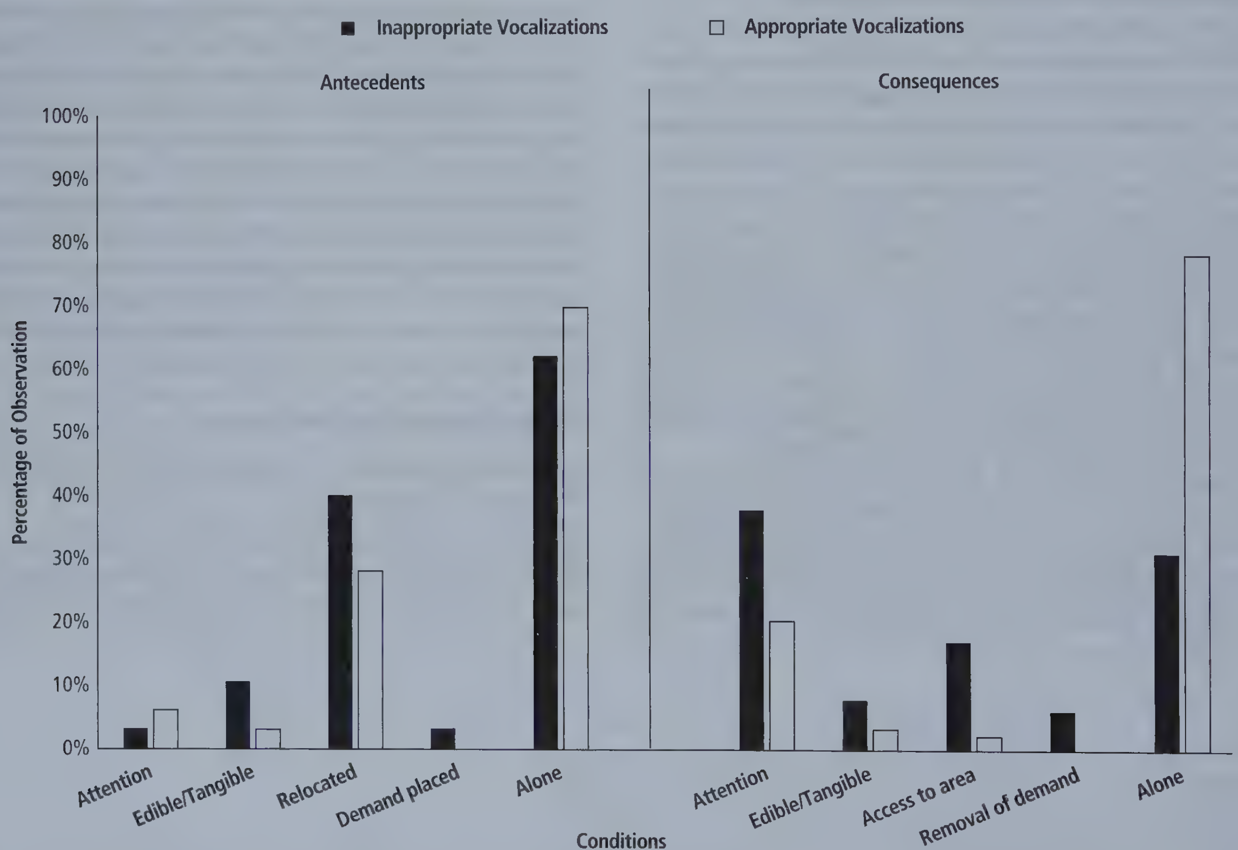

Figure 27.9 Results of Chris's ABC assessment. The left-hand panel shows the percentage of appropriate and inappropriate vocalizations that were preceded by the antecedent variables of one-on-one attention, access to edibles/tangibles, having someone move his wheelchair (relocated), having a demand placed on him, or being left alone. The right-hand panel shows the percentage of appropriate and inappropriate vocalizations that were followed by the consequence variables of one-on-one attention, access to edibles/tangibles, having access to a new area, having a demand removed, or being left alone.

Case example contributed by Cody Morris and Becky Kolb.

TABLE 27.3 Results of ABC Narrative Assessment for Chris's Appropriate and Inappropriate Behavior

Antecedent	Behavior	Consequence
Chris alone	Said "hi you"	Ignored by staff
Chris alone	Said "a ba" while pointing to a book	Ignored by staff
Chris alone	Screamed	Approached and told "Please stop screaming" and asked "What's wrong, Chris?"
Chris transitioned to a new activity (sorting)	Screamed	Staff asked Chris why he was upset—"Chris, what do you need?"
Chris transitioned to a different room (because of an event occurring)	Said "are you my boy" to staff while walking	Ignored by staff

Developing an Intervention

Because the ABC analysis identified a very apparent issue with staff interaction with Chris, it was not clear that a functional analysis was necessary. The behavior analyst wanted to first try having staff attend to appropriate behavior that Chris was already displaying. The intervention consisted of reversing staff's differential reinforcement of the inappropriate vocalizations. This was done by having staff reinforce the appropriate vocalizations (i.e., responding to the appropriate bids for attention) while placing screaming on extinction. In addition, because Chris engaged in high levels of appropriate vocalizations already, he was taught to tolerate a delay to reinforcement. Staff members were asked to acknowledge his requests and to provide reinforcement (attention) immediately, whenever possible. However, staff members were also taught to work directly with Chris to teach him to "wait" when necessary by slowly increasing delays to attention following their acknowledgement of his request. Finally, because Chris's vocalizations were somewhat difficult to understand and limited in variety, interventions to expand and improve the quality of Chris's mand repertoire were introduced.

Brian—Multiple Functions of Problem Behavior

Gathering Information

Brian was 13 years old and diagnosed with pervasive developmental delay, oppositional defiant disorder, and attention-deficit hyperactivity disorder. He had moderate delays in cognitive and adaptive skills. Brian displayed several problem behaviors, including aggression, property destruction, and tantrums. Brian's aggression had resulted in several of his teachers having bruises, and his property destruction and tantrums frequently disrupted the daily activities of the classroom.

A Functional Assessment Interview (O'Neill et al., 1997) was conducted with Brian's teacher, Ms. Baker, who reported that Brian's problem behavior occurred most frequently when he was asked to perform a task that required any kind of physical labor (e.g., shredding papers) and occurred least during leisure activities. However, Ms. Baker reported that Brian often engaged in problem behavior when he was asked to leave a preferred activity. She noted that Brian used complex speech (sentences), although he often used verbal threats, curse words, and/or aggression, property destruction, and tantrums to communicate his wants and needs.

Because Brian had a spoken repertoire, a Student-Assisted Functional Assessment Interview (Kern et al., 1995) was also conducted. In this interview, Brian reported that he found his math work too difficult but that writing and using a calculator were too easy. He reported that he sometimes received help from his teachers when he asked for it, that sometimes teachers and staff noticed when he was doing a good job, and that he sometimes received rewards for doing good work. Brian indicated that his work periods were always too long, especially those that consisted of shredding papers. Brian reported that he had the fewest problems in school when he was allowed to answer the phone (his classroom job), when he was completing math problems, and when he was playing with his Gameboy. He stated that he had the most problems at school when he was outside playing with the other students because they often teased him, called him names, and cursed at him.

An ABC assessment was conducted on two separate occasions. The results of the ABC assessment are shown in Table 27.4.

Interpreting Information and Formulating Hypotheses

Based on the interviews and ABC assessments, the function of Brian's problem behavior was unclear. It was hypothesized that some of Brian's problem behaviors were maintained by access to adult attention and preferred items. This hypothesis was a result of the ABC assessment, which indicated that many of Brian's problem behaviors occurred when adult attention was low or when access to preferred items was restricted. Brian's problem behavior often resulted in access to adult attention or preferred activities. It was also hypothesized that Brian's problem behavior was maintained by escape because his teacher reported that Brian frequently engaged in problem behavior in the presence of task demands and because Brian reported that some of his work was too hard and work periods lasted too long. Thus, a functional analysis was conducted to test these hypotheses.

Testing Hypotheses

The functional analysis consisted of the same conditions as described previously, with two exceptions. First, an alone condition was not conducted because there was no reason to believe that Brian's problem behavior served an automatic function. Second, a contingent tangible condition was added because there was reason to believe Brian engaged in problem behavior to gain access to preferred tangibles and activities.

TABLE 27.4 Results of ABC Assessments for Brian's Aggression, Property Destruction, and Tantrums

Antecedent	Behavior	Consequence
Adult attention diverted to another student; denied access to Nintendo by teacher (i.e., told no when he asked if he could play it)	Yelled at teacher, "That's not fair! Why do you hate me?!"	Told to "calm down"
Teacher attending to another student	Hit sofa, attempted to leave classroom	Given choice of activity and verbal warning to stay in classroom
Teacher attention diverted to another student	Yelled "Stop!" at another student	Reprimand from teacher: "Don't worry, Brian. I will take care of it."
Story time, teacher attending to other students	Laughed loudly	Reprimand from teacher: "Stop it!"
Story time, teacher listening to other students	Interrupted other students while they were talking: "Hey, it's my turn. I know what happens next!"	Reprimand from teacher: "You need to listen."

This condition was just like the play condition (i.e., Brian had access to adult attention and preferred toys at the beginning of the session), except that intermittently throughout the session, he was told it was time to give his toy to the teacher and to play with something else (which was less desirable). If Brian complied with the request to give the toy to the teacher, he was given a less preferred toy. If he engaged in problem behavior, he was allowed to continue playing with his preferred toys for a brief period.

The results of the functional analysis are shown in Figure 27.10. Notice that problem behavior never occurred in the play condition when continuous attention and preferred items were available and no demands were placed on Brian. However, it occurred at high rates in all three of the test conditions (contingent attention, escape, and tangible). These results indicated that Brian's problem behavior was maintained by escape, attention, and access to preferred items.

Developing an Intervention

Based on the results of the functional analysis, a multicomponent intervention was implemented. The intervention components changed at different points in time, depending on the context. For example, when Brian was engaged in a work task, it was recommended that he be given frequent opportunities to request breaks. In addition, the time-out intervention that the teacher had been using was discontinued in the work context. During leisure times, when Brian had previously been expected to play alone, the classroom schedule was rearranged so that Brian could play and interact with peers. Brian was also taught to request toys appropriately while playing with peers. In addition, several interventions aimed at increasing teacher attention for appropriate behavior were implemented. Brian was taught how to request teacher attention appropriately, and teachers began to respond to these requests rather than ignoring them, as they had been doing. In addition, a self-monitoring plan was established, in which Brian was taught to monitor his own behavior and to match his self-recordings to the recordings of his teachers. Accurate self-recording resulted in teacher praise and access to preferred activities with the teacher. Brian's teachers also implemented their own plan to increase attention and praise every 5 minutes as long as Brian was not engaged in problem behavior during independent work.

Lorraine—Multiple Topographies That Serve Multiple Functions

Lorraine was 32 years old and functioned in the moderate range of intellectual disability. She had a diagnosis of Down syndrome and bipolar disorder with psychotic symptoms, for which Zoloft

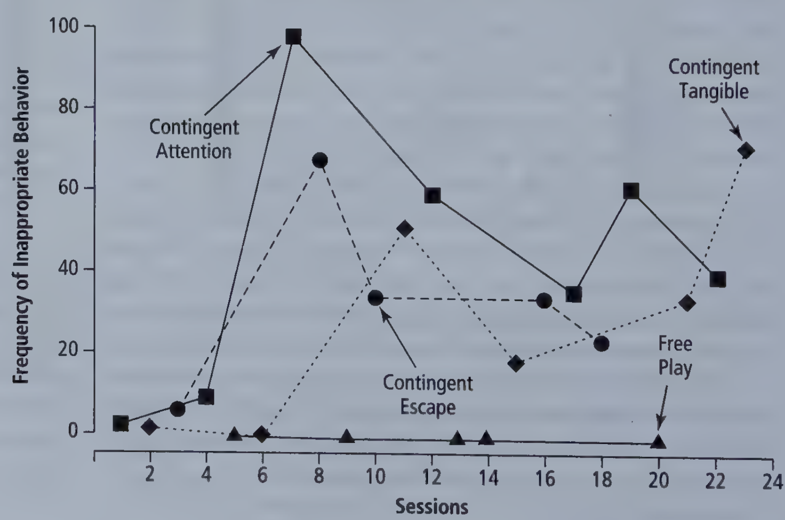

Figure 27.10 Results of Brian's functional analysis. Inappropriate behavior consists of aggression, property destruction, and tantrums.

Based on Brian's functional analysis conducted by Renee Van Norman and Amanda Flaute.

(sertraline) and Risperdal (risperidone) were prescribed. She also took Tegretol (carbamazepine) for seizure control. Her verbal skills were low and her articulation was poor. She communicated through some signs, a simple communication device, gestures, and some words.

Lorraine had resided in a group home for 9 years and attended a sheltered workshop during the day. Lorraine displayed noncompliance, aggression, and self-injurious behavior (SIB) in both settings, but the FBA focused on her problem behavior in the group home, where it was more severe and frequent. Noncompliance consisted of Lorraine putting her head down on the table, pulling away from people, or leaving the room when requests were made of her; aggression consisted of kicking others, throwing objects at others, biting others, and squeezing others' arms very hard; SIB consisted of biting her arm, pulling her hair, or pinching her skin.

Gathering Information

Interviews were conducted with Lorraine, her parents, and workshop and group home staff. Lorraine's parents noted that some of her behavior problems had increased when changes in her medication had been made. Workshop staff noted that Lorraine was more likely to have problem behavior at work if many people were around her. Workshop staff had also noted that noncompliance had increased shortly after a dosage change in medication 2 months previously. The group home staff members noted that they were most concerned about Lorraine's leaving the group home when she was asked to perform daily chores. Lorraine would often leave the group home and not return until the police had picked her up. Many neighbors had complained because Lorraine would sit on their porches for hours until the police came and removed her.

An ABC assessment was conducted at the workshop and group home to determine whether environmental variables differed across the two settings (e.g., the manner in which tasks were presented, the overall level of attention). At the workshop, Lorraine was engaged in a jewelry assembly task (one she reportedly enjoyed), and she worked well for $2\frac{1}{2}$ hours. She appeared to work better when others paid attention to her and often became off task when she was ignored; however, no problem behavior was observed at work. At the group home, aggression was observed when staff ignored Lorraine. No other problem behavior occurred. No demands were placed on Lorraine in the group home during the ABC observation. Group home staff rarely placed any demands on Lorraine in an attempt to avoid her problem behavior.

Interpreting Information and Formulating Hypotheses

Some of Lorraine's problem behaviors seemed to be related to a dosage change in her medication. Because Lorraine's physician judged her medication to be at therapeutic levels, a decision was made to analyze the environmental events related to her problem behavior. Observations of problem behavior during the ABC assessment were limited because workshop staff placed minimal demands on Lorraine to avoid problem behaviors. However, Lorraine's noncompliance reportedly occurred when demands were placed on her. Therefore, it was hypothesized that these problem behaviors were maintained by escape from task demands. Aggression occurred during the ABC assessment when Lorraine was ignored. Although SIB was not observed during the ABC assessment, group home staff reported that Lorraine often engaged in SIB during the same situations that evoked aggression. Therefore, it was hypothesized that both aggression and SIB were maintained by attention.

Testing Hypotheses

The functional analysis consisted of free play, contingent attention, and contingent escape conditions (see Figure 27.11). Because the problem behaviors may have served different functions, each problem behavior was coded and graphed separately. Noncompliance occurred most frequently during the contingent escape condition and rarely occurred during the free play or contingent attention condition. SIB occurred most frequently during the contingent attention condition and rarely occurred during the free play or contingent escape condition. These data suggested that noncompliance served an escape function and SIB served an attention function. As is often the case for low-frequency, high-intensity behaviors, it was difficult to form hypotheses about the function of aggression because the behavior occurred rarely in any of the FBA conditions.

Developing an Intervention

Different interventions were developed for the problem behaviors because results of the FBA suggested that the behaviors served different functions. To address noncompliance, Lorraine was taught to request breaks from difficult tasks. Tasks were broken down into very small steps. Lorraine was presented with only one step of a task at a time. Each time a task request was made, Lorraine was reminded that she could request a break (either by saying "Break, please" or by touching a break card). If she requested a break, the task materials were removed for a brief period. Then they were presented again. Also, if Lorraine engaged in noncompliance, she was *not* allowed to escape the task. Instead, she was prompted through one step of the task, and then another step of the task was presented. Initially, Lorraine was allowed to completely escape the task if she appropriately requested a break each time the task was presented. Over time, however, she was required to complete increasing amounts of work before a break was allowed.

Intervention for aggression consisted of teaching Lorraine appropriate ways to gain attention (e.g., tapping someone on the arm and saying, "Excuse me") and teaching group home staff to regularly attend to Lorraine when she made such requests. In addition, because her articulation was so poor, a picture communication book was created to assist Lorraine in having conversations with others. This communication book could be used to clarify words that staff could not understand. Finally, staff members were encouraged to ignore Lorraine's SIB when it did occur. In the past, staff had approached Lorraine and stopped her from engaging in SIB when it occurred. The functional analysis demonstrated that this intervention may have increased the occurrence of SIB, so this practice was discontinued.

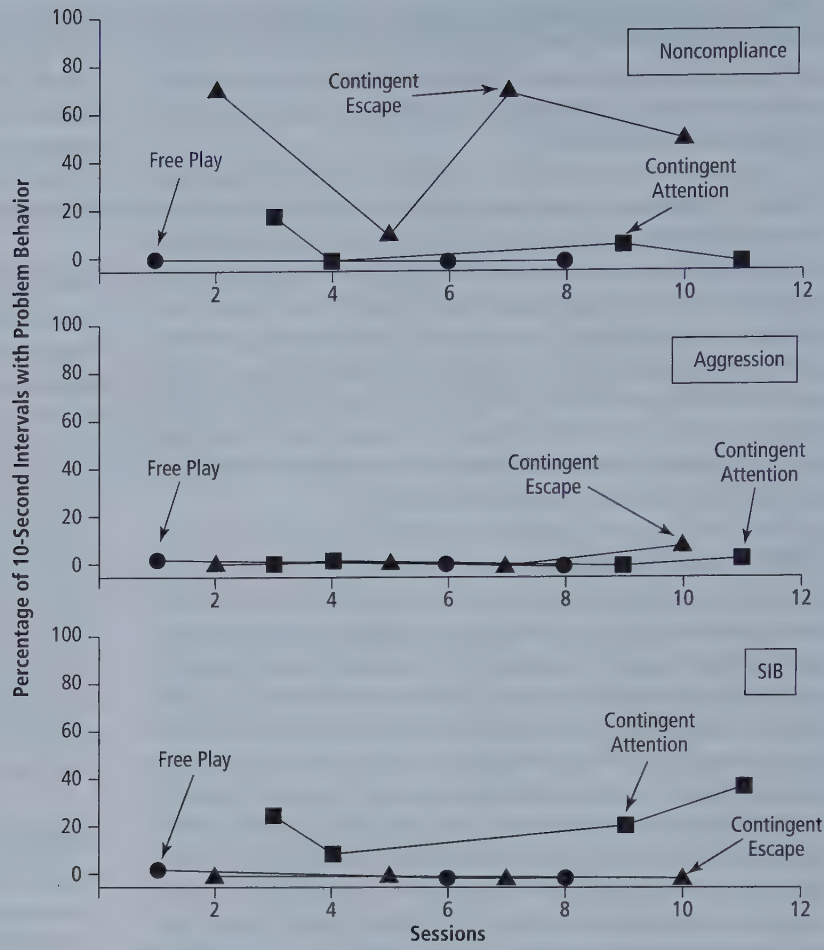

Figure 27.11 Results of Lorraine's functional analysis.

Based on Lorraine's functional analysis conducted by Corrine M. Murphy and Tabitha Kirby.

SUMMARY

Functions of Behavior

1. Many problem behaviors are learned and maintained by positive, negative, and/or automatic reinforcement. In this respect, problem behavior can be said to have a "function" (e.g., to "get" something or to "get out of" something).

2. The *topography*, or form, of a behavior often reveals little useful information about the conditions that account for it. Identifying the *conditions* that account for a behavior (its function) suggests what conditions need to be altered to change the behavior. Assessment of the function of a behavior can therefore yield useful information with respect to intervention strategies that are likely to be effective.

Role of Functional Behavior Assessment in Intervention and Prevention

3. FBA can lead to effective interventions in at least three ways: (a) It can identify antecedent variables that can be altered to prevent problem behavior, (b) it can identify reinforcement contingencies that can be altered so that problem behavior no longer receives reinforcement, and (c) it can help identify reinforcers for alternative replacement behaviors.

4. FBA can decrease reliance on default technologies (increasingly intrusive, coercive, and punishment-based interventions) and contribute to more effective interventions. When FBAs are conducted, reinforcement-based interventions are more likely to be implemented than are interventions that include a punishment component.

Overview of FBA Methods

5. FBA methods can be classified into three types: (a) functional (experimental) analysis, (b) descriptive assessment, and (c) indirect assessment. The methods can be arranged on a continuum with respect to considerations such as ease of use and the type and precision of information they yield.

6. Functional analysis involves systematically manipulating environmental events thought to maintain problem behavior within an experimental design. The primary advantage of functional analysis is its ability to yield a clear demonstration of the variable or variables that relate to the occurrence of a problem behavior. However, this assessment method requires a certain amount of expertise to implement and interpret. Several variations of functional analysis procedures have been developed to adapt to a variety of situations and contexts, including brief functional analysis, conducting functional analyses in natural settings, trial-based functional analysis, synthesized functional analysis, latency-based functional analysis, and analyzing precursor behaviors.

7. Descriptive assessment involves observation of the problem behavior in relation to events that are not arranged in a systematic manner and includes ABC recording (both continuous and narrative) and scatterplot recording. The primary advantages to these assessment methodologies are that they are easier to do than functional analyses and they represent contingencies that occur within the individual's natural routine. Caution must be exercised when interpreting information from descriptive assessments, however, because it can be very difficult to parse the contingencies via them.

8. Indirect functional assessment methods use structured interviews, checklists, rating scales, or questionnaires to obtain information from persons who are familiar with the individual exhibiting the problem behavior (e.g., teachers, parents, caregivers, and/or the individual himself or herself) to identify possible conditions or events in the natural environment that correlate with the problem behavior. Again, these forms of FBA are easy to conduct, but they are limited in their accuracy. As such, they are probably best reserved for hypothesis formulation. Further assessment of these hypotheses is almost always necessary.

Conducting a Functional Behavior Assessment

9. Given the strengths and limitations of the different FBA procedures, FBA can best be viewed as a four-step process:
   - First, gather information via indirect and descriptive assessment.
   - Second, interpret information from indirect and descriptive assessment and formulate hypotheses about the purpose of problem behavior.
   - Third, test hypotheses using functional analysis.
   - Fourth, develop intervention options based on the function of problem behavior.

10. When teaching an alternative behavior as a replacement for problem behavior, the replacement behavior should be functionally equivalent to the problem behavior (i.e., the replacement behavior should produce the same reinforcers that previously maintained the problem behavior).

KEY TERMS

conditional probability
contingency reversal

functional analysis
functional behavior assessment (FBA)
functionally equivalent
indirect functional assessment

MULTIPLE-CHOICE QUESTIONS

1. Devonia hits her head with a closed fist when her one-on-one teaching assistant leaves her side to interact with another student. Usually, when Devonia does this, her teaching assistant returns to her side, asks her to stop hitting herself, and soothes her. She rarely engages in head hitting when her assistant works directly with her. What is the most likely function of Devonia's problem behavior?
   a. Escape
   b. Attention
   c. Automatic reinforcement
   d. Tangible
   e. Escape and/or tangible
   Hint: (See "Functions of Behavior")

2. Charles spits on his teacher when he prompts him to complete a toothbrushing task. For obvious reasons, this behavior really grosses out the teacher, who refuses to work with him when he behaves like this. When Charles spits on him, the teacher walks away and allows Charles to leave the toothbrushing task and go to the computer to calm down. As long as he is playing on the computer, he rarely spits on his teacher. What is the most likely function of Charles' behavior?
   a. Escape
   b. Automatic reinforcement
   c. Tangible
   d. Escape and/or tangible
   e. Escape and/or attention
   Hint: (See "Functions of Behavior.")

3. On a practical level, FBA is important for prevention of and intervention for problem behavior because:
   a. When the cause-and-effect relation between environmental effects and behavior can be determined, that relation can be altered to improve behavior.
   b. It meets the federal guidelines for best practices in treating problem behavior.
   c. It will tell a teacher exactly what to do for intervention.
   d. None of these
   Hint: (See "Role of Functional Behavior Assessment in Intervention and Prevention")

4. Devonia's one-on-one assistant (see Question 1) decides that he will no longer leave Devonia's side to interact with other children as an intervention for her problem behavior. This is an example of what form of intervention?
   a. Altering antecedent variables
   b. Altering consequent variables
   c. Teaching alternative behaviors
   d. All of these

   Hint: (See "Role of Functional Behavior Assessment in Intervention and Prevention")

5. There are at least three forms of FBA. They are:
   a. Functional analysis, standardized assessment, and descriptive assessment
   b. Indirect assessment, descriptive assessment, and behavioral observation
   c. Functional analysis, descriptive assessment, and indirect assessment
   d. Behavioral observation, standardized assessment, and curriculum-based assessment

   Hint: (See "Overview of FBA Methods")

6. Which methods of FBA allow you to confirm hypotheses regarding the function of problem behavior?
   a. Functional analysis
   b. Descriptive assessment
   c. Indirect assessment
   d. All of these

   Hint: (See "Overview of FBA Methods")

7. Which of the following describes a descriptive functional behavior assessment?
   a. An analog analysis in which consequences representing those in the natural routine are systematically arranged.
   b. Direct observation of behavior made under naturally occurring conditions
   c. Structured checklists that caregivers fill out to identify events that correlate with problem behavior
   d. Behavior rating scales that caregivers fill out to identify events that correlate with problem behavior

   Hint: (See "Descriptive Functional Behavior Assessment")

8. A limitation of descriptive assessment is:
   a. It may be misleading in that it can identify environmental variables that occur in close proximity to the problem behavior but that are not causally related to the problem behavior.
   b. It may not be a very reliable measure of problem behavior and environmental events.
   c. It is extremely difficult and time-consuming to perform.
   d. The first two answer choices are correct.

   Hint: (See "Descriptive Functional Behavior Assessment")

9. Ms. Frieder, who teaches fifth grade at Franklin Elementary School, decides to conduct a descriptive FBA for Amelia. Amelia has been refusing to do her schoolwork lately and has been ripping up her worksheets on a daily basis. Ms. Frieder creates a form on which she will mark specific antecedents and consequences that precede and follow Amelia's work refusals. For antecedents, she will mark one of the following: Math work given, reading work given, spelling work given, error correction given, work that requires writing given. For consequences, she will mark one of the following: verbal reprimand, another worksheet (same worksheet) provided, another worksheet (different worksheet) provided, time out, ignore. She will record these environmental events, whether or not a problem behavior occurs. What kind of descriptive assessment is Ms. Frieder conducting?
   a. Scatterplot recording
   b. ABC continuous recording
   c. ABC narrative recording
   d. Conditional probability recording

   Hint: (See "Descriptive Functional Behavior Assessment")

10. Mr. Peterson has been struggling with Arnold, a boy with severe disabilities who hums and rocks back and forth intermittently throughout the day. Mr. Peterson wants to see if these behaviors are associated with any specific activities during the school day so that he can then more closely analyze what occurs during those time periods. Which descriptive assessment method would be the best choice for what he wants to accomplish?
    a. Scatterplot recording
    b. ABC continuous recording
    c. ABC narrative recording
    d. Functional analysis

    Hint: (See "Descriptive Functional Behavior Assessment")

11. Ms. Carmichael is conducting an FBA for Jamal, a boy in her class who runs away from activities and teachers. Ms. Carmichael began by interviewing her teaching assistants and by participating in the conversation with them to define the target behavior and to determine what antecedents and consequences she would watch for during her ABC assessment. Ms. Carmichael completes her ABC assessment and finds that running away from tasks and materials occurs most frequently when difficult tasks are presented and that the most common consequence for this behavior is a teacher chasing after him and returning him to the classroom. Sometimes he is required to return to the task and sometimes he is allowed to do a different activity when he comes back to the classroom. What can be concluded from this descriptive assessment?
    a. The problem behavior most likely occurs to get attention from teachers
    b. The problem behavior most likely occurs to escape from nonpreferred tasks.
    c. The problem behavior most likely occurs to get access to more preferred activities.
    d. The function of the problem behavior remains unclear.

    Hint: (See "Conducting a Functional Behavior Assessment")

12. After you complete a descriptive assessment, you should write hypothesis statements that reflect your interpretation of the data. Which of the following is a hypothesis statement that contains all of the important elements?
   a. Gain peer attention: When Valerie is playing alone on the playground, she bear hugs her peers.
   b. Gain peer attention: Valerie bear hugs her peers, which is followed by attention in the form of teasing from her peers.
   c. When Valerie is playing alone on the playground, she bear hugs her peers, which is followed by attention in the form of teasing from her peers.
   d. Gain peer attention: When Valerie is playing alone on the playground, she bear hugs her peers, which is followed by attention in the form of teasing from her peers.

   Hint: (See "Conducting a Functional Behavior Assessment")

13. The primary reason for conducting a functional analysis is:
   a. To test hypotheses generated via indirect and descriptive assessments.
   b. To generate hypotheses that can be further evaluated via indirect and descriptive assessments.
   c. To observe problem behavior within the naturally occurring routine.
   d. To identify any temporal patterns in problem behavior.

   Hint: (See "Overview of FBA Methods")

14. Characteristics of functional analysis include:
   a. They are conducted within naturally occurring routines.
   b. They are conducted within analog conditions that represent naturally occurring routines.
   c. They utilize interviews and rating scales rather than direct observation of problem behavior.
   d. They are conducted in clinical settings only.

   Hint: (See "Functional (Experimental) Analysis")

15. In addition to a control condition, a functional analysis typically consists of what test conditions?
   a. Contingent attention
   b. Contingent escape
   c. Alone
   d. All of these

   Hint: (See "Functional (Experimental) Analysis")

16. Mr. Moon is conducting a functional analysis with Ira, who kicks his teachers frequently. Mr. Moon is implementing a contingent escape condition. He prompts Ira to engage in a difficult task. Ira kicks Mr. Moon in the shin. How should Mr. Moon respond if he is to implement the contingent escape condition correctly?
   a. He should continue prompting Ira to do the task, but he should provide a mild reprimand, such as, "Ira, don't kick me. That hurts. Come on, it's time to work."
   b. He should remove the task materials and turn away from Ira for a short period of time.
   c. He should ignore Ira's kicking and continue with the task.
   d. He should provide Ira with a more preferred activity for a short period of time.

   Hint: (See "Table 27.1, page 682")

17. Look at the following graph from a functional analysis of Elsa's tantrums. What would you conclude is the function of Elsa's tantrums?

   a. Escape
   b. Attention
   c. Both escape and attention
   d. The pattern of behavior is undifferentiated; therefore the analysis is inconclusive.

   Hint: (See "Overview of FBA Methods")

18. Look at the following graph from a functional analysis of Walter's skin picking. What would you conclude is the function of Walter's skin picking?

   a. Escape
   b. Attention
   c. Automatic
   d. The pattern of behavior is undifferentiated; therefore the analysis is inconclusive.

   Hint: (See "Overview of FBA Methods")

ESSAY-TYPE QUESTIONS

1. Provide an example of a problem behavior that is maintained by social positive reinforcement, social negative reinforcement, and automatic reinforcement. In your answer, state what happens prior to the problem behavior, what the problem behavior is, and what follows the problem behavior.

   Hint: (See "Functions of Behavior")

2. Discuss three different ways in which the results of a functional behavior assessment can be used to formulate interventions that prevent future occurrences of problem behavior.

   Hint: (See "Role of Functional Behavior Assessment in Intervention and Prevention")

3. Explain the three types of functional behavior assessment. Discuss them in the order in which they might best be implemented and explain this sequence. Your explanation of the sequence should include the strengths and limitations of each type.

   Hint: (See "Overview of FBA Methods and Case Examples")

4. Compare and contrast descriptive and indirect assessments. What is the primary variable that sets these two forms of gathering descriptive information apart?

   Hint: (See "Overview of FBA Methods: Descriptive Functional Behavior Assessment and Indirect Functional Behavior Assessment")

5. Give an example of a descriptive assessment and state what specific information this assessment would yield.

   Hint: (See "Overview of FBA Methods: Descriptive Functional Behavior Assessment")

6. Assume you are a behavioral consultant for a local developmental disabilities agency. You have been asked to consult on young adult, Melissa, who is 22 years old and frequently disrobes while at work. You conduct indirect and descriptive assessments with her staff and learn the following: Melissa rarely disrobes when she is in the break room having a snack and interacting with her co-workers and staff. She disrobes most frequently when she is working on her assigned job task. It doesn't seem to matter what task she is working on. You conduct an ABC assessment and note that she works well when a staff member comes by to check her work, and this seems to continue for a few minutes after the staff member leaves. About 4 minutes after the staff member leaves, however, the clothes start coming off. Melissa is happy to put her clothes back on when directed to by a staff member. Because of these behaviors, Melissa's work station has been moved to behind a curtain in the work room. Much to the staff's chagrin, Melissa's disrobing has actually been worsening since they did this. What is your working hypothesis for Melissa's problem behavior? Write your hypothesis in the form recommended by the text, and provide a rationale for your hypothesis.

   Hint: (See "Conducting a Functional Behavior Assessment: Gathering Information and Interpreting Information and Forming Hypotheses")

7. Explain the difference between a functional analysis and other forms of functional behavior assessment (e.g., descriptive and indirect assessments). Specifically, why is it that a functional analysis allows you to test hypotheses, while other forms of functional behavior assessment are used for hypothesis formulation?

   Hint: (See "Overview of FBA Methods: Basic Procedure")

8. Describe the conditions that might be implemented in a functional analysis, as well as how and why each condition is implemented.

   Hint: (See "Overview of FBA Methods: Basic Procedure" and "Conducting a Functional Behavior Assessment: Testing Hypotheses")

9. Assume that in your role as a consultant, you decide to conduct a functional analysis of Melissa's disrobing (see Question 6). Assume that your functional analysis indicates her disrobing is maintained by both attention from others and escape from task demands. Assume that the functional analysis also confirmed your hypothesis that she rarely engages in problem behavior when she has attention and no task demands. Draw a graph that would illustrate this function appropriately.

   Hint: (See "Case Examples Illustrating the FBA Process")

PART 11

Special Applications

Parts 4 through 10 described basic principles of behavior and behavior change tactics derived from those principles. Part 11 describes several applications of behavior change technology. Each application represents a strategic approach to change behavior using multiple principles and procedures. Chapter 28 addresses the token economy, group contingencies, and contingency contracting. Chapter 29 details tactics individuals can implement to change their own behavior.

CHAPTER 28

Token Economy, Group Contingencies, and Contingency Contracting

LEARNING OBJECTIVES

- Define and identify the components of a contingency contract.
- Define and identify the components of a token economy.
- Explain the considerations that must be made when implementing a token economy.
- Define and identify the different types of group contingencies.
- Explain the considerations that must be made when implementing a group contingency.

This chapter addresses the token economy, group contingencies, and contingency contracting as behavior change strategies. Each strategy will be defined and its relationship to behavioral principles explained; requisite components of each strategy will be addressed and guidelines for designing, implementing, and evaluating each will be presented. These three strategies are grouped because they have several features in common. A well-established research base supports their effectiveness. Further, they can be combined with other approaches in package programs to provide an additive effect. Also, each strategy can be used with individual and multiple group arrangements. Finally, the flexibility of these three special applications makes them attractive options for practitioners in various settings.

TOKEN ECONOMY

The token economy is a highly developed and broadly researched behavior change system. It has been applied successfully in virtually every educational, residential, employment, and therapeutic setting possible (Bullock & Hackenberg, 2006; Doll, McLaughlin, & Barretto, 2013; Glynn, 1990; Hackenberg, 2009; Musser, Bray, Kehle, & Jenson, 2001; Pietras & Hackenberg, 2005; Stilitz, 2009; Wolfe, 1936). The utility of a token economy to change behaviors that previously have been resistant to modification is well established in the experimental and applied literatures. Further, token economies have proved successful whether administered by practitioners (Jowett Hirst, Dozier, & Payne, 2016) or even peer groups of children in elementary schools (Alstot, 2015). This section defines and describes the token economy and outlines effective procedures for using it in applied settings.

Token Economy Defined

A **token economy** (or *token reinforcement* system) consists of three major components: (a) a list of target behaviors; (b) tokens, points, or marks participants earn for emitting the target behaviors; and (c) a menu of **backup reinforcers**—preferred items, activities, or privileges—that participants obtain by exchanging earned tokens. Hackenberg (2009) described a token economy as "an interconnected set of contingencies that specifies the relations between token production, accumulation, and exchange" (p. 259). Operationally, these interconnections work in three stages. First, the behavior or behaviors to be reinforced are identified and defined. Second, a medium of exchange—the **token**—is selected. Third, participants exchange earned tokens for backup reinforcers (i.e., objects, privileges, or activities known or presumed to function as reinforcers for participants).

> In addition to having three stages, A token economy derives its complexity from the three interconnected schedules of reinforcement that govern when tokens will be delivered (token production), when tokens will be exchanged (exchange production), and the cost in tokens of the various goods or services available for exchange (token exchange; Hackenberg, 2009). These schedules of reinforcement represent internal mechanisms of a token economy that can be arranged using a number of basic reinforcement schedules (e.g., fixed ratio and variable interval) or complex schedules (e.g., differential reinforcement of other behavior). (Ivy, Meindl, Overley, & Robson, 2017, p. 3)

The Functions of Tokens

Store-based or manufacturer coupons function as tokens. When a customer purchases an item from a participating store, the cashier provides the purchaser with a paper coupon directly or electronically through a smartphone or tablet device. That coupon is traded later for another item at a reduced price, or it is redeemed immediately for the backup conditioned reinforcer.

Money, in the form of currency, is an example of a token that can be exchanged at a later time for backup objects and

activities (e.g., food, clothing, transportation, entertainment). As Bell and McDevitt (2014) stated:

> To see the enormous power of conditioned reinforcement, one must only consider the potent effects of money on human behavior. A "token" is an object that can be exchanged for other reinforcers. It is also called a "generalized reinforcer," as it does not need to rely on a single reinforcer in order to be effective. Money is one such token and maintains much of our behavior, but other kinds of tokens can be used to establish or maintain specific behaviors. (p. 242)

Hackenberg (2009) noted that, "A token, as the name implies, is an object of no intrinsic value; whatever function(s) a token has is established through relations to other reinforcers, both unconditioned (e.g., food or water) or conditioned (e.g., money or credit). As such, a token may serve multiple functions—reinforcing, punishing, discriminative, eliciting—depending on its relationship to these other events" (p. 259).

The multiple functions of tokens figure importantly in a token economy, which is often effective in applied settings, for three reasons. First, tokens bridge the time gap between the occurrence of a behavior and delivery of a backup reinforcer. For example, a token may be earned during the afternoon, but the backup reinforcer is not awarded until the next morning. Second, tokens bridge the setting gap between the behavior and the delivery of the backup reinforcer. For instance, tokens earned at school could be exchanged for reinforcers at home, or tokens earned in a general education classroom in the morning could be exchanged in a special education classroom in the afternoon. Finally, as generalized conditioned reinforcers, tokens make the management of motivation less critical for the behavior analyst.

Tokens are generalized conditioned reinforcers, and as such are independent of specific states of motivation because they are associated with a wide array of backup reinforcers. However, a generalized conditioned reinforcer is a relative concept: Effectiveness depends to a large extent on the extensiveness of the backup reinforcers and their ability to affect the future occurrence of behaviors (Moher, Gould, Hegg, & Mahoney, 2008). Tokens exchangeable for a wide variety of backup reinforcers have considerable utility in schools, clinics, centers, and hospitals where it is difficult to manage the delivery of powerful reinforcers, or deprivation states, which may change with time or location.

Higgins, Williams, and McLaughlin (2001), for example, used a token economy to decrease the disruptive behaviors of an elementary-age student with learning disabilities. The student exhibited high levels of out-of-seat, talking out, and poor sitting behaviors. After collecting baseline data on these behaviors, a token economy was implemented. If an alternative behavior was being emitted instead of the behaviors targeted for reduction, the student earned a checkmark exchangeable for free time. Maintenance checks were taken on two subsequent occasions to determine duration effects.

Figure 28.1 displays the results of the study across the three dependent variables. A functional relation was established between the onset of the token economy and the reduction of the behaviors. Further, maintenance checks indicated that the behavior remained at low levels after the token economy phase ended.

Level Systems

A **level system** is a type of token economy in which participants move up (and sometimes down) a hierarchy of tiers contingent on meeting specific performance criteria with respect to the target behaviors. As participants move "up" from one level to the next, they have access to more privileges and are expected to demonstrate more independence (see example in Table 28.1). The schedule of token reinforcement is gradually thinned so that participants at the highest levels are functioning on schedules of reinforcement similar to those in natural settings.

According to Smith and Farrell (1993), level systems are an outgrowth of two major educational advances that began in the late 1960s and 1970s: (a) Hewett's *Engineered Classroom* (1968) and (b) Phillips, Phillips, Fixen, and Wolf's *Achievement Place* (1971). In both cases, systematic academic and social programming combined token reinforcement, tutoring systems, student self-regulation, and managerial arrangements. Smith and Farrell stated that level systems are designed to

> foster a student's improvement through self-management, to develop personal responsibility for social, emotional, and academic performance . . . and to provide student transition to a less restrictive mainstream setting. . . . Students advance through the various levels as they show evidence of their achievement. (p. 252)

In a level system, students must acquire and achieve increasingly more refined repertoires while tokens, social praise, or other reinforcers are simultaneously decreased. Level systems have built-in mechanisms for participants to advance through a series of privileges, and they are based on at least three assumptions: (a) Combined techniques—so-called "package programs"—are more effective than individual contingencies introduced alone, (b) student behaviors and expectations must be stated explicitly, and (c) differential reinforcement is necessary to reinforce closer and closer approximations to the next level (Smith & Farrell, 1993).

Lyon and Lagarde (1997) proposed a three-level group of reinforcers that placed useful, but less desirable, reinforcers at Level 1. At this level, students had to earn 148 points, or 80%, of the 185 maximum points that could be earned during the week to purchase certain items. At Level 3, the powerful, and highly desirable, reinforcers could be purchased only if the students had accumulated at least 167 points, or 90%, of the total points possible. As the levels progress, the expectations for performance increase.

Cavalier, Ferretti, and Hodges (1997) incorporated a self-management approach with an existing level system to improve the academic and social behavior of two adolescent students with learning disabilities for whom increased participation in a general education classroom was an individualized education program (IEP) goal. Basically, other students in the classroom were making adequate progress through the six-level point system that the teacher had devised, but the inappropriate

verbalizations of the two target students during class stalled their progress at Level 1. After collecting baseline data on the number of inappropriate verbalizations, the researchers trained the students to self-record occurrences of these behaviors during two 50-min intervals in the day. Inappropriate verbalizations were defined explicitly, and during mock trials the students practiced self-recording and received feedback based on teacher observations during the same interval. An emphasis was placed on the accuracy of the students' recording, and desirable reinforcers were awarded for accurate recording. During the intervention (level system plus self-recording), students were told that they would be observed during the two 50-min intervals for accuracy. If they met the criterion for each level (e.g., a decrease of five inappropriate verbalizations from the previous session), a reinforcer was delivered. As the students progressed through the levels, the reinforcer changed to more highly desirable items.

Results showed a high number of verbalizations during baseline; however, when the packaged intervention was initiated for Student 1, inappropriate verbalizations decreased. This outcome was replicated for Student 2, confirming a functional relation between the intervention and the decrease in inappropriate verbalizations.

Designing a Token Economy

The basic steps in designing and preparing to implement a token economy are as follows:

1. Identify target behaviors and rules.
2. Select tokens.
3. Develop a menu of backup reinforcers.
4. Establish a token exchange ratio.
5. Determine when and how tokens will be dispensed and exchanged and what will happen if the requirements to earn a token are not met.
6. Field-test the system before full-scale implementation.

Identify Target Behaviors and Rules

Chapter 3 addressed the selection and definition of behavior change targets. The criteria presented in that chapter also apply to the selection and definition of rules and target behaviors for a token economy. Generally, the guidelines for selecting behaviors for a token economy include: (a) selecting only measurable and observable behaviors; (b) specifying criteria for successful task completion; (c) starting with a small number of behaviors, including some that are easy for the individual to accomplish; and (d) being sure the participants have the prerequisite skills for any targeted behaviors (Myles, Moran, Ormsbee, & Downing, 1992).

After rules and behaviors that apply to everyone are defined, then criteria and behaviors specific to individual learners should be established. Many token economy failures can be traced to requiring the same behaviors and setting the same criteria for all learners. Token economies usually need to be individualized. For example, in a classroom setting, the teacher may want to select different behaviors for each student, or perhaps the token economy should not be applied to all students in the classroom. Instead, only the students with the greatest challenges should be included. However, students who do not need a token system should still continue to receive other forms of reinforcement.

Select Tokens

Frequently used tokens include points, tally marks, plastic strips, checkers, coupons, poker chips, holes punched in a card, or teacher initials. Criteria to consider in selecting the token itself are important. First, tokens should be safe. If a young child or participant with severe learning or behavioral problems is to receive the token, it should not be an item that can be swallowed or otherwise used to cause injury. Also, tokens should not be large, cumbersome, or unwieldy. Second, the analyst should control token physical configuration; learners should not be able to bootleg the acquisition of tokens by surreptitiously manufacturing their own. If tally marks are used, they should be on a special card, or made with a special marking pen that is available only to the analyst. Likewise, if holes are punched in a card, the paper punch should be available only to the analyst to avoid counterfeiting.

Tokens should be durable because they may have to be used for an extended period, and they should be easy to carry, handle, bank, store, or accumulate. Tokens should also be readily accessible to the practitioner at the moment they are to be dispensed. It is important that they be provided immediately after the target behavior. Tokens should be inexpensive; there is no need to spend a large sum of money to purchase tokens. Injectable stamps, stars, checkmarks, and buttons are all inexpensive items that can be used repeatedly as tokens.

Although using desirable objects as tokens can backfire—a teacher who used baseball cards as tokens found students spent so much time interacting with the tokens (e.g., reading about players) that the tokens distracted students from the purpose of the system—for some students, the "objects of obsession" can serve as effective tokens. In a study by Charlop-Christy and Haymes (1998), three children with autism who attended an after-school program served as participants. All three children were consistently off task during activities, preoccupied with some objects, and engaged in self-stimulatory behaviors. During baseline, the students earned stars for appropriate behavior.

Inappropriate behaviors or incorrect responses were addressed by saying, "try again" or "no." When the students earned five stars, the tokens could be exchanged for backup reinforcers (e.g., food, pencils, tablets). During the token condition, an "obsession" object (one the children had been previously preoccupied with) was used as the token. Once they had earned five obsession objects, children could exchange them for food items or other known reinforcers. Charlop-Christy and Haymes reported that the overall pattern of responding demonstrated that when the token was an obsession object, student performance improved.

Develop a Menu of Backup Reinforcers

Most token economies can use naturally occurring activities and events as backup reinforcers. For example, in a classroom, center, or school setting, tokens can be exchanged for popular games or materials, or they can be traded for favorite classroom jobs, such as office messenger, materials distributor, teacher assistant, or media operator. Tokens can also be used for schoolwide privileges, such as a library or study hall pass; a special period (e.g., music, physical education) with another class; or special responsibilities, such as school patrol, cafeteria monitor, or tutor. Higgins and colleagues (2001) used naturally occurring activities and events as backup reinforcers for their token economy (i.e., the students had access to computer games and leisure books). However, play materials, hobby-type games, snacks, television time, allowance, permission to go home or downtown, sports events, and coupons for gifts or special clothing could also be used as backup reinforcers because these objects or items tend to occur in many settings.

If naturally occurring routine activities and events have not served as reinforcers in the past, then conducting a reinforcer assessment would be advisable (Sran & Borrero, 2010). Identifying backup reinforcers using a formal assessment procedure increases the chances that those stimulus items will serve as reinforcers. Further, an assessment would identify known reinforcers specific to the individual, and not suspected generic reinforcers for the group. Depending on the population of students to be served, analysts should be prepared to conduct multiple assessments over time as reinforcer preference can shift and change (DeLeon et al., 2001). All practitioners should use the most powerful, but least intrusive, and naturally occurring reinforcers possible.

Finally, selection of backup reinforcers should follow consideration of ethical and legal issues, as well as state and local education agency policies. Token reinforcement contingencies that would deny the learner basic needs (e.g., food) or access to personal or privileged information or events (e.g., access to mail, telephone privileges, attending religious services, medical care, scheduled recess) should not be used. Furthermore, general comforts that are associated with basic rights afforded to all citizens (e.g., clean clothing, adequate heating, ventilation, hot water) should not be used in a token program.

Establish a Token Exchange Ratio

Initially, the ratio between the number of tokens earned and the price of backup items should be small to provide immediate success for learners. Thereafter, the ratio of exchange should be adjusted to maintain the responsiveness of the participants. Following are general guidelines for establishing the ratio between earned tokens and the price of backup items:

- Keep initial ratios low.
- As token-earning behaviors and income increase, increase the cost of backup items, devalue tokens, and increase the number of backup items.
- With increased earnings, increase the number of luxury backup items.
- Increase the prices of necessary backup items more than those of luxury items.

Determine How the Tokens Will Be Dispensed

If objects such as tally marks or holes punched in a card are selected as the tokens, how the learner will receive them is obvious. If objects such as coupons or poker chips are used, some container should be made available for storing the accumulated tokens before they are exchanged for the backup items. Some practitioners have learners construct individual folders or containers for storing their tokens. Another suggestion is to deposit the tokens through cut slots in the plastic tops of coffee cans. With younger learners, tokens can be chained to form a necklace or bracelet.

Determine How the Tokens Will Be Exchanged

A menu of the backup items should be provided with a given cost for each item. Learners can then select from the menu. Some teachers have a table store with all the items displayed (e.g., games, balloons, toys, certificates for privileges). To avoid noise and confusion at shopping time, individual orders can be filled by writing in or checking off the items to be purchased. Those items are then placed in a bag with the order form stapled to the top and are returned to the purchaser. Initially, the store should be open frequently, perhaps twice per day. Lower functioning learners may need more frequent exchange periods. Later, exchange periods might be available only on Wednesdays and Fridays, or only on Fridays. As quickly as possible, token exchange should occur on an intermittent basis.

Specify What Happens if Token Requirements Are Not Met

Occasionally, token requirements will not be met for one reason or another. One approach is to nag the individual: "You didn't do your homework. You know your homework must be completed to earn tokens. Why didn't you do it?" A better approach is a matter-of-fact restatement of the contingency: "I'm sorry. You haven't enough tokens to exchange at this time. Try again." It is important to know whether the individual has the skills required to earn tokens. A learner should always be able to meet the response requirements.

What Should Be Done When a Learner Tests the System? How should a practitioner respond when a learner says she does not want any tokens or backup items? A bad approach would be to argue, debate, or cajole the learner. A better approach is to

say something neutral (e.g., "That is your decision.") and then walk away, precluding any argument or debate. In this way a confrontation is avoided, and the occasion remains set for token delivery for the learner. Most learners can and should have input in selecting the backup items, generating the rules for the economy, establishing the price for the backup items, and performing general duties in managing the system. A learner can be a salesperson for the store or a bookkeeper to record who has how many tokens and what items are purchased. When learners are involved and their responsibilities for the economy are emphasized, they are less likely to test the system.

Will the Token Economy Include a Response Cost Contingency? Procedures for including response cost—a negative punishment procedure—with a token economy were presented in Chapter 15. Token economies can include a token loss contingency for inappropriate behaviors and rule infractions (Musser et al., 2001). Any behaviors subject to response cost should be defined and stated clearly in the rules. Learners need to be aware of what actions will result in token loss and how much the behavior will cost. The more serious the inappropriate behavior is, the greater the token loss should be. Clearly, fighting, acting out, or cheating should result in greater token loss than minor infractions (e.g., out-of-seat behavior or talk-outs). Token loss should never be applied to a behavior if the learner does not have tokens. Students should not be allowed to go into debt, which would likely decrease the reinforcement value of the tokens. A learner should always earn more tokens than she loses.

Several studies have compared the effectiveness of token-loss (response cost) or token-earn contingencies. In response cost procedures, each participant starts with a number of tokens and loses a token on each instance of the problem behavior (e.g., Conyers et al., 2004; Donaldson, DeLeon, Fisher, & Kahng, 2014; McGoey & DuPaul, 2000). With a token-earn procedure, children earn tokens contingent on emitting specified desired behaviors or for the absence of problem behavior during specified intervals (DRO). Jowett Hirst et al. (2016) compared the effects of token-earn and token-loss contingencies on the on-task performance of students working in individual and group contexts. Results showed that both contingencies were effective in increasing on-task behavior (see Figure 8.17). When given a choice of which contingency would operate during each session, five of six children chose the response cost over the token earn.

Because the token-loss contingency required less time to implement, teachers who use a token system as a behavior management strategy might find arranging loss contingencies to be a better option than arranging earn contingencies. Box 28.1: "Coupons for Cursing," describes how a teacher incorporated response cost procedure into a classwide token economy.

Field-Test the System

The final step before actually implementing a token system is to field-test it. For 3 to 5 days, token delivery is tallied exactly as if tokens were being earned, but no tokens are awarded during the field test. Data from the field test are used for assessment. Are learners actually deficient in the targeted skills? Are some learners demonstrating mastery of behaviors targeted for intervention? Are some learners not receiving tokens? Based on answers to questions such as these, final adjustments in the system can be made. For some learners, more difficult behaviors may need to be defined; others may need less demanding target behaviors. Perhaps more or fewer tokens need to be delivered relative to the price of the backup reinforcers.

BOX 28.1

Coupons for Cursing

During my second year as a middle school teacher for students with learning disabilities and behavior disorders, I was plagued with a number of students for whom refraining from blurting out curse words and expletives was nearly impossible. At the first sign of frustration with a seatwork assignment or a negative encounter with a classmate, the expletives would roll out of their mouths like an "Old Faithful" gusher. Such outbursts were contagious and extremely problematic.

To address this issue, after collecting baseline data on the number of curses per morning, I devised a program that provided each target student with a stapled pack of 10 index cards on which I had written: **Coupon: Good for One Free Curse. Turn in After Cursing**.

I told the students in individual meetings with each of them that since our morning workload kept me busy, I would not have time to personally redirect them when they cursed. Instead, I told them that when I heard them curse, I would look at them and give them a personal signal (i.e., a tug on my ear, a tap to my nose, a touch to my shoulder, etc.). Tugs, taps, and touches were specific to each student. When the student saw that signal, he was to tear off the top coupon from the pack of 10 and put it on my desk. Also, he was told that all remaining coupons could be added to the pool of points that he otherwise would earn for completing academic work. In effect, the remaining coupons became "bonus tokens" exchangeable for inexpensive, but desirable, items that were available on Friday at the "Classroom Store." The program quickly reduced the number of expletives emitted by the target students. In effect, they learned that the extra coupons provided the opportunity to buy more highly desirable items that they otherwise would not have been able to afford.
—Timothy E. Heron

Implementing a Token Economy

Training Staff

To launch a token economy successfully, practitioners must learn all implementation elements. The behavior analyst can assist in this process by developing checklists of key operational components and teaching these components systematically using a direct instruction "model-lead-test" (MLT) procedure. The MLT procedure emphasizes the behavior analyst's role in demonstrating, role playing with trainees, conducting supervised and independent practice, and providing feedback and reinforcement. Further, and more importantly, the behavior analyst must recognize that during initial training, the trainees are on a learning curve and will make mistakes. The behavior analyst should be prepared to conduct booster training, review sessions, or monitoring protocols to ensure that the token system is being implemented as designed when the trainee is on her own.

Plavnick, Ferreri, and Maupin (2010) found that two 1-hr training sessions on how to implement the steps of a token economy did not produce high levels of implementation by three teachers in an early childhood special education class. Prior to training sessions, teachers implemented virtually none of the key elements of the token program. During training, the number of token steps executed correctly increased substantially for all three teachers. However, during the implementation phase, when teachers were conducting the program alone, the number of steps decreased markedly. The data show that the teachers failed to execute the checklist items they "learned" during training. When self-monitoring was introduced, the number of checklist items completed accurately increased and remained high. Plavnick et al. remind practitioners that additional support and monitoring may be needed after initial training to maintain high levels of performance.

Initial Token Training

The manner in which initial training is conducted to launch a token economy depends on the functioning level of the learners. For high-functioning learners, or those children with mild disabilities, initial training might require minimal time and effort and consist primarily of verbal instructions or modeling. Usually the initial token training for these individuals can be accomplished in one 30- to 60-min session. Three steps are normally sufficient. First, an example of the system should be given. The practitioner might describe the system as follows:

> This is a token and you can earn it by [specify behavior]. I will watch your behavior; and when you [specify behavior], you will earn a token. Also, as you continue [specify behavior], you will earn more tokens. At [specify time period] you will be able to exchange the tokens you have earned for whatever you want and can afford on this table. Each item is marked with the number of tokens needed for purchase. You can spend only the tokens you have earned. If you want an item that requires more tokens than you have earned, you will have to save your tokens over several [specify time period].

The second step is to model the procedure for token delivery. For instance, each learner, or all group members, might be directed to emit the specified behavior. Immediately following the occurrence of the behavior, the learner(s) should be praised (e.g., "Enrique, I'm pleased to see how well you are working by yourself!") and the token delivered.

The third step is to model the procedure for token exchange. Learners should be taken to the store and shown the items for purchase. All learners should already have one token, which was acquired during the modeling of token delivery. At this time, several items should be able to be purchased for one token (the cost may go up later)—a game, 5 minutes of free time, a sticker or teacher helper privilege. Students should actually use their tokens in this exchange. Lower functioning learners may require several sessions of initial token training before the system is functional for them. Further response prompts may be needed.

Ongoing Token Training

During token reinforcement training, the practitioner and the students should follow the guidelines for effective use of reinforcement (see Chapter 11). For example, tokens should be dispensed contingently and immediately after the occurrence of the desired behavior. Procedures for delivery and exchange should be clear and should be followed consistently. If a booster session is needed to improve teacher, parent, or student performance of how tokens are dispensed, earned, or exchanged, practitioners should deliver it. Finally, the focus should be on building and increasing desirable behaviors through token delivery rather than decreasing undesirable behaviors through response cost.

Management Issues During Implementation

Students must be taught how to manage the tokens they earn. For instance, once received, tokens should be placed in a safe, but accessible, container so that they are out of the way, but readily available when needed. If the tokens are in clear view and easily accessible, some students might play with them at the expense of performing academic tasks assigned by the teacher. Also, placing the tokens in a secure location reduces the risk of other students counterfeiting or confiscating them. Preemptive measures should be taken to ensure that tokens are not easily fabricated or reachable by anyone other than the recipient. If counterfeiting or stealing occurs, switching to different tokens will help reduce the likelihood of these tokens being exchanged under false pretenses.

Another management issue, however, relates to students' token inventories. Some students may hoard their tokens and not exchange them for backup reinforcers. Other students may try to exchange their tokens for a backup reinforcer, but they lack the requisite number of tokens to do so. Both extremes should be discouraged. That is, the program expectation should be that all students exchange at least some of their earned tokens periodically. Obviously, students without the requisite number of tokens should not be permitted to "borrow" against future projected earnings so as to participate in an exchange. Stated otherwise, they should not be permitted to buy backup reinforcers on credit.

A final management issue relates to chronic rule breakers, saboteurs, or students who test the system at every turn. Practitioners can minimize this situation by (a) ensuring that the tokens function as a generalized conditioned reinforcers, (b) conducting a reinforcer assessment to determine that the

backup items function as reinforcers and are preferred by each of the students, and (c) applying alternative procedures for chronic rule breakers. Specifically, if an individual student tries to sabotage the system, that student's program might be modified so that tokens are combined with a differential reinforcement of alternative behavior procedure, extinction, or brief time-out.

Withdrawing a Token Economy

Practitioners may be so encouraged by the effectiveness of the token economy they have worked so hard to design and implement that they do not want to remove the system. However, in most cases, practitioners and analysts should consider how they will gradually scale down, and ultimately remove, the program. One goal of the token program should be to have the descriptive verbal praise that is delivered simultaneously with the token acquire the reinforcing capability of the token. From the beginning, a systematic aim of the token economy should be to withdraw the program. Such an approach, aside from having functional utility for practitioners (i.e., they will not have to issue tokens forever), also has advantages for the learner. For example, if a special education teacher is using a token economy with a student scheduled for full-time placement in a regular fourth-grade classroom, the teacher wants to be certain that the student's responses can be maintained in the absence of the token economy.

Various methods have been used to withdraw token reinforcers gradually after criterion levels of behavior have been reached. The following six guidelines allow the practitioner to develop, and later withdraw, token reinforcers effectively.

First, the token presentation should always be paired with social approval and verbal praise. This should increase the reinforcing effect of the social approval and serve to maintain behaviors after token withdrawal.

Second, the number of responses required to earn a token should be gradually increased. For instance, if a student receives a token initially after reading only one page, he should be required to read more pages later for token delivery.

Third, the duration the token economy is in effect should be gradually decreased. For example, during September the system might be in effect all day; in October, the time might be 8:30 AM to 12:00 PM and 2:00 PM to 3:00 PM; and in November, the time could be reduced to 8:30 AM to 10:00 AM and 2:00 PM to 3:00 PM. In December, the times might be the same as those in November, but on only 4 days a week, and so on.

Fourth, the number of activities and privileges that serve as backup items and are likely to be found in the untrained setting should be increased gradually. For example, the analyst should start taking away tangible items in the store that might not be present in the regular classroom. Are edibles available at the store? They are usually not available for reinforcement in regular classrooms. Gradually, items should be introduced that would be common in a regular class (e.g., special award sheets, gold stars, positive notes sent home).

Fifth, the price of more desirable items should be increased systematically while keeping a very low price on less desirable items for exchange. For example, in a token system with adolescent girls who have moderate to severe intellectual disabilities, the prices of candy bars and trips to the canteen and grooming aids (e.g., comb, deodorant) were initially about the same. Slowly, the cost of items such as candy bars was increased to such a high level that the girls no longer saved tokens to purchase them. More girls used their tokens to purchase grooming aids, which cost substantially less than candy.

Sixth, the physical evidence of the token should be faded over time. The following sequence illustrates how the physical evidence of the token can be faded.

- Learners earn physical tokens such as poker chips or washers.
- The physical tokens are replaced with slips of paper.
- The slips of paper are replaced with tally marks on an index card that is kept by the learners.
- In a school setting, the index card can now be taped to the learner's desk.
- The index card is removed from the learner and is kept by the analyst, but participants can check their balance at any time.
- The analyst keeps tallies, but no checking is allowed during the day. Totals are announced at the end of the day, and then every other day.
- The token system is no longer operative. The behavior analyst does not announce point totals even though they are still kept.

Evaluating a Token Economy

Token economies can be evaluated using any number of reliable, valid, field-tested, best-practice designs (e.g., reversal, multielement). Given that most token economy programs are conducted with small groups, single-subject evaluation designs allow for participants to serve as their own control. Applied behavior analysts should always strive to evaluate effectiveness at the individual level because despite aggregate group data demonstrating effectiveness, individual data may not be so robust (Davis & Chittum, 1994).

The Jowett Hirst et al. (2016) study described earlier is informative here. When group data were aggregated, both procedures were shown to be equally effective. However, when individual data served as the basis of comparison, many students performed better under the response cost contingency (see Figure 8.17). Had an individual analysis not been conducted, these results would have been masked by the overall group data. The authors concluded

> . . . the procedures were differentially effective for some individuals in the group, which suggests that analyzing individual data is important because these differences may not have been observed if we reported only group averages. The importance of analyzing individual data is further supported by the results of Study 2, which showed differential effects for three participants . . . , whereas the overall results suggest that the two procedures are equally effective. (pp. 340–341)

Collecting social validity data before, during, and/or after token economy with the target participants and the significant others helps to answer the question "Did the result(s) of token implementation make a difference for the participant(s)?" Jowett Hirst et al.'s (2016) post-study preference assessment showed

that the majority of students preferred the response cost condition, an interesting finding given the negative punishment protocol associated with this procedure. Importantly, such a finding gives at least slight pause to the generally recommended guidance to use "positive" approaches initially to effect behavior change, when evidence to the contrary shows that for some students, a negative punishment procedure may be effective and preferred.

Further Considerations

Its effectiveness notwithstanding, the token economy does present some challenges to learners and practitioners.

Intrusive. Token systems can be intrusive. It takes time, energy, and resources to establish, implement, and evaluate token programs. Also, because most natural environments do not reinforce a person's behavior with tokens, careful thought must be given to how to thin the token schedule while simultaneously maintaining performance. In any case, token economy programs can have lots of "moving parts," and practitioners must be prepared to deal with them.

Self-perpetuating. A token economy can be an effective procedure for managing behavior, and analysts can be so encouraged by the results that they do not want to remove the system. Learners then continue working for backup reinforcers that may not normally be available in the natural environment.

Cumbersome. Token economies can be cumbersome to implement, especially if there are multiple participants with multiple schedules of reinforcement. The system may require additional time and effort from the learner and the behavior analyst.

However, even though the effectiveness of the token economy has been shown repeatedly, Hackenberg (2018) states there is much still to learn:

> Work in the area of token systems is best served by a bidirectional interplay between laboratory and applied research, where applied questions inspire research on basic mechanisms. When based on and contributing to an analysis, applied research on token economies can be on the leading edge of theoretical advances, helping set the scientific research agenda. (393)

GROUP CONTINGENCIES

Thus far in this text we have focused primarily on how contingencies of reinforcement can be applied to individuals. However, applied research has also demonstrated how contingencies can be applied to groups. Behavior analysts have increasingly turned their attention toward group contingencies as interventions in such areas as decreasing disruptive behavior in public school settings (Stage & Quiroz, 1997), increasing leisure activities of adults with traumatic brain injury (Davis & Chittum, 1994), promoting abstinence from cigarette smoking (Meredith, Grabinski, & Dallery, 2011), improving behavior and academic performance of children in schools and classrooms (Skinner, Skinner, Skinner, & Cashwell, 1999; Popkin & Skinner, 2003; Skinner, Cashwell, & Skinner, 2000; Skinner, Skinner & Burton, 2009), and reducing problem behaviors on playgrounds (Lewis, Powers, Kelk, & Newcomer, 2002), to name just a few. Each of these applications has shown that group contingencies, properly managed, can be an effective and practical approach to changing the behavior of many people simultaneously (Stage & Quiroz, 1997). Longitudinal data collected over a 30-year period support the proposition that group contingencies with general education and exceptional children populations, applied across a myriad of settings, have been effective (Little, Akin-Little, & O'Neill, 2015).

Group Contingency Defined

In a **group contingency** a common consequence (usually, but not necessarily, a reward intended to function as reinforcement) is contingent on the behavior of one member of the group, the behavior of part of the group, or the behavior of everyone in the group. Group contingencies can be classified as dependent, independent, or interdependent (Litow & Pumroy, 1975).

Rationale for and Advantages of Group Contingencies

There are a number of reasons for using a group contingency in applied settings. First, it can save time during administration. Instead of repeatedly administering a consequence to each member of a group, the practitioner can apply one consequence to all members of the group. From a logistical perspective, a practitioner's workload may be reduced. A group contingency can be effective and economical, requiring fewer practitioners or less time to implement.

Another advantage is that a practitioner can use a group contingency in a situation in which an individual contingency is impractical (Hanley & Tiger, 2011). For example, a teacher attempting to reduce disruptive behaviors of several students might have difficulty administering an individual program for each pupil in the classroom. A substitute teacher, in particular, might find the use of a group contingency a practical alternative because her knowledge of the students' previous histories of reinforcement would be limited and the group contingency could be applied across a variety of behaviors, settings, or students.

A group contingency can also be used in cases in which the practitioner must resolve a problem quickly, as when serious disruptive behavior occurs. The practitioner might be interested not only in decreasing the disruptive behavior rapidly but also in building improved levels of appropriate behavior.

Furthermore, a group contingency can capitalize on peer influence or peer monitoring because this type of contingency sets the occasion for peers to act as change agents (Gable, Arllen, & Hendrickson, 1994; Skinner et al., 1999). Admittedly, peer pressure can have a detrimental effect on some people; they may become scapegoats, and negative effects may surface (Romeo, 1998). However, potentially harmful or negative outcomes can be minimized by structuring the contingency elements randomly (Kelshaw-Levering, Sterling-Turner, Henry, & Skinner, 2000; Popkin & Skinner, 2003).

Finally, practitioners can establish a group contingency to facilitate positive social interactions and positive behavioral supports within the group (Kohler, Strain, Maretsky, & DeCesare, 1990). For example, a teacher might establish a group contingency

for a student or a group of students with disabilities. The students with disabilities might be integrated into the general education classroom, and a contingency could be arranged in such a way that the class would be awarded free time contingent on the performance of one or more of the students with disabilities.

Independent Group Contingencies

An **independent group contingency** is an arrangement in which a contingency is presented to all members of a group, but reinforcement is delivered only to those group members who meet the criterion outlined in the contingency (see Figure 28.2). Independent group contingencies are frequently combined with contingency contracting and token reinforcement programs because these programs usually establish reinforcement schedules independent of the performance of other members of the group.

Brantley and Webster (1993) used an independent group contingency in a general education classroom to decrease the disruptive behavior of 25 fourth-grade students. After collecting data on off-task behavior, call-outs, and out-of-seat behavior, the teachers posted rules related to paying attention, seeking the teachers' permission before talking, and remaining in their seats. An independent group contingency was established whereby each student could earn a checkmark next to his or her name on a list that was posted publicly in the room during any of the intervals that marked the observation periods during the day. When a student emitted an appropriate or prosocial behavior, a checkmark was registered. The criterion for earning a reward was increased from four to six checkmarks over 4 out of 5 days per week.

Results showed that after 8 weeks, the total number of combined disruptions (e.g., off-task behavior, call-outs, and out-of-seat behavior) decreased by over 70%, and some off-task behaviors (e.g., not keeping hands to self) were eliminated completely. The teacher's satisfaction with the approach was positive, and parents reported that they were able to understand the procedures that were in place for their children at school. Brantley and Webster (1993) concluded:

> The independent contingency added structure for students by using clear time intervals and clarified teacher expectations by limiting and operationally defining rules to be followed, monitoring behavior consistently, and setting attainable criteria for students. (p. 65)

A →	B →	C
Criterion stated for all group members*	Criterion met	S^{R+} for *each* member achieving criterion

*(E.g., "Each student who spells 9 out of 10 words correctly on the test Friday will earn 10 bonus points.")

Maupin, 2010, *Journal of Applied Behavior Analysis, 43*, 318. Reproduced with permission of John Wiley & Sons,Inc.

Dependent Group Contingencies

Under a **dependent group contingency**, the reward for the whole group is dependent on the performance of an individual student or small group. Figure 28.3 illustrates the dependent group contingency as a three-term contingency. The contingency operates like this: If an individual (or small group within the total group) performs a behavior to a specific criterion, the group shares the reinforcer. The group's access to the reward depends on the individual's (or small group's) performance. If the individual performs below the criterion, the reward is not delivered. When an individual, or small group, earns a reward for a class, the contingency is sometimes referred to as the **hero procedure**. According to Kerr and Nelson (2002), the hero procedure can facilitate positive interactions among students because the class as a whole benefits from the improved behavior of the student targeted for the group contingency.

Gresham (1983) used an interesting variation of the hero procedure within a dependent group contingency whereby the contingency was applied at home, but the reward was delivered at school. In this study, an 8-year-old boy who was highly destructive at home (e.g., set fires, destroyed furniture) earned good notes for nondestructive behavior at home. Billy received a good note—a daily report card—each day that no destructive acts took place. Each note was exchangeable for juice, recess, and five tokens at school the next day. After Billy received five good notes, the whole class received a party, and Billy served as the host. Gresham reported that the dependent group contingency reduced the number of destructive behaviors at home, and represented the first application of a dependent group contingency in a combined home–school setting.

Interdependent Group Contingencies

An **interdependent group contingency** is one in which all members of a group must meet the criterion of the contingency (individually *and* as a group) before any member earns the reward (Elliot, Busse, & Shapiro, 1999; Kelshaw-Levering et al., 2000; Lewis et al., 2002; Skinner et al., 1999; Skinner et al., 2000) (see Figure 28.4). Theoretically, interdependent group contingencies have a value-added advantage over dependent and independent group contingencies insofar as they yoke students to achieve a common goal, thereby capitalizing on peer pressure and group cohesiveness.

A ⟶ B ⟶ C

Criterion stated for all group members* | Criterion met | S^{R+} for whole group *if* all members of the group achieve criterion

*(E.g., "Each student must complete at least four science projects by the 6th week in the term in order for the class to go on the field trip.")

Figure 28.4 An interdependent group contingency.

The effectiveness of dependent and interdependent group contingencies may be enhanced by randomly arranging some or all components of the contingency (Popkin & Skinner, 2003). That is, randomly selected students, behaviors, or reinforcers are targeted for the contingency (Kelshaw-Levering et al., 2000; Skinner et al., 1999). Kelshaw-Levering and colleagues (2000) demonstrated that randomizing either the reward alone or multiple components of the contingency (e.g., students, behaviors, or reinforcers) was effective in reducing disruptive behavior.

Procedurally, an interdependent group contingency can be delivered (a) when the group as a whole meets the criterion, (b) when the group achieves a mean group score (Kuhl, Rudrud, Witts, & Schulze, 2015), or (c) based on the results of the Good Behavior Game or the Good Student Game. In any case, interdependent group contingencies represent an "all or none" arrangement. That is, all students earn the reward or none of them do (Popkin & Skinner, 2003).

Total Group Meets Criterion

Lewis and colleagues (2002) used the *total group meets criterion* variation to reduce the problem playground behaviors of students enrolled in a suburban elementary school. After a faculty team conducted an assessment of problematic playground behaviors, social skill instruction in the classroom and on the playground was coupled with a group contingency. During social skills instruction, students learned how to get along with friends, cooperate with each other, and be kind. During the group contingency, students earned elastic loops they could affix to their wrists. After recess, students placed the loops in a can on the teacher's desk. When the can was full, the group earned a reinforcer. Figure 28.5 shows the results of the social skills plus group contingency intervention across three recess periods during the day.

Group Averaging

Baer and Richards (1980) used a group averaging interdependent group contingency to improve the math and English performance of 5 elementary-aged students. In their study, all of the students in a class of 10, including the 5 target students, were told they would earn 1 extra minute of recess for each point of class improvement beyond the previous weekly average. Also, all students were given a contract stating this same contingency. The extra recess was awarded every day of the following week. For example, if the students' weekly averages exceeded their previous weekly averages by 3 points, they would receive 3 minutes of extra recess every day of the following week. The results of this 22-week study showed that all students improved when the group contingency was in effect.

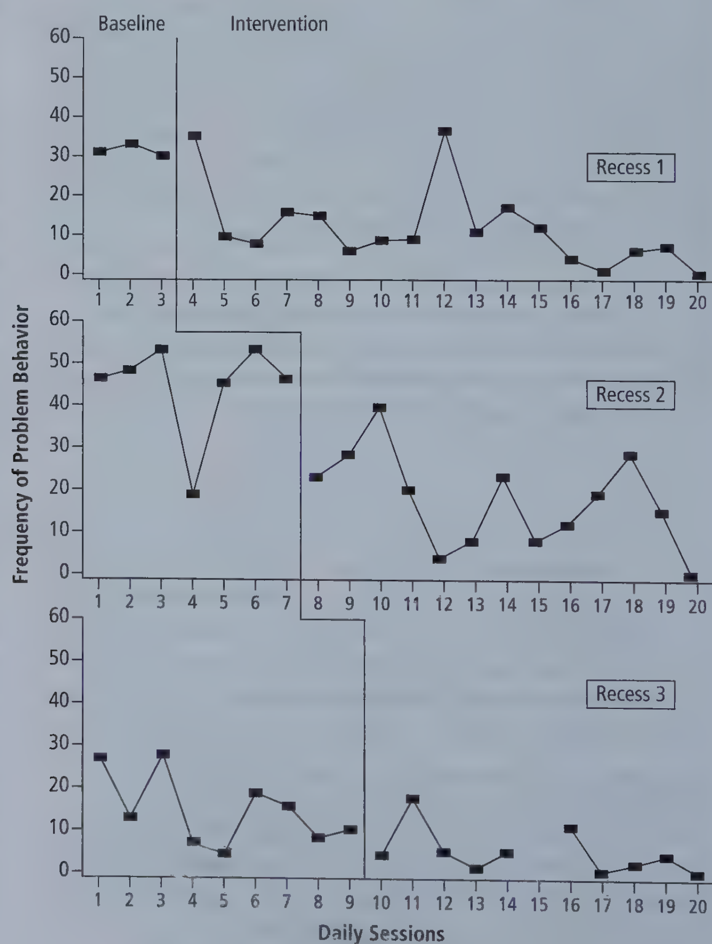

Figure 28.5 Frequency of problem behaviors across recess periods. Recess 1 was composed of second- and fourth-grade students, Recess 2 was composed of first- and third-grade students, and Recess 3 was composed of fifth- and sixth-grade students. Kindergarten students were on the playground across Recess 1 and 2.

Kuhl et al. (2015) used an interdependent group contingency as part of a comparison study on the effects of group versus individual goal setting on the increased level of physical activity of 4 selected students (2 males and 2 females) across two classrooms with total class populations of 25 to 30 students, respectively. In their study, students received a pedometer that registered their total number of steps during a 24-hour period, 4 days per week (Monday through Thursday). Prior to launching the study, teachers selected five activities from a list of 20 potential items thought to be reinforcing to the students. Ultimately, from that list of five activities, students voted for 15 minutes of extra free time as their reinforcer. Recess was awarded on Fridays.

A counterbalanced reversal design (ABACX) was used where X served as the best phase. During baseline, students received a calibrated pedometer, set to zero steps, which the students wore for a 24-hour period, excluding time spent bathing/swimming, or sleeping, over the course of the study. During baseline, students could not see the number of steps taken, as the pedometer was masked. Data were recorded daily, 4 days per week. During the Classroom Cumulative Total Condition, a cumulative total goal was determined by averaging each participant's daily step count, and then adding 1500 steps per student per day to that average.[1] Fifteen minutes of extra free time was awarded on Friday if the cumulative total of steps exceeded the goal. Pedometers were unmasked in this condition. Each day, the teachers publically posted cumulative daily step counts and provided verbal feedback to show progress toward their goal. When the Individual Goals Condition was introduced, the children were given their unmasked pedometers, but they met with the teacher, who informed them of their individual goal, which was determined by averaging the previous 4 days of data and adding 1500 steps to that figure. If a student met his goal, he was praised. If the goal was not met, the teacher encouraged the student to keep trying to meet the goal. Extra free time was administered on Friday if 80% of the students met their individual goal each day. Finally, a feedback schedule-thinning phase was introduced. During the 2-day condition, step count and recording occurred on only 2 days. During the 4-day condition, counts and recordings occurred on only 1 day per week. Reinforcement conditions remained the same.

The results of the study (see Figure 28.6) showed that step counts increased under both the cumulative and individual

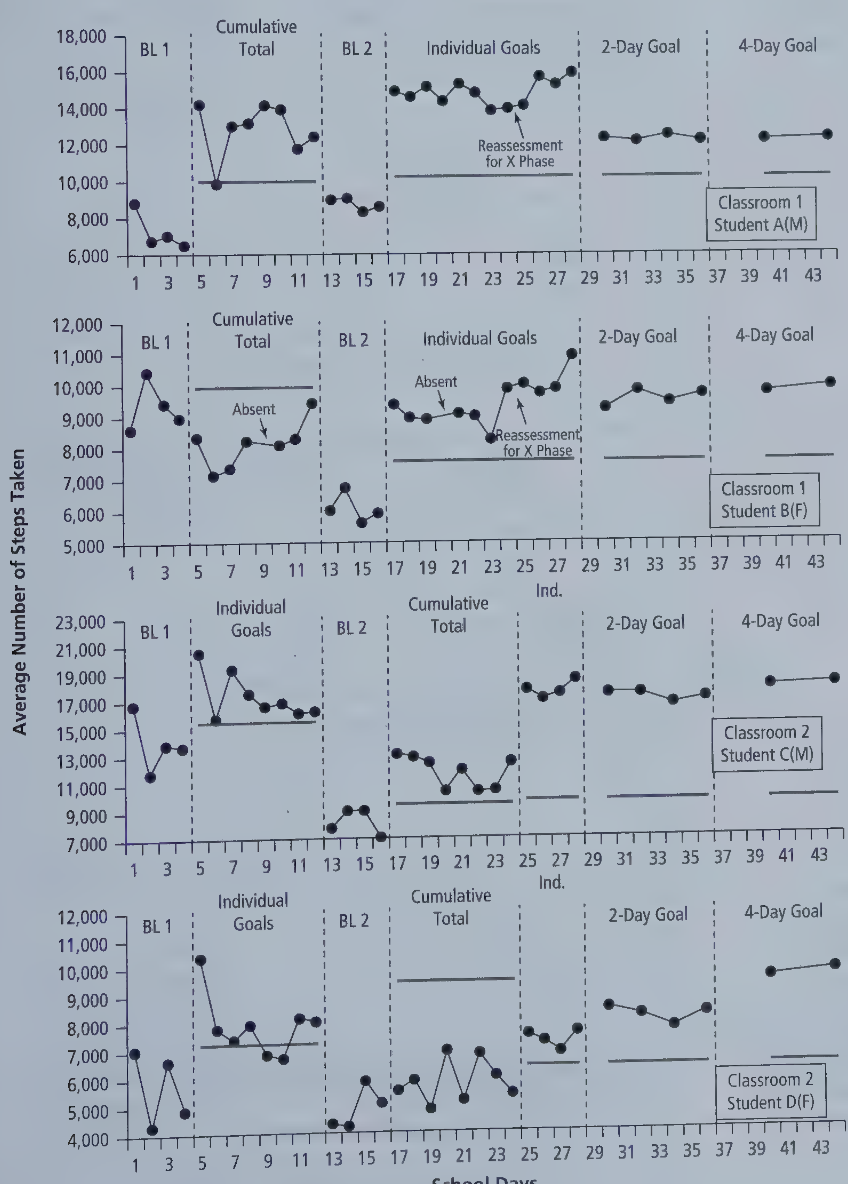

Figure 28.6 Total number of steps by four randomly selected students during cumulative and individual goal setting by four students.

From "Classroom-based Interdependent Group Contingencies Increase Children's Physical Activity," by S. Kuhl, E. H., Rudrud, B. N. Witts, and K. A. Schulze, 2015, *Journal of Applied Behavior Analysis, 48*, p. 609. Reproduced with permission of John Wiley & Sons,Inc.

contingencies; however, higher step counts were registered under the individual contingency regardless of its order during counterbalancing. Anecdotal evidence, collected after the study, suggested that under the individual contingency students engaged in extra walking practices that otherwise may not have occurred. That is, they walked in the gym before school, played action games with peers after school, and had parents drop them off farther from school each day to increase step counts. The fact that step counts during the thinning phase were still higher than baseline, but lower than during the individual phase, suggested the important role of daily feedback in establishing and maintaining increased step counts.

Good Behavior Game

Barrish, Saunders, and Wolf (1969) first investigated the **Good Behavior Game** (GBG) as an interdependent group contingency to address a variety of student classroom disruptive behaviors. Procedurally, to play the GBG a class (or group) is divided into two or more teams. Prior to the game being played, the teams are told that whichever team has the *fewest* marks against it at the end of the game will earn a reward. Each team is also told that it can win a reward if it has fewer than a specified number of marks (a differential reinforcement of low rates [DRL] schedule). Data reported by Barrish et al. show that this strategy can be an effective method of reducing disruptive behavior in the classroom. When game conditions were in effect during math or reading, talking-out and out-of-seat behaviors occurred at low levels. When game conditions were not in effect, disruptive behaviors occurred at much higher levels (see Figure 28.7).

In the Good Behavior Game, teacher attention is directed toward observing and recording occurrences of misbehavior, with the incentive that if one or more teams have fewer than the criterion number of infractions, a reinforcer is delivered. The advantage of the Good Behavior Game is that competition can occur within teams, across teams, or against a criterion.

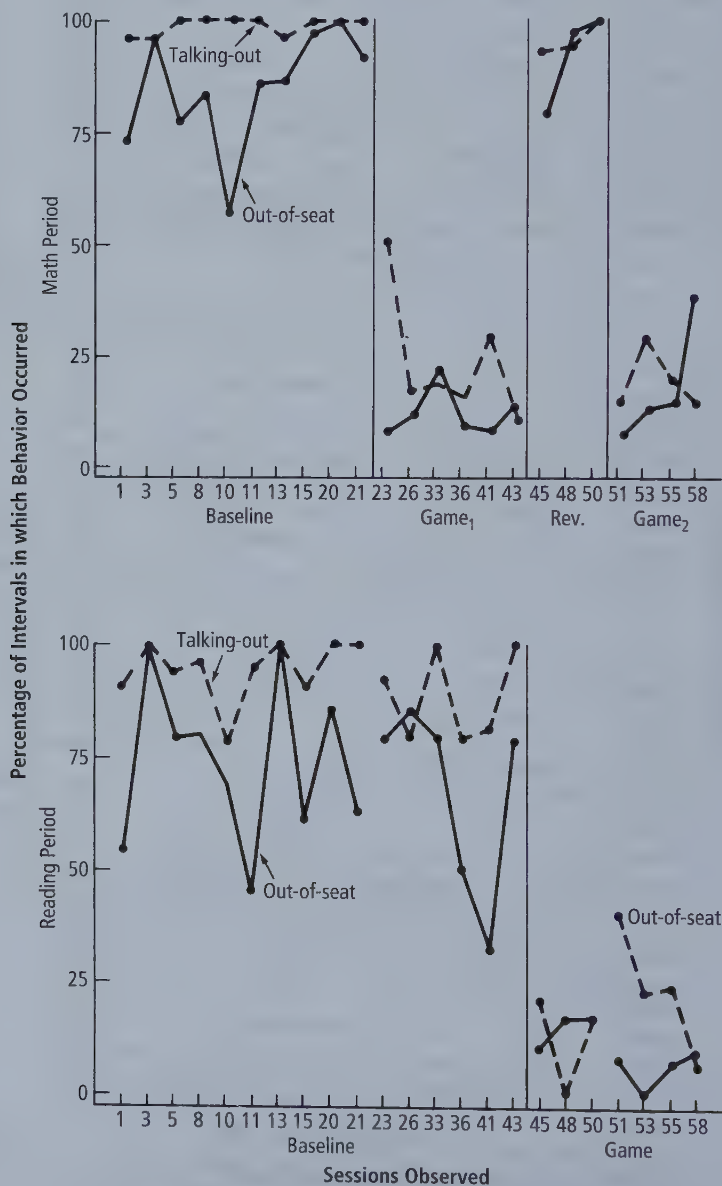

Figure 28.7 Percentage of 1-min intervals containing talking-out and out-of-seat behaviors in a classroom of 24 fourth-grade children during math and reading periods.

From "Good Behavior Game: Effects of Individual Contingencies for Group Consequences on Disruptive Behavior in a Classroom" by H. H. Barrish, M. Saunders, and M. M. Wolf, 1969, *Journal of Applied Behavior Analysis*, *2*, p. 122. Reproduced with permission of John Wiley & Sons,Inc.

Since Barrish et al.'s groundbreaking study, a number of researchers have investigated the GBG across a broad spectrum of settings and age groups, and in combination with other procedures (for reviews, see Little, Akin-Little, & O'Neill, 2015; Tingstrom, Sterling-Tuner, & Wilczynski, 2006). Further, several investigators have demonstrated its effectiveness as a preventative measure (Embry, 2002; Lannie & McCurdy, 2007; Van Lier, Van Der Sar, Muthen, & Crijen, 2004). By implementing a successful GBG program with children who are young—but disruptive and out-of-control—the goal is to "prevent" even worse outbursts in middle or high school by presumably socializing students at an early age to expectations, rules, and contingencies of reinforcement.

Donaldson, Vollmer, Krous, Downs, and Berard (2011), for example, conducted a replication of the Good Behavior Game with five teachers across their respective kindergarten classes, each experiencing disruptive students during morning group work that interfered with the goals of the lesson. After collecting baseline data on the total rate of disruptive behaviors, the class was divided into two teams, each containing, based on the teacher's judgment, a comparable number of disruptive students. During the GBG, teachers provided rules related to the children staying on their carpet patches, keeping their hands and feet to themselves, and speaking when called upon. If a disruptive behavior occurred, the experimenter—and later the teacher—placed a mark on the board and simultaneously announced aloud what rule was broken by a member of that team. One team won the game by having fewer points than the other team, or both teams won if they both met a criterion set by the teacher of an 80% or better reduction from baseline levels of misbehavior.

Figure 28.8 shows that under the GBG contingency, disruptive behavior decreased across all classrooms. Further, low levels of disruptive behavior continued after the experimenter shifted game implementation to the teacher, despite treatment integrity data indicating that teachers did not implement all procedures as trained. In short, even though implementation steps were likely compromised due to teachers simultaneously conducting an academic lesson, results were still robust.

Finally, teachers reported anecdotally that the children, when offered a choice, "voted" to continue playing the game for the rest of the year, and four teachers continued the game the following year. Donaldson et al. (2011) suggest that the (a) rewards that the students earned for winning may have served as social reinforcers, (b) hash marks on the board for disruptive behavior may have served as punishers, or (c) children's social interplay during the game (or later) may have affected the overall outcome. In any case, this study showed the powerful effects of the GBG with a very young population of students.

Kleinman and Saigh (2011) also conducted a successful replication study of the GBG with a class of extremely disruptive high school–level students attending a multiethnic public high school in a large urban area (Harlem, New York). Students were

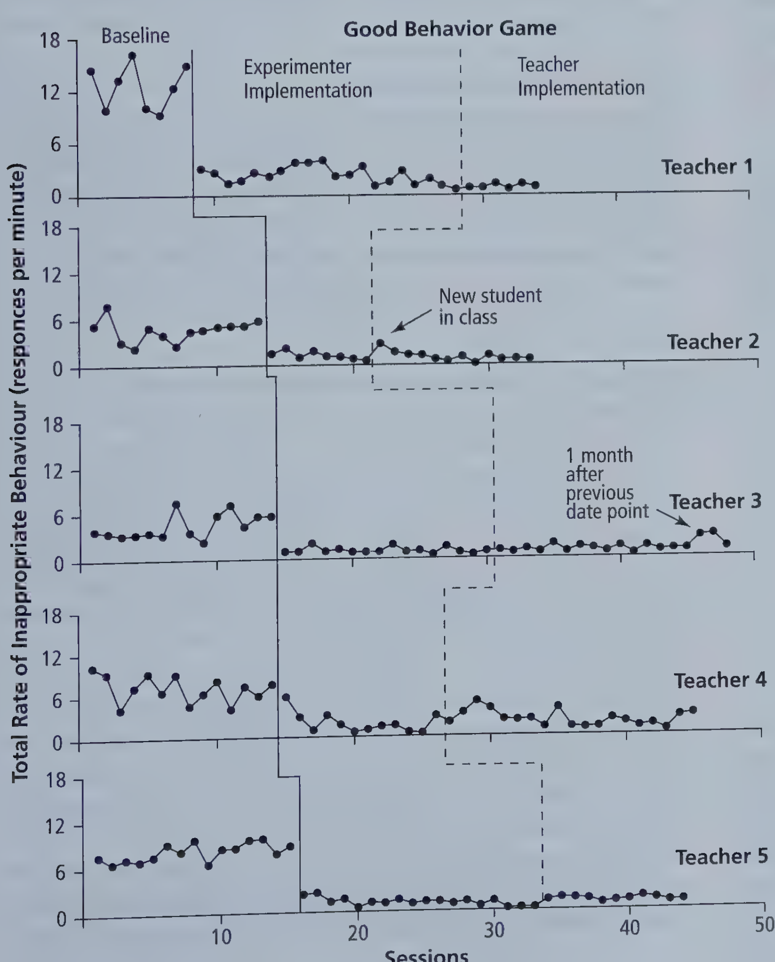

Figure 28.8 Rate of inappropriate behavior by kindergarten students as a function of the Good Behavior Game implemented by the experimenter and classroom teachers.

From "An Evaluation of the Good Behavior Game in Kindergarten Classrooms," by J. M. Donaldson, T. R. Vollmer, T. Krous, S. Downs, and K. P. Berard, 2011, *Journal of Applied Behavior Analysis*, *44*, pp. 605–609. Reproduced with permission of John Wiley & Sons,Inc.

observed to be so highly disorderly, with out-of-seat behavior, calling out, and physical altercations in class, that a previous teacher resigned her position. The new teacher's reception was met with cursing, screaming, and throwing objects. To address this situation, the new teacher conducted a reinforcer preference phase that was used to determine rewards that could be delivered given the ages of the students and budget constraints imposed by circumstances. A reversal design was employed that involved a short adaptation period to acclimate the students to observers in the class, followed by a Baseline I, GBG, Baseline II, and GBG 2.

During Baseline I, students were divided into two teams with approximately equal numbers of disruptors on each team. Further, the teacher posted a list of "expectations" for student behavior on the front board and read them before each session. Finally, all disruptions were handled in the past manner (e.g., teacher reprimands, removal from the classroom). During GBG 1, the teacher announced to the students that the teams would now compete with each other for daily and weekly prizes. They were told that any occurrence of defined target behaviors would result in the disruptor being named aloud and a mark placed against that disruptor's team. At the end of the period, the team with fewer marks would earn a prize (e.g., bite-sized candy). A weekly prize (i.e., a pizza party, cupcakes) would be awarded to the team with fewer marks for the week. Baseline II conditions replicated Baseline I. GBG 2 replicated GBG 1. A follow-up phase was conducted several weeks after the study's completion. Results indicated that when baseline conditions were in effect, extremely high levels of disruptive behavior occurred. When GBG conditions were in effect, all levels of disruptive behavior decreased markedly, and remained so during a successive follow-up phase (see Figure 28.9).

Kleinman and Saigh concluded that the GBG (a) reduced the disruptive target behaviors rapidly, (b) provided strong external validity of the efficacy of the GBG for older students, and (c) produced convincing social validity approval data from students in an inner-city, multiethnic setting. That is, the students themselves reported that they could observe the dramatic effects of improved behavior during GBG phases.

Good Student Game

The *Good Student Game* combines an interdependent group contingency (like the Good Behavior Game) with an added self-monitoring twist (Babyak, Luze, & Kamps, 2000). Basically, the Good Student Game is intended for implementation during independent seatwork periods when problematic behaviors surface. In the Good Student Game, the teacher (a) chooses target behaviors to modify, (b) determines goals and rewards, and (c) determines whether group or individual monitoring (or both) will occur.

Students are trained in the Good Student Game using a model-lead-test instructional sequence: Students are arranged in clusters of four or five, the target behaviors are defined, examples and nonexamples are provided, practice occurs under teacher supervision, and one or more students record their own or the group's performance. Table 28.2 shows how the Good Student Game compares to the Good Behavior Game. Note that two distinctions relate to target behaviors, the delivery of rewards, and feedback.

Guidelines for Implementing a Group Contingency

Implementing a group contingency requires as much preplanning as any other behavior change procedure. Presented here are six guidelines to follow before and during the application of a group contingency.

Choose an Effective Reward

One of the more important aspects of a group contingency is the strength of the consequence; it must be strong enough to serve as an effective reward. Practitioners are advised to use generalized conditioned reinforcers or reinforcer menus at every opportunity. Both of these strategies individualize the contingency, thereby increasing its power, flexibility, and applicability.

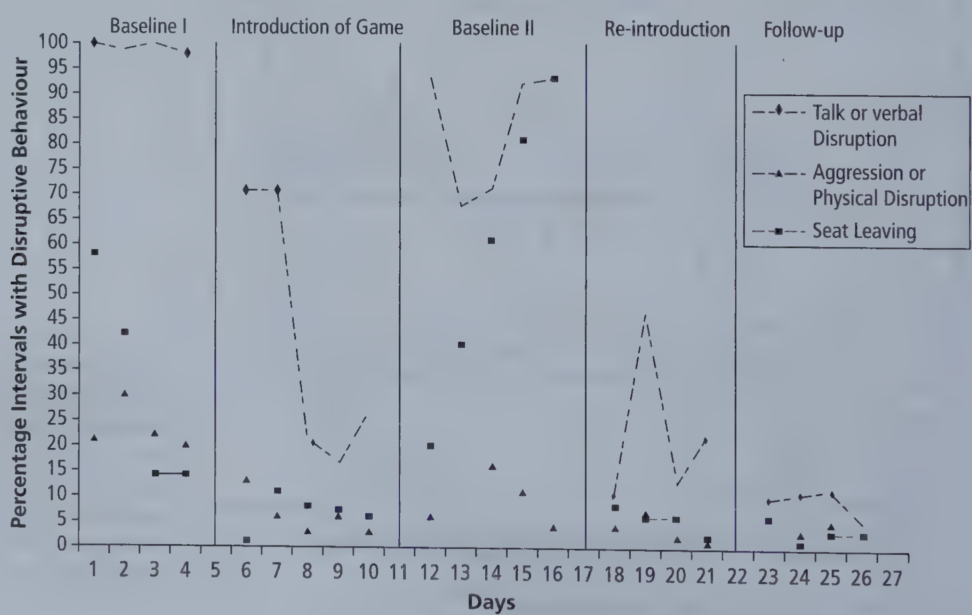

Figure 28.9 Disruptive behavior by general education high school students as a function of the Good Behavior Game.

From "The Effects of the Good Behavior Game on the Conduct of Regular Education New York City High School Students," by K. E. Kleinman and P. A. Saigh, 2011, *Behavior Modification, 35*(1), p. 101. Copyright 2011 by Sage Publications. Reprinted by permission.

TABLE 28.2 Components of the Good Behavior Game and the Good Student Game

Component	Good Behavior Game	Good Student Game
Organization	Students play in teams.	Students play in teams or as individuals.
Management	Teacher monitors and records behavior.	Students self-monitor and record their behavior.
Target behaviors	Behaviors are stated as rule breaking or rule following.	Behaviors are stated as rule following.
Recording	Teachers record incidents of rule-breaking behaviors as they occur.	Students record rule-following behaviors on a variable-interval schedule.
System of reinforcement	Positive.	Positive.
Criterion for reinforcement	Teams must not exceed a set number of rule-breaking behaviors.	Groups or individuals achieve or exceed a set percentage of rule-following behaviors.
Delivery of reinforcement	Dependent on group performance.	Dependent on individual or group performance.
Feedback	Teacher provides feedback when rule-breaking behaviors occur.	Teacher provides feedback at intervals. Praise and encouragement are presented during the game to reinforce positive behaviors.

Determine the Behavior to Change and Any Collateral Behaviors That Might Be Affected

Let us suppose a dependent group contingency is established in which a class receives 10 minutes of extra free time, contingent on the improved academic performance of a student with developmental disabilities. Obviously, the teacher will need to collect data on the student's academic performance. However, data might also be collected on the number of positive interactions between the student and her classmates without disabilities within and outside the room. An additional benefit of using a group contingency might be the positive attention and encouragement that the student with developmental disabilities receives from her classmates.

Set Appropriate Performance Criteria

If a group contingency is used, the persons to whom the contingency is applied must have the prerequisite skills to perform the specified behaviors. Otherwise, they will not be able to meet the criterion and could be subject to ridicule or abuse (Stolz, 1978).

According to Hamblin, Hathaway, and Wodarski (1971), the criteria for a group contingency can be established by using the average-, high-, or low-performance levels of the groups as the standard. In an average-performance group contingency, the mean performance of the group is averaged, and reinforcement is contingent on the achievement of that mean score or a higher score. If the average score for a math exercise was 20 correct problems, a score of 20 or more would earn the reward. In a high-performance group contingency, the high score determines the level of performance needed to receive the reward. If the high score on a spelling test was 95%, only students achieving a score of 95% would receive the reward. In the low-performance group contingency, the low-performance score determines the reinforcer. If the low score on a social studies term paper was C, then students with a C or better would receive the reinforcer.

Hamblin et al. (1971) indicated that differential effects can be noted with these performance contingencies. Their data show that academically challenged students performed the worst under a high-performance contingency, whereas gifted students performed best under this contingency. The data of Hamblin and colleagues suggest that a group contingency can be effective in improving behavior, but it should be applied with the understanding that effectiveness may vary for different members of the group.

Combine with Other Procedures When Appropriate

According to LaRowe, Tucker, and McGuire (1980), a group contingency can be used alone or in combination with other procedures to systematically change performance. The LaRowe and colleagues study was designed to reduce excessive noise levels in an elementary school lunchroom; their data suggest that differential reinforcement of low rates of behavior (DRL) can be incorporated easily into a group contingency. In situations in which higher levels of group performance are desired, differential reinforcement of high rates of behavior (DRH) can be used. With either DRL or DRH, the use of a changing criterion design may facilitate the analysis of treatment effects.

Select the Most Appropriate Group Contingency

The selection of a specific group contingency should be based on the overall programmatic goals of the practitioner, the parents (if applicable), and the participants whenever possible. For instance, if the group contingency is designed to improve the behavior of one person or a small group of individuals, then perhaps a dependent group contingency should be employed. If the practitioner wants to differentially reinforce appropriate behavior, then an independent group contingency should be considered. But if the practitioner wants each individual within a group to perform at a certain level, then an interdependent group contingency should be chosen. Regardless of which group contingency is selected, the ethical issues discussed in Chapter 31 must be addressed.

Monitor Individual and Group Performance

When a group contingency is employed, practitioners must observe group and individual performance. Sometimes a group's performance improves, but members within the group do not improve, or at least do not improve as fast (Jowett Hirst et al., 2016). Some members of the group might even attempt to sabotage the group contingency, preventing the group from achieving the reinforcement. In these cases, individual contingencies should be arranged for the saboteurs that might combine the group contingency with other behavior reduction or behavior building procedures.

Future Applications of Group-Oriented Contingencies

Abundant evidence confirms that group-oriented contingencies have demonstrated effectiveness in classroom settings for individuals and groups, and across a range of instructional, therapeutic, and play-based settings (for a review, see Maggin, Johnson, Chafouleas, Ruberto, & Berggren, 2012). However, despite over 50 years of empirical demonstrations of their effectiveness, group contingencies, particularly the Good Behavior Game and its variations, have not been widely adopted, with an ever-wider range of populations yet to be explored (Vollmer, Joslyn, Rubow, Kronfli, & Donaldson, 2016).

Researchers might also turn their attention to evaluating group-oriented contingencies on larger issues facing society (e.g., global warming, recycling, reducing armed conflict, drug abuse). Some initial efforts using Internet-based group contingences have led to promising results with behaviors known to be systemic and addictive (Dallery, Raiff, & Grabinski, 2013; Dallery, Meredith, Jarvis, & Nuzzo, 2015).

CONTINGENCY CONTRACTING

A **contingency contract** (also called a *behavioral contract*) is a document that specifies a contingent relationship between the completion of a target behavior and access to, or delivery of, a specified reward. Contingency contracts stipulate how two or more people will behave toward each other. Such quid pro quo agreements make one person's behavior (e.g., preparing dinner) dependent on the other person's behavior (e.g., washing and putting away the dishes by a prescribed time the night before). Although verbal agreements may be considered contracts in the legal sense, they are not contingency contracts because the degree of specificity in designing, implementing, and evaluating a contingency contract far exceeds what is likely to occur in a verbal arrangement between parties. In addition, the act of signing a contingency contract and its prominent visibility during execution are integral parts of contingency contracts.

Contingency contracts have been used to improve academic performance (Wilkinson, 2003), weight control (Solanto, Jacobson, Heller, Golden, & Hertz, 1994), adherence to medical regimens (Miller & Stark, 1994), and athletic skills (Simek, O'Brien, & Figlerski, 1994). A compelling advantage of contingency contracts is their ability to be implemented alone or in packaged programs that incorporate two or more interventions concurrently (De Martini-Scully, Bray, & Kehle, 2000). In their meta-analysis of single-case research on behavior contracts, Bowman-Perrott, Burke, deMarin, Zhang, and Davis (2015) concluded that contingency contracts are beneficial for children and youth "regardless of grade level, gender, or disability status" (p. 247); are easily used by a wide range of practitioners; and can be combined with other behavior change interventions (e.g., De Martini-Scully et al., 2000; Navarro, Aguilar, Aguilar, Alcalde, & Marchena, 2007).

Contingency Contract Components

A contingency contract specifies the task and who is to perform it and the reward and who is to deliver it contingent on task completion. Figure 28.10 shows a contingency contract between a 10-year-old boy and his parents to help him get ready for school on time in the morning. This contract includes the two components required in all contingency contracts: task description and reward description—plus an optional task record.

Task

The task component consists of four parts. *Who* is the person who will perform the task and receive the reward—in this case, Lee. *What* is the task or behavior Lee must perform—getting ready for school. *When* identifies the time that the task must be completed—every school day. *How Well* is the most important part of the task component, and perhaps of the entire contract. It calls for the specifics of the task. Sometimes it is helpful to list a series of steps or subtasks so that the person can use the contract as a checklist of what must be done. Including a photo showing what the completed task should look like is helpful for some tasks (e.g., cleaning one's bedroom, setting the table for dinner). Any exceptions should be written in this part.

Reward

The reward side of a contract must be as complete and specific as the task side. Teachers and parents are usually good at specifying the task component of a contract; they know what they want their students or children to do. When it comes to the reward, however, specificity is lost and problems arise. Reward statements such as "Can watch some television" or "Will play catch when I get a chance" are not explicit, specific, or fair to the person completing the task.

On the reward side, *Who* is the person who will judge task completion and deliver the reward. With Lee's getting-ready-for-school contract, his mother is that person. *What* is the reward. *When* specifies the time that the reward can be received by the person earning it. With any contract it is crucial that the reward come *after* successful task completion. However, many rewards cannot be delivered immediately following task completion. In addition, some rewards have built-in, limited availability and can be delivered only at certain times (e.g., seeing the hometown baseball team play). Lee's contract specifies that his reward, if earned, will be received on Friday nights. *How Much* is the amount of reward that can be earned by completing the task. Any bonus contingencies should be included; for example, "By meeting her contract Monday through Friday, Ellie will earn bonus rewards on Saturday and Sunday."

CONTRACT

TASK

Who: Lee

What: Get ready for school

When: Each school day

How Well: Out of bed, dressed, cereal finished by 7:15. No more than 1 reminder from Mom or Dad.

REWARD

Who: Mom

What: Lee has a friend stay over

When: Friday night after perfect week

How Much: Friend can come home with Lee after school and stay overnight. Boys get pizza for late night treat.

Figure 28.10 Example of a contingency contract.

Adapted from "*Sign Here: A Contracting Book for Children and Their Parents*" (2nd ed.) by J. C. Dardig and W. I. Heward, 2016. Copyright 1995 by J. C. Dardig and W. L. Heward. Used with Permission.

Task Record

Including a place on the contract to record task completion serves two purposes. First, recording task completion and reward delivery on the contract sets the occasion for all parties to review the contract regularly. Second, if a certain number of task completions are required to earn the reward, a checkmark, smiley face, or star can be placed on the task record each time the task is completed successfully. Marking the contract in this manner helps the person remain focused until the assignment is completed and the reward is earned. Lee's mother used the top row of boxes in the task record to record the days of the school week. In the middle row of boxes she placed gummed stars each day Lee met the conditions of his contract. In the bottom row, Lee's mother wrote comments about the progress of his contract.

Applications of Contingency Contracting

Contracting in the Classroom

Teachers have employed contracting to address specific discipline, performance, and academic challenges (De Martini-Scully et al., 2000; Flood & Wilder, 2002; Kehle, Bray, Theodore, Jenson, & Clark, 2000; Mruzek, Cohen, & Smith, 2007; Ruth, 1996). Newstrom and colleagues (1999), for instance, used a contingency contract with a middle school student with behavior disorders to improve the written mechanics associated with spelling and written language. After collecting baseline data on the percentage of capitalization and punctuation marks used correctly across spelling and sentence writing, a contingency contract was negotiated with and signed by the student that specified that improved performance would yield free time on the classroom computer. The student was reminded of the terms of the contract before each language arts class that included spelling worksheets and journal writing (i.e., sentences).

Figure 28.11 shows the results of the contingency contracting intervention. When baseline was in effect for spelling and written sentences respectively, mean scores for both variables were in the 20% correct range. When contracting was initiated, the student's performance for spelling and written sentences increased immediately to an average of approximately 84% correct. The authors also reported positive anecdotal evidence related to spelling and written language from other teachers with whom this student interacted.

Wilkinson (2003) used a contingency contract to reduce the disruptive behavior of a first-grade student. Disruptive behaviors included being off task, refusals to comply with work assignments and instructions, fighting with peers, and temper tantrums. A behavioral consultation effort was launched with the classroom teacher that included problem identification, analysis, intervention, and evaluation. Contingency contracting consisted of the student earning preferred rewards and social praise from the teacher for three behaviors: increased time on task, appropriate interactions with other children, and compliance with teacher requests. Observations of her behavior over 13 sessions of baseline and contingency contracting showed a decrease in the percentage of intervals with disruptive behavior when the contingency contract was in effect. Wilkinson reported

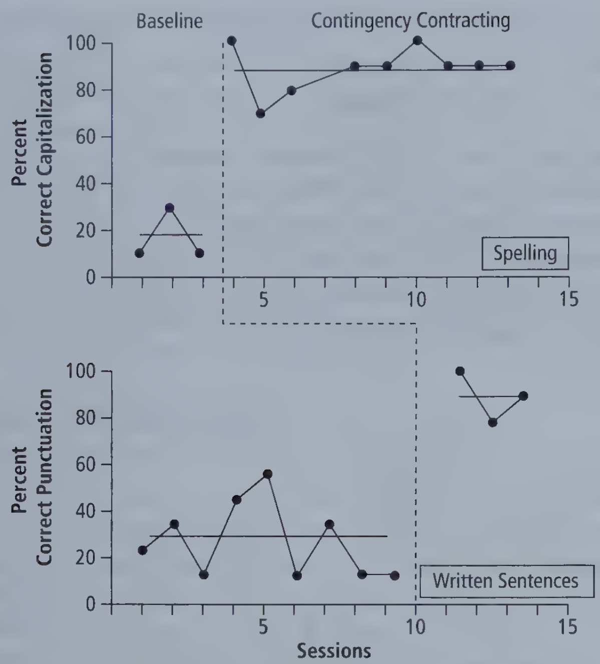

Figure 28.11 Percentage of capitalization and punctuation marks used correctly on spelling worksheets and journal writing during baseline and contingency contracting.

From "The Effects of Contingency Contracting to Improve the Mechanics of Written Language with a Middle School Student with Behavior Disorders," by J. Newstrom, T. F. McLaughlin, and W. J. Sweeney, 1999, *Child & Family Behavior Therapy*, *21*(1), p. 44. Copyright 1999 by The Haworth Press, Inc. Reprinted by permission.

that the student's disruptive behavior decreased substantially and remained low during a 4-week follow-up period.

Ruth (1996) conducted a 5-year longitudinal study that blended contingency contracting with goal setting with students who had emotional and behavioral problems. After students negotiated contracts with their teachers, a goal-setting component was added that included statements about their daily and weekly goals and the criterion levels for success. Results for the 37 out of 43 students who finished the program after 5 years showed that 75% of daily goals, 72% of weekly goals, and 86% of total goals were reached. Ruth summarized the beneficial effects of combining strategies: "When [goal-setting] methods are incorporated into a contract, the motivational aspects of behavior contracting and goal setting may combine to produce maximum effort and success" (p. 156).

Contracting in the Home

Miller and Kelley (1994) combined contingency contracting and goal setting to improve the homework performance of four preadolescent students with histories of poor homework completion and who were at risk for other academic problems (e.g., procrastination, being off task, errors with submitted work). During baseline, parents recorded their children's homework time on task, type and accuracy of problem completion, and number of problems completed correctly. Subsequently, parents and children entered into a goal setting and contingency contracting phase that was preceded by parent training on how to set and negotiate goals and write contracts. Each night, parents and children established their respective goals and negotiated a compromise goal based on that interaction. Each week, renegotiations occurred for tasks, rewards, and sanctions should the contract not be met. A recording sheet was used to measure progress.

Figure 28.12 shows the results of the study. When goal setting was combined with contingency contracting, accuracy performance increased for all students. Miller and Kelley's findings reaffirm the notion that contingency contracting can be combined successfully with other strategies to produce functional outcomes.

Clinical Applications of Contracting

Flood and Wilder (2002) combined contingency contracting with functional communication training to reduce the off-task behavior of an elementary-aged student diagnosed with attention-deficit hyperactivity disorder (ADHD) who had been referred to a clinic-based program because his off-task behavior had reached alarming levels. Antecedent assessment, functional communication training, and contingency contracting were conducted in a therapy room located in the clinical facility. Specifically, antecedent assessments were conducted to determine the level of off-task behavior when the difficulty of academic tasks varied from easy to difficult and therapist attention varied from low to high. A preference assessment was also conducted. Using discrete trial training, the student was taught to raise his hand for assistance with tasks (e.g., "Can you help me with this problem?"). The therapist sat nearby and responded to appropriate requests for assistance and ignored other vocalizations. Once requesting assistance was mastered, the contingency contract was established whereby the student could earn preferred items, identified through the assessment, contingent on accurate task completion. The results showed that during baseline, off-task performance was high for math division and word problems. When the intervention was introduced, an immediate reduction in off-task behavior was noted for division and word problems. Also, the student's accuracy in completing the division and word problems improved as well. Whereas during baseline conditions he solved correctly 5% and 33% of the division and word problems, respectively, during intervention he solved 24% and 92% of the problems correctly.

Using Contracting to Teach Self-Management Skills to Children

Ideally, contingency contracting involves the active participation of the child throughout the development, implementation, and evaluation of the contract. For many children, contracting is a first experience in identifying specific ways they would like to act and then arranging certain aspects of their environment to set the occasion for and reward those acts. If more of the decision making for all parts of the contracting process is turned over to children gradually and systematically, they can become skilled at self-contracting. A **self-contract** is a contingency contract that a person makes with herself, incorporating a self-selected task and reward as well as personal monitoring of task completion and self-delivery of the reward. Self-contracting skills can be achieved by a multistep process of having an adult prescribe virtually all of the elements of the task and reward and gradually shifting the design of the elements to the child.

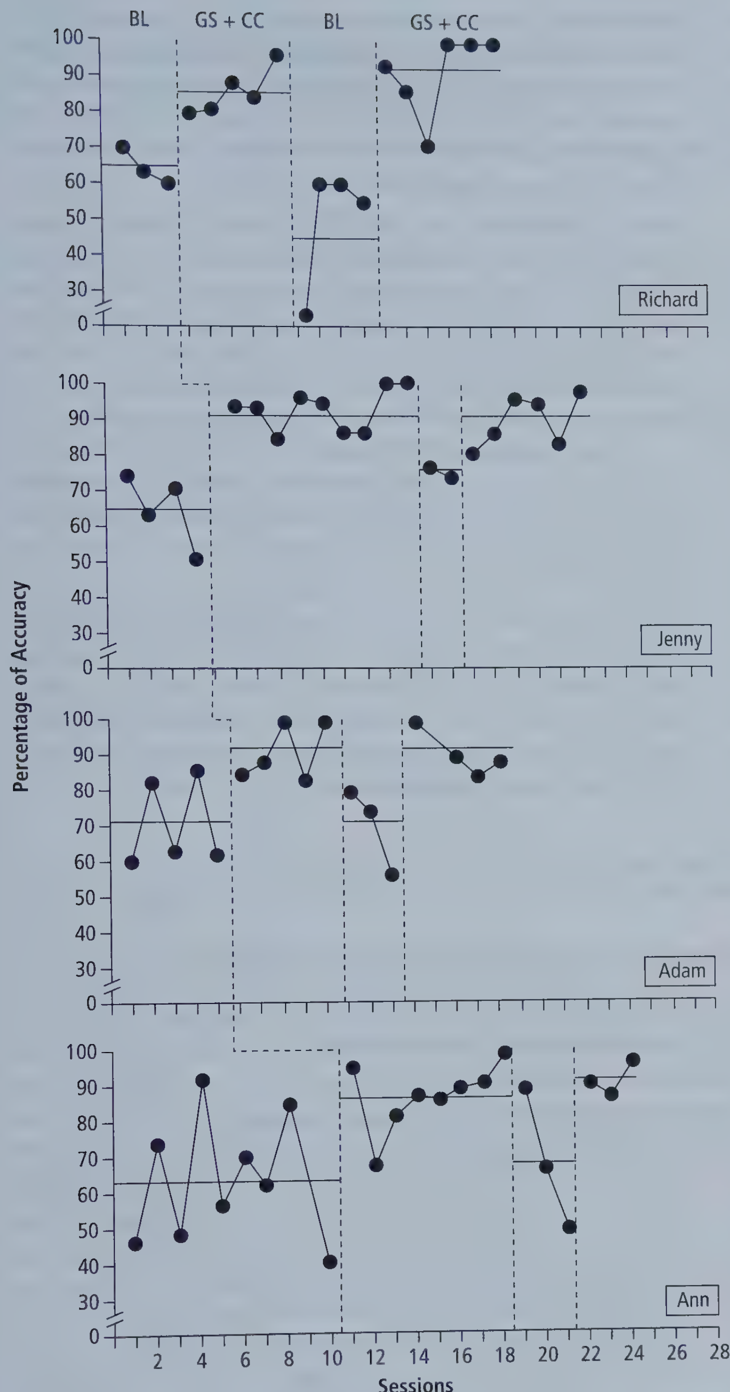

Figure 28.12 Percentage of homework problems completed accurately during baseline and a treatment condition consisting of goal setting and contingency contracting. Sessions correspond to sequential school days (i.e., Mondays through Thursdays) on which subjects were assigned homework. Data were not collected on days on which homework was not assigned.

From "The Use of Goal Setting and Contingency Contracting for Improving Children's Homework Performance" by D. L. Miller & M. L. Kelley, 1994, *Journal of Applied Behavior Analysis, 27*, p. 80. Reproduced with permission of John Wiley & Sons,Inc.

How Do Contracts Work?

At first glance the principle of behavior behind contingency contracts seems deceptively simple: A behavior is followed by a contingent reward—surely a case of positive reinforcement. Yet, in most contracts the reward, although contingent, is too delayed to reinforce task completion directly; and many successful contracts specify a reward that would not function as a reinforcer for the task even if it was presented immediately after the task completion. Further, behavioral contracting is not a single procedure with a single associated behavior and a single reinforcer. Contracting is more accurately conceptualized as an intervention package that combines several behavior principles and procedures.

So, how do contracts work? Several principles, procedures, and factors are likely to apply. Certainly, reinforcement is involved, but not in as simple or direct a fashion as it might seem at first. *Rule-governed behavior* is probably involved (Malott & Shane, 2014; Skinner, 1969; see Chapter 11). A contract describes a rule: A specified behavior will be followed by a specified (and reasonably immediate) consequence. The contract itself serves as a response prompt to perform the target behavior and enables the effective use of a consequence (e.g., going to the movies Saturday night), too delayed to reinforce certain behaviors (e.g., practicing the trumpet on Tuesday). Delayed consequences can help exert control over behaviors performed hours and even days before if they are associated with and linked

by verbal behavior to the rule (e.g., "I've just finished my trumpet practice—that's another checkmark toward the movies on Saturday") or to interim token reinforcers (e.g., the checkmark on the contract after practicing). The physical visibility of the contract may also function as a response prompt for escaping "guilt" (Malott & Shane, 2014).

Developing Contingency Contracts

Although teachers, therapists, or parents can unilaterally determine a contract for a child or client, contracting is usually more effective when all of the parties involved play an active role in developing the contract. Contract development involves the specification of tasks and rewards in a fashion agreeable and beneficial to each party. Dardig and Heward (2016) described a five-step procedure for identifying tasks and rewards that can be used by teachers and families.[2]

Step 1: Hold a meeting. To get the entire group (family or class) involved in the contracting process, a meeting should be held. At this meeting, members can discuss how contracts work, how they can help the group cooperate and get along better, and how contracts can help individuals meet personal goals. Parents or teachers should emphasize that they will participate in all of the steps leading up to and including implementation of contracts. It is important that children view contracting as a behavior-exchange process shared by all members of the group, not as something adults impose on them. The field-tested list-making procedures described in the following steps provide a simple and logical framework for the selection of tasks and rewards for family and classroom contracts. Most groups can complete the procedure within 1 to 2 hours.

Step 2: Complete List A. Each member completes three lists prior to the actual writing of the contract. List A (see Figure 28.13) is designed to help each member identify not only those tasks he can perform within the context of a contract, but also those tasks he already does to help the group. In this way, positive attention can be focused on appropriate behaviors that individual members are currently completing satisfactorily.

Each member should be given a copy of List A. Everyone should be careful to describe all tasks as specifically as possible. Then the completed lists can be put aside, and the group can proceed to the next step. If a member is unable to write, that person's list can be completed orally.

Step 3: Complete List B. List B (see Figure 28.14) is designed to help group members identify possible contract tasks for other group members and helpful behaviors currently being completed by those persons. List B can also identify areas where disagreement exists between group members as to whether certain tasks are actually being completed properly and regularly.

Each member should be given a copy of List B and asked to write his or her name in all three blanks at the top. These lists can then be passed around the table so that everyone has a chance to write at least one behavior on each side of everyone else's list. Everyone writes on every List B except his or her own, and each person should be required to write at least one positive behavior on everyone else's List B. After completion, these lists should be set aside before moving to the next step.

Step 4: Complete List C. List C (see Figure 28.15) is simply a sheet with numbered lines on which each group member identifies potential rewards he would like to earn by completing contracted tasks. Participants should list not only everyday favorite things and activities but also special items and activities they may have wanted for a long time. It is all right if two or more people indicate the same reward. After List C is completed, each person should collect his two other lists and read them carefully, talking over any misunderstood items.

Step 5: Write and Sign Contracts. The final step begins with choosing a task for each person's first contract. Discussion should move around the group, with members helping each other decide which task is the most important to start doing first. Everyone should write *who* is going to perform the task, exactly *what* the task is, *how well* and *when* it has to be done, and any possible exceptions. Each person should also look at List C and choose a reward that is neither excessive nor insignificant but is fair for the selected task. Each member should write *who* will control the reward, *what* the reward is, *when* it is to be given, and *how much* is to be given. Everyone in the group should write and sign one contract during the first meeting.

Contracting with Nonreaders

Reading ability by the participant is not a prerequisite for contingency contracting; however, the individual must be able to come under the control of the visual or oral statements (rules) of the contract. Contracting with nonreaders involves three types of clients: (a) preschoolers with good verbal skills, (b) school-aged children with limited reading skills, and (c) adults with adequate language and conceptual skills but who lack reading and writing skills. Contracts for nonreaders specify tasks and rewards with nonprint elements such as symbols, pictures, photos, and audio recordings chosen to suit the individual skills and preferences of children and adults in all three nonreader groups (see Figure 28.16).

Figure 28.16 A contingency contract for a nonreader.

Contracting with Nonsigners

Although some children are eager, and most at least willing, to try a contract, some want nothing to do with the whole idea. Using contingency contracting in a collaborative approach (Lassman, Jolivette, & Wehby, 1999) may reduce the likelihood of noncompliance, but a parent or practitioner should never try to force the child to sign a contract. Coercion is contrary to the whole idea of behavioral contracting. Instead of giving up, however, Dardig and Heward (2016) suggest the following strategies for working with a child who refuses to enter into a contingency contract:

- *Shaping and ignoring.* Remember the nonsigner's anti-contracting behavior is just that—*behavior*. Perhaps the worst thing parents can do when their child says "Contracts are stupid!" or "You'll never get me to sign a contract" is to argue or try to convince the child that contracts are "cool." Better instead to pay attention to the child when he makes any remotely positive or even neutral comments about contracting, such as, "I wonder if anyone has ever made a contract with his parents for _________."
- *Modeling.* In families with other children, perhaps the nonsigner's sibling will try contracting. In a two-parent family, the parents can do contracts with one another; a single parent might develop a contract with a friend as a way to demonstrate the idea. A nonsigner who observes his sibling(s) and/or parent(s) successfully using a contract may then be willing to give it a try.
- *Parent contract.* Past experience may lead children to be wary of what their parents have in store for them and to always believe they get the short end of the stick. The parent might say something like, "Okay, if you don't think contracts are fair (or whatever the nonsigner doesn't like about contracts), let's make the first contract be for my (our) behavior and you control the reward." After controlling the reward for a contract specifying a task his parent(s) must do, the nonsigner may learn that contracts can work, and may be willing to enter into a contract for his behavior.
- *Self-contract.* Perhaps the nonsigner does not trust that the contract will be honest, that he will complete the task but the reward will not be delivered. Allowing the child to control both the task and the reward components of a contract is one tactic for dealing with this suspicion. Will the child cheat if given such freedom? Perhaps the child will, but most will not. Some research shows that self-determined standards of task and reward result in better performance by children than do criteria set by adults (Dickerson & Creedon, 1981; Olympia, Sheridan, Jenson, & Andrews, 1994).

However, even after the best of positive approaches, the reality is that some nonsigners may not agree to participate in a contingency contract. In such cases, another behavior change strategy would be a better alternative for dealing with the target behavior.

Guidelines for Implementing and Evaluating Contracts

In determining whether contingency contracting is an appropriate intervention for a given problem, the practitioner should consider the nature of the desired behavior change, the verbal and conceptual skills of the participant, the individual's relationship with the person(s) with whom the contract will be made, and the available resources. The target behavior to be changed by a contingency contract should already be in the person's repertoire and under proper stimulus control in the settings where the response is desired. If the behavior is not in the individual's repertoire, other behavior-building techniques should be attempted (e.g., modeling, shaping, chaining). Contracting is most effective with behaviors that produce permanent products (e.g., completed homework assignment, cleaned bedroom) or that occur in the presence of the person who is to deliver the reward (e.g., the teacher or parent).

Numerous lists of rules and guidelines for effective contingency contracting have been published (e.g., Dardig & Heward, 2016; Downing, 1990; Homme, Csanyi, Gonzales, & Rechs, 1970). Table 28.3 provides a list of the frequently cited guidelines and rules.

The simplest way to evaluate a contract is to record the occurrence of task completion. Including a task record on the contract helps make evaluation a natural by-product of the contracting process. By comparing data from the task record with a precontract baseline of task completion, an objective determination can be made as to whether improvement has occurred. A good outcome is one that results in the specified task being completed more often than it was before the contract.

Sometimes the outcome data indicate that the task is being completed more often and more consistently than it was before the contract, but the parties involved are unsatisfied. In such cases, either the original problem or goal that prompted the development of the contract is not being attained, or one or more of the participants are unhappy with how the contract is being carried out. The first possibility results from selecting the wrong behavior for the task part of the contract. For example, suppose ninth-grader Lenwood wants to improve on the D's and F's he has been getting on his algebra assignments at school and writes a contract with his parents, specifying the task as "studying algebra for 1 hour each school night." After several weeks, Lenwood has studied algebra for the required 1 hour on all but two school nights, but his poor grades remain unchanged. Has Lenwood's contract worked? The correct answer is both yes and no. Lenwood's contract was successful in that he consistently completed the specified task—1 hour of study each school night. However, in terms of his original objective—earning better algebra grades—the contract was a failure. Lenwood's contract helped him change the behavior he specified, but he specified the wrong behavior. Studying for 1 hour, for Lenwood at least, was not directly related to his goal. By changing his contract to require that he solve correctly 10 algebra equations each night (the behavior required to get good grades on algebra tests), his goal of obtaining better grades may become a reality.

It is also important to consider the participant's reactions to the contract. A contract that produces desired change in the specified target behavior but causes other maladaptive or emotional responses may be an unacceptable solution. Having the client participate in the development of the contract and jointly conducting regular progress checks help to avoid this situation.

TABLE 28.3 Contingency Contracting Rules and Guidelines

Rules and Guidelines	Comments
Write a fair contract.	There must be a fair relationship between the difficulty of the task and the amount of the reward. The goal is to achieve a win–win situation for both parties, not for one party to gain an advantage over the other.
Write a clear contract.	In many instances, a contract's greatest advantage is that it specifies each person's expectations. When a teacher or parent's expectations are explicit, performance is more likely to improve. Contingency contracts must say what they mean and mean what they say.
Write an honest contract.	An honest contract exists if the reward is delivered at the time and in the amount specified when the task is completed as agreed. In an honest contract, the reward is *not* delivered if the task has not been completed as specified.
Build in several layers of rewards.	Contracts can include bonus rewards for beating the best daily, weekly, or monthly performance.
Consider a response cost contingency.	Occasionally, it may be necessary to incorporate a "fine"—the removal of rewards—if the agreed-upon task is not completed.
Post the contract in a visible place.	Public posting allows all parties to see progress toward achieving the goals of the contract.
Renegotiate and change a contract when either party is consistently unhappy with it.	Contracting is designed to be a positive experience for all parties, not a tedious endurance contest to determine survivors. If the contract is not working, reconsider the task, the reward components, or both.
Terminate a contingency contract.	A contingency contract is a means to an end, not the end product. Once independent and proficient performance is achieved, the contract can be terminated. Further, a contract can and should be terminated when one party or both parties consistently fail to meet the contract's terms.

SUMMARY

Token Economy

1. A token economy, also called a token reinforcement system, is a behavior change system consisting of three major components: (a) a specified list of target behaviors to be reinforced; (b) tokens or points that participants receive for emitting the target behaviors; and (c) a menu of items or activities, privileges, and backup reinforcers from which participants choose and obtain by exchanging tokens they have earned.

2. Tokens are objects, symbols, marks, or chips that function as generalized conditioned reinforcers because they have been paired with a wide variety of backup reinforcers.

3. As participants move "up" from one level to the next, they have access to more privileges and are expected to demonstrate more independence. A level system is a type of token economy in which participants move up or down a hierarchy of levels contingent on meeting specific performance criteria with respect to the target behaviors.

4. There are six basic steps in designing a token economy: (1) identifying the target behaviors and rules; (2) selecting the tokens that will serve as a medium of exchange; (3) selecting a menu of backup reinforcers; (4) establishing a token exchange ratio; (5) writing procedures to specify when and how tokens will be dispensed and exchanged and what will happen if the requirements to earn a token are not met; and (6) field-testing the system before full-scale implementation.

5. When establishing a token economy, decisions must be made regarding how to begin, conduct, maintain, remove, and evaluate the system.

Group Contingencies

6. In a group contingency a common consequence (usually, but not necessarily, a reward intended to function as reinforcement) is contingent on the behavior of one member of the group, the behavior of part of the group, or the behavior of everyone in the group.

7. Group contingencies can be classified as independent, dependent, and interdependent, and they offer the behavior analyst multiple advantages for improving or reducing behaviors.

8. Six guidelines can assist the practitioner in implementing a group contingency: (a) choose a powerful reward, (b) determine the behavior to change and any collateral behaviors that might be affected, (c) set appropriate performance criteria, (d) combine with other procedures when appropriate, (e) select the most appropriate group contingency, and (f) monitor individual and group performance.

9. Future applications of group contingencies might explore their effectiveness with larger societal issues (e.g., global warming), or chronic, systemic, difficult-to-treat individual challenges (e.g., smoking cessation, addictive behaviors).

Contingency Contracting

10. A contingency contract is a document that specifies a contingent relation between the completion of a target behavior and access to, or delivery of, a specified reward.

11. Two components required in all contingency contracts are a description of the task and a description of the reward. Under *task*, who, what, when, and how well should be specified. Under *reward*, who, what, when, and how much should be specified. An optional task record provides a place for recording the progress of the contract and providing interim rewards.

12. A self-contract is a contingency contract that an individual makes with herself, incorporating a self-selected task and reward as well as self-monitoring of task completion and self-delivery of the reward.

13. Contracts for nonreaders specify tasks and rewards with nonprint elements such as symbols, pictures, photos, and audio recordings.

KEY TERMS

backup reinforcer	group contingency	level system
behavioral contract	hero procedure	self-contract
contingency contract	independent group contingency	token
dependent group contingency	interdependent group contingency	token economy

MULTIPLE-CHOICE QUESTIONS

1. A description of the task should include which of the following when writing a contingency contract?
   a. A description of the reward
   b. A description of when the reward will be delivered
   c. A method of tracking progress
   d. A description of when the task should be performed
   Hint: (See "Contingency Contracting")

2. A contingency contract:
   a. Is a verbal agreement among two individuals
   b. Specifies how two people will behave toward each other
   c. Often causes scapegoating among learners and peers
   d. Depends largely on the use of punishment for its effectiveness
   Hint: (See "Contingency Contracting")

3. Reinforcers in a token economy might include:
   a. Naturally occurring activities such as classroom jobs, games, etc.
   b. Privileges
   c. Tangible items, such as candy, pencils, etc.
   d. All of these
   Hint: (See "Token Economy")

4. The primary reason one might consider using a level system with a token system is that:
   a. Doing so can foster self-management
   b. Doing so makes it easier to withdraw the token economy
   c. Level systems are more preferred for all learners
   d. Level systems are easier to manage
   Hint: (See "Token Economy")

5. Token economies often need to be:
   a. Complex
   b. Individualized
   c. Maintained forever
   d. All of these
   Hint: (See "Implementing a Token Economy")

6. When selecting backup reinforcers:
   a. Consider ethical and legal issues
   b. It is a good idea to use basic need items (e.g., lunch) as a reinforcer
   c. Keep the pool of backup reinforcers small
   d. Never use edibles
   Hint: (See "Implementing a Token Economy")

7. A teacher says to his class: "Melissa is working on remembering to follow instructions when I give them. Melissa is going to keep track of whether or not she follows my instructions. If she follows 90% of my instructions today (or better), our whole class will watch a movie at the end of the day." What type of group contingency is this?
   a. Independent
   b. Dependent
   c. Interdependent
   d. None of these
   Hint: (See "Group Contingencies")

8. Group contingencies can:
   a. Lighten the workload for the practitioner
   b. Save time
   c. Create problems with learners
   d. All of these
   Hint: (See "Group Contingencies")

9. How could a learner sabotage a group contingency?

a. By purposefully not meeting the performance criterion so that no one gets the reinforcer

b. By not showing up for school on a given day

c. By urging peers to participate in the program

d. By congratulating peers who are meeting the criterion

Hint: (See "Group Contingencies")

10. An interdependent group contingency is most useful if:

a. One wants to change the behavior of one person or a small group of individuals

b. One wants to differentially reinforce individuals for appropriate behavior

c. One wants to change everyone's performance

d. All of these

Hint: (See "Group Contingencies")

ESSAY-TYPE QUESTIONS

1. When describing the reward in a contingency contract, what are the four important things to include in the description?

Hint: (See "Contingency Contracting")

2. You are a consultant working with a family that wants to write a contingency contract with their children to have better behavior in the home. Describe the process you would ask the family to go through to develop the contract.

Hint: (See "Developing Contingency Contracts")

3. What are the main components of a token economy?

Hint: (See "Token Economy")

4. If you were going to implement a token economy, what would you use as a token? Why would you select this as a token? Make sure in your answer you discuss the important considerations one must make when selecting the token.

Hint: (See "Token Economy")

5. Identify and define the different types of group contingencies.

Hint: (See "Group Contingencies")

6. What are the six guidelines for implementing a group contingency?

Hint: (See "Guidelines for Implementing a Group Contingency")

NOTES

1. A total of 1500 steps was added, as researchers determined that this number of steps represented 15 to 20 minutes of at least moderate exercise per day.
2. Research and development of the *Sign Here* contracting method described here was informed by three doctoral dissertations at The Ohio State University. Kabler (1976) used *Sign Here* to teach contracting skills to three classes of fourth-grade students. Norman (1977) found that eight of nine parents of children exhibiting behavior problems at home wrote and implemented contracts that reduced disruptions in the home. Shrewsberry (1977) used *Sign Here* to teach contracting to parents from 59 families, who wrote and implemented 154 contracts during a 6-week period. The parents judged 138 (90%) of those contracts as successful in increasing their children's completion of the specified tasks.

CHAPTER 29

Self-Management

LEARNING OBJECTIVES

- Define self-management, its advantages and benefits, and specific types of self-management strategies.
- Define self-monitoring, list and discuss suggested guidelines or procedures for its use, and discuss various derivatives of self-monitoring.
- Compare and contrast different types of self-administered consequences.
- Define and discuss four additional types of self-management tactics.
- List and discuss various suggestions for conducting an effective self-management program.

Raylene often failed to do the things she needed and wanted to do. Her days were just so busy! But Raylene is beginning to get a handle on her hectic life. This morning a sticky-note on her closet door reminded her to wear her gray suit for her luncheon meeting. A note on the refrigerator prompted her to take her completed sales report to work. When Raylene got into her car—sales report in hand and looking sharp in her gray suit—and sat on the library book she'd placed on the driver's seat the night before, chances were good that she would return the book that day and avoid another overdue fine.

Daryl collected the last data point for his master's thesis nearly a year ago. It's a solid study on a topic he enjoys and believes important, but Daryl is struggling mightily to write his thesis. Daryl knows if he would sit down and write for an hour or two a day his thesis would get written. But the scope and difficulty of the task are daunting. Daryl wishes his ability to sit and write were half as well developed as his propensity for distraction.

Raylene recently discovered self-management—behaving in ways that alter the occurrence of other behaviors she wants to control—and feels on top of the world. Daryl sorely needs some self-management. This chapter defines self-management, identifies uses for self-management and the benefits of teaching and learning self-management skills, describes a variety of self-management strategies and tactics, and offers guidelines for designing and implementing successful self-management programs. We begin with a discussion of the role of the self as a controller of behavior.

THE "SELF" AS BEHAVIOR CONTROLLER

A fundamental precept of radical behaviorism is that the causes of behavior are found in the environment. Throughout the evolution of the human species, causal variables selected by the contingencies of survival have been transmitted through genetic endowment. Other causes of behavior are found in the contingencies of reinforcement that operate during the lifetime of an individual. What role, then, if any, is left for the *self* to play?

Locus of Control: Internal or External Causes of Behavior

Proximate causes of some behaviors are apparent by observing events as they unfold. A mother picks up and cuddles her crying infant, and the baby stops crying. A highway worker leaps off the road when a fast-approaching car nears. An angler casts his lure toward the spot where his previous cast produced a strike. A behavior analyst would likely suggest the involvement of escape, avoidance, and positive reinforcement contingencies, respectively, for these events. Although others might offer mentalistic explanations for why the person in each scenario responded as he or she did (e.g., the infant's crying triggered the mother's nurturing instinct), most people would identify the same antecedent events—a baby cried, a speeding car approached, a fish struck the lure—as functional variables in the three scenarios. An analysis of the three episodes would reveal almost certainly that the immediately preceding events had functional roles: the crying baby and speeding car as motivating operations that evoked escape and avoidance responses; the biting fish as a reinforcer that led to repeating the cast that produced it.

But much human behavior does not immediately follow such obviously related antecedent events. Nonetheless, we humans have a long history of assigning causal status to events that immediately precede behavior. As Skinner (1974) noted, "We tend to say, often rashly, that if one thing follows another, it was probably caused by it—following the ancient precept of *post hoc, ergo propter hoc* (after this, therefore because of this)" (p. 7). When causal variables are not readily apparent in the immediate environment, the tendency to point to internal causes of behavior is particularly strong. As Skinner explained:

> The person with whom we are most familiar is our self; many of the things we observe just before we behave occur

Figure 29.1 Examples of four target behaviors for self-management and the self-management behavior emitted to change each example.

Target Behavior	Self-Management Behavior
• Save money instead of spending it on frivolous items.	• Enroll in a payroll deduction plan.
• Take garbage and recycling cans from garage to the curb on Thursday nights for pickup early Friday morning.	• After backing the car out of the garage for work Thursday morning, pull the trash and recycling cans onto the space in the garage where you will park the car in the evening.
• Ride exercise bike for 30 minutes each evening.	• Make a chart of the minutes you ride, and show it to a coworker each morning.
• Write a 20-page term paper.	• (1) Outline paper and divide it into five 4-page parts; (2) specify a due date for each part; (3) give roommate five $10 checks made out to a despised organization; (4) on each due date show a completed part of the paper to roommate and get one $10 check back.

> within our body, and it is easy to take them as the causes of our behavior. . . . Feelings occur at just the right time to serve as causes of behavior, and they have been cited as such for centuries. We assume that other people feel as we feel when they behave as we behave. (pp. 7, 8)

Why does one college student maintain a regular study schedule from the first week of the semester while her roommates party night after night? When a group of people joins a weight loss or a smoking cessation program in which each member is exposed to the same intervention, why do some people meet their self-determined goals but others do not? Why does a high school basketball player with limited physical abilities consistently outperform his more athletically gifted teammates? The hardworking student is said to have more willpower than her less studious roommates; the group members who lost weight or stopped smoking are thought to possess more desire than their peers who failed to meet their goals or dropped out; the athlete's superior play is considered a result of his exceptional drive. Although some psychological theories grant causal status to hypothetical constructs such as *willpower, desire*, and *drive*, these explanatory fictions lead to circular reasoning, bring us no closer to understanding the behaviors they claim to explain, and thus have no role in a behavior analysis of self-control.[1]

Skinner's Two-response Conceptualization of Self-Control

Skinner was the first to apply the philosophy and theory of radical behaviorism to behavior typically considered controlled by the self. In his classic textbook, *Science and Human Behavior*, Skinner (1953) devoted a chapter to self-control.

> When a man controls himself, chooses a course of action, thinks out the solution to a problem, or strives toward an increase in self-knowledge, he is *behaving*. He controls himself precisely as he would control the behavior of anyone else—through the manipulation of variables of which behavior is a function. His behavior in so doing is a proper object of analysis, and eventually it must be accounted for with variables lying outside the individual himself. (pp. 228–229)

Skinner (1953) conceptualized **self-control [Skinner's analysis]** as a two-response phenomenon:

> One response, the *controlling response*, affects variables in such a way as to change the probability of the other, the *controlled response*. The controlling response may manipulate any of the variables of which the controlled response is a function; hence there are a good many different forms of self-control. (p. 231)

Skinner (1953) described a wide variety of self-control techniques, including use of physical restraint (e.g., clapping a hand over one's mouth to prevent yawning at an embarrassing moment), changing the antecedent stimulus (e.g., putting a box of candy out of sight to reduce overeating), and "doing something else" (e.g., talking about another topic to avoid talking about a particular topic), to name a few. Since Skinner's initial list of techniques, a variety of taxonomies of self-control tactics have been described (e.g., Kazdin, 2013; Watson & Tharp, 2014). All self-control—or self-management—tactics can be operationalized in terms of two behaviors: (a) the target behavior a person wants to change (Skinner's controlled response) and (b) the self-management behavior (Skinner's controlling response) emitted to change the target behavior. Consider the examples in Figure 29.1.

SELF-MANAGEMENT DEFINED

There is nothing mystical about self-management.[2] Self-management is behavior a person emits to influence another behavior. But many of the responses a person emits each day affect other behaviors. Putting toothpaste on a toothbrush makes it likely that tooth brushing will occur soon. But we do not consider squeezing toothpaste on a brush an act of "self-management" just because it evokes tooth brushing. What gives some responses the special status of self-management? How can we distinguish self-management from other behavior?

Numerous definitions of self-control or self-management have been proposed, many of which are similar to one offered by Thoresen and Mahoney (1974). They suggested that self-control occurs when, in the "relative absence" of immediate external

controls, a person emits a response designed to control another behavior. For example, a man shows self-control if, when home alone and otherwise free to do whatever he wants, he forgoes his usual peanuts and beer and rides his exercise bike for 30 minutes. According to definitions such as Thoresen and Mahoney's, the man would not be credited with self-control if his wife were there reminding him not to overeat, praising him for riding the exercise bike, and marking his time and mileage ridden on a chart.

What, however, if the man had asked his wife to prompt, praise, and chart his exercise? Would his having done so constitute a form of self-control? One problem with conceptualizing self-control as occurring only in the absence of "external control" is that it excludes those situations in which a person designs contingencies that entail external control for a behavior he desires to change. Another problem with the "relative absence of external controls" concept of self-control is that it creates a false distinction between internal and external controlling variables when, in fact, all causal variables for behavior ultimately reside in the environment.

Definitions of self-control such as Kazdin's (2013), "those behaviors that an individual deliberately undertakes to achieve self-selected outcomes by manipulating antecedent and consequence events" (p. 627), are more functional for applied behavior analysts. With this definition, self-control occurs whenever a person purposely emits behavior that changes the environment to modify another behavior. Self-control is considered *purposeful* in the sense that a person labels (or *tacts*) her responses as designed to attain a specified result (e.g., to reduce the number of cigarettes smoked each day).

We define **self-management** as the personal application of behavior change tactics that produces a desired improvement in behavior. This intentionally broad definition of self-management encompasses one-time self-management events, such as Raylene's taping a note to her closet door to remind herself to wear her gray suit the next day, as well as complex, long-running self-directed behavior change programs in which a person plans and implements one or more contingencies to change his behavior. It is also a functional definition in that the desired change in the target behavior must occur for self-management to be demonstrated.

Self-management is a relative concept. A behavior change program may entail a small degree of self-management or be totally conceived, designed, and implemented by the person. Self-management occurs on a continuum along which the person controls one or all components of a behavior change program. When a behavior change program is implemented by a person or team (e.g., therapist, parent, school staff) on behalf of another (e.g., client, child, student), the external change agent manipulates motivating operations, arranges discriminative stimuli, provides response prompts, delivers differential consequences, and observes and records the occurrence or nonoccurrence of the target behavior. Some degree of self-management is involved whenever a person performs (that is to say, controls) any element of a program that changes his behavior.

It is important to recognize that defining self-management as the personal application of behavior change tactics that results in a desired change in behavior does not explain the phenomenon. Our definition of self-management is descriptive only, and purposively broad. Although self-management tactics can be classified according to their emphasis on a given component of the three- or four-term contingency, or by their structural similarity with a particular principle of behavior (e.g., stimulus control, reinforcement), it is likely that all self-management tactics involve multiple principles of behavior. Thus, when researchers and practitioners describe self-management tactics, they should provide a detailed statement of the procedures used. Behavior analysts should not ascribe the effects of self-management interventions to specific principles of behavior in the absence of an experimental analysis demonstrating such relations. Only through such research will applied behavior analysis develop a more complete understanding of the mechanisms that account for the effectiveness of self-management.[3]

Terminology: Self-Management or Self-Control?

Although *self-management* and *self-control* often appear interchangeably in the behavioral literature, we recommend that *self-management* be used in reference to a person acting "in some way *in order to* change subsequent behavior" (Epstein, 1997, p. 547, emphasis in original). We make this recommendation for three reasons. First, *self-control* is an "inherently misleading" term that implies that the ultimate control of behavior lies within the person (Brigham, 1980). Although Skinner (1953) acknowledged a person could achieve practical control over a given behavior by acting in ways that manipulate variables influencing that behavior, he argued that the controlling behaviors themselves are learned from the person's interactions with the environment.

> A man may spend a great deal of time designing his own life—he may choose the circumstances in which he is to live with great care, and he may manipulate his daily environment on an extensive scale. Such activity appears to exemplify a high order of self-determination. But it is also behavior, and we account for it in terms of other variables in the environment and history of the individual. It is these variables which provide the ultimate control. (p. 240)

In other words, the causal factors for "self-control" (i.e., controlling behaviors) are to be found in a person's experiences with his environment. Beginning with the example of a person setting an alarm clock (controlling behavior) so as to get out of bed at a certain time (controlled behavior) and concluding with an impressive instance of self-control by the main character in Homer's *Odyssey*, Epstein (1997) described the origin of self-control as follows:

> As is true of all operants, any number of phenomena might have produced the [controlling] behavior originally: instructions, modeling, shaping, or generative process (Epstein, 1990, 1996), for example. Its occurrence might have been verbally mediated by a self-generated rule ("I'll bet I'd get up earlier if I set an alarm clock"), and that rule, in turn, might have had any number of origins. Odysseus had his men tie him to his mast (controlling behavior) to lower the probability that he would steer toward the Siren's song (controlled behavior). This was an elegant instance of self-control, but it was entirely instruction driven: Circe had told him to do it. (p. 547)

Second, attributing the cause of a given behavior to self-control can serve as an explanatory fiction. As Baum (2017) pointed out, *self-control* "seems to suggest controlling a [separate] self inside or [that there is] a self inside controlling external behavior. Behavior analysts reject such views as mentalistic. Instead they ask, 'What is the behavior that people call "self-control"?'" (p. 167, words in brackets added). Sometimes *self* is synonymous with *mind* and "not far from the ancient notion of homunculus—an inner person who behaves in precisely the ways necessary to explain the behavior of the outer person in whom he dwells" (Skinner, 1974, p. 121).[4]

Third, laypeople and behavior analysts alike often use *self-control* to refer to a person's ability to delay gratification. In operant terms, this definition of **self-control [as impulse control]** entails responding to achieve a delayed, but larger or higher quality, reinforcer instead of acting to obtain an immediate, less valuable, reinforcer (Rachlin & Greene, 1972; see Box 29.1). Using the same term to refer to a tactic for changing behavior and to a certain type of behavior that may be an outcome of that tactic is confusing and logically faulty. Restricting the use of *self-control* to describe a certain type of behavior (i.e., not acting impulsively) may reduce the confusion caused by using *self-control* as the name for both an independent variable and dependent variable. In this sense, self-control can be a possible goal or outcome of a behavior change program irrespective of whether that behavior is the product of an intervention implemented by an external agent or the subject. Thus, a person can use self-management to achieve, among other things, self-control.

BOX 29.1

Do You Want $10 Now or $100 Next Year?

One way that behavior analysts conceptualize self-control is based on what organisms do when offered choices between rewards of different value and when those rewards can be obtained. Given a choice between a small reward and a larger reward, humans and nonhuman laboratory animals will most often select the larger reward. Offered a choice between an immediate reward and a delayed reward of equal value, organisms tend to choose the immediate reward. Such simple decisions are easy to predict—who doesn't want rewards sooner and have more rather than less?—and require no self-control (Green & Estle, 2003; Odum, 2011).

But things get more difficult to predict, and typical of situations we humans face every day, when the choice is between a smaller, sooner reward (SSR) and a larger, later reward (LLR). In behavioral research, choosing the SSR (e.g., smoking a cigarette) over the LLR (e.g., better health in the future) is considered impulsive behavior. Forgoing the SSR to obtain an LLR reward is viewed as self-control (Ainslie, 1974; Rachlin & Green, 1972).

Delayed rewards, regardless of their significance and magnitude (e.g., enough money for a secure retirement), exert decreasing influence over choice-making behavior as a function of their temporal distance from present circumstances. Both humans and nonhuman laboratory animals discount the value of delayed rewards; the greater the delay to the reward, the greater the discount (i.e., the less value or influence the reward has on current behavior. Behavior analysts call this phenomenon **delay discounting** (or *temporal discounting*) (Odum, 2011; Madden & Johnson, 2010).

Children with attention-deficit hyperactivity disorder (ADHD; Neef et al., 2005), compulsive gamblers (Dixon, Marley, & Jacobs, 2003), heavy smokers (Bickel, Odum, & Madden, 1999), binge drinkers (Vuchinich & Simpson, 1998), people with obesity (Davis, Patte, Curtis, & Reid, 2010), and heroin addicts (Kirby, Petry, & Bickel, 1999) more steeply discount the value of delayed rewards than do comparison groups, suggesting increased likelihood of impulsiveness. Behavior analysts have researched three strategies for decreasing impulsivity: gradually increasing the delay to the LLR, engaging in intervening activities during the delay, and making a commitment response.

Progressive Delay

The progressive delay strategy, first developed to teach "self-control" to pigeons (Ferster, 1953; Mazur & Logue, 1978), essentially shapes preference for LLRs. Subjects initially choose between an SSR and LLR, with each reward available immediately (or after a brief and equal delay, such as a 2-sec delay). After the subject selects the LLR some criterion number of times, the choice trials are repeated with a slight delay to the LLR. The duration of delay to the LLR is gradually increased over sessions.

Schweitzer and Sulzer-Azaroff (1988) reported one of the first applied studies using the progressive delay technique. Subjects were six preschool children described as impulsive by their teachers. Preassessment confirmed the children consistently chose SSRs over LLRs. Following treatment, five of the children chose the LLR more often and three children consistently preferred the LLR at all delay intervals tested. Progressive delay training has reduced impulsive choices by children with ADHD (Neef, Bicard, & Endo, 2001; Neef, Mace, & Shade, 1993), children and adults with autism (Dixon & Cummings, 2001), and adults with developmental disabilities (Dixon & Holcomb, 2000).

Intervening Activities

Engaging in intervening activities during the LLR delay interval may increase self-control. Binder, Dixon, and Ghezzi (2000) required the three children with ADHD to engage in an intervening verbal activity during the delay to the LLR. Two conditions with intervening activities during the delay alternated in multielement fashion. In one condition, the children repeated aloud,

(*continued*)

BOX 29.1 (continued)

"If I wait a little longer, I will get the bigger one." In the other condition, the children named pictures of objects depicted on flash cards. All children exhibited self-control by selecting the delayed rewards during both intervening activity conditions.

A self-control training procedure combining progressive delay and intervening activities has also been evaluated (Dixon et al., 1998; Dixon, Rehfeldt, & Randich, 2003; Dunkel-Jackson, Dixon, & Szekely, 2016). In one study, three adults with autism spectrum disorder were asked, "Do you want a little [reinforcer] now or a lot of [reinforcer] after [doing measuring cups or handwriting]"? (Dunkel-Jackson et al., 2016, p. 707). The delay to the LLR, and thus the duration of task engagement required, was then progressively increased. All three participants chose to engage in the intervening target behavior and earn the LLR on 79%, 77%, and 92% of the intervention trials. This approach not only enhanced self-control—it also increased task engagement.

Commitment Response

Azrin and Powell (1968) conducted a study to limit chain smoking that featured a specially designed cigarette case that locked after the smoker removed a cigarette. By choosing to only smoke cigarettes taken from the case, a participant could not smoke another cigarette for a predetermined amount of time, which increased from 6 minutes to 65 minutes over the course of the study. Rachlin and Green (1972) suggested that a smoker's use of the locking case was a commitment response leading to self-control. Since the smoker is just about to have a cigarette, the value of a future cigarette is negligible, making it easy to shut the case and forgo the next cigarette for a period of time. Similarly, an employee's commitment response of enrolling in a payroll saving plan at the beginning of the month, when money from future paychecks is unavailable (i.e., at a discounted value), is easier than depositing money from a paycheck in hand into a savings account (behavior leading to LLR) instead of impulsively spending it on another dinner out and tickets to a concert (the SSR).

Rachlin (2016) distinguishes between hard commitments to future behavior (snapping shut the locking cigarette case) and soft commitments that create patterns of behavior over time that come into contact with temporally distant contingencies (e.g., I can smoke as many cigarettes as I want today, but I commit to smoking the same number of cigarettes for each of the next 6 days).

To learn more about the experimental analysis, implications, and potential applications of delay discounting, see Critchfield and Kollins (2001); Hursh, Madden, Spiga, DeLeon, and Francisco (2013); and Jacobs, Borrero, and Vollmer (2013).

APPLICATIONS, ADVANTAGES, AND BENEFITS OF SELF-MANAGEMENT

In this section, we identify four basic applications of self-management and describe numerous advantages and benefits that accrue to people who use self-management, practitioners who teach it others, and to society as a whole.

Self-Management Applications

Self-management can help a person be more effective and efficient in daily life, replace bad habits with good ones, accomplish difficult tasks, and achieve personal goals.

Living a More Effective and Efficient Daily Life

Raylene's writing notes to herself and placing her library book on her car seat are examples of self-management techniques for overcoming forgetfulness or lack of organization. Most people use simple self-management techniques, such as making a shopping list before going to the store or creating "to-do" lists, as ways to organize their day; but few probably consider such ordinary efforts to be "self-management." Although many of the most widely used self-management techniques can be considered common sense, people with an understanding of basic principles of behavior can use that knowledge to apply those commonsense techniques more systematically and consistently in their lives.

Breaking Bad Habits and Acquiring Good Ones

Many behaviors we want to do more (or less) often and know that we should do (or not do) are caught in reinforcement traps. Baum (2017) suggested that impulsiveness, bad habits, and procrastination are products of naturally existing *reinforcement traps* in which immediate but smaller consequences have greater influence on our behavior than more significant outcomes that are delayed. Baum gave this description of a reinforcement trap for smoking:

> Acting impulsively leads to a small but relatively immediate reinforcer. The short-term reinforcement for smoking . . . lies in the effects of nicotine and social reinforcers such as appearing grown-up or sophisticated. The trouble with impulsive behavior lies in long-term ill effects. Gradually, over months or years, the bad habit takes its toll in consequences such as cancer, heart disease, and emphysema.
>
> The alternative to impulsiveness, self-control, . . . refraining from smoking, . . . also leads to both short-term and long-term consequences. The short-term consequences are punishing but relatively minor and short-lived: withdrawal symptoms (e.g., headaches) and possibly social discomfort. In the long term, however, . . . refraining from smoking reduces the risk of cancer, heart disease, and emphysema; ultimately, it promotes health. (pp. 168–169)

Reinforcement traps are two-sided contingencies that promote bad habits while simultaneously working against the selection of behavior that is beneficial in the long term. Even though we may know the rules describing such contingencies, the rules are difficult to follow. Malott (1984) described weak rules as those with delayed, incremental, or unpredictable outcomes. An example of a weak rule is *I'd better not smoke or I might get cancer someday and die*. Even though the potential consequence—cancer and death—is a major one, it is far off in the future and not a sure thing even then, which severely limits its effectiveness as a behavioral consequence. So, the rule *don't smoke or you might get cancer* is hard to follow. The deleterious effect of any one cigarette is small, so small that it is not even noticed. Emphysema and lung cancer are likely years and thousands of cigarettes away. How can one more puff hurt?

Self-management provides one strategy for avoiding the deleterious effects of reinforcement traps. A person can use self-management tactics to arrange immediate consequences that will counteract the consequences currently maintaining the self-destructive behavior.

Accomplishing Difficult Tasks

Immediate outcomes that bring a person only infinitesimally closer to a significant, long-term outcome do not control behavior. Many self-management problems are the result of outcomes that are small, but of cumulative significance. Malott (2005a) argued that our behavior is controlled by the outcome of each individual response, not by the cumulative effect of a large number of responses.

> The *natural contingency* between a response and its outcome will be *ineffective* if the outcome of each individual response is too small or too improbable, even though the cumulative impact of those outcomes is significant. So, we have trouble managing our own behavior when each instance of that behavior has only an insignificant outcome, though the outcomes of many repetitions of that behavior will be highly significant. And we have little trouble managing our own behavior, when each instance of that behavior has a significant outcome, though that outcome might be greatly delayed.
>
> Most obese people in the United States know the rule describing that contingency: *If you repeatedly overeat, you will become overweight*. The problem is, knowing the overweight rule does not suppress this one instance of eating that delicious fudge sundae topped with the whipped cream and the maraschino cherry, because a single instance of eating this dessert will cause no significant harm, and will, indeed, taste great. Knowledge of this rule describing the natural contingency exerts little control over gluttony.
>
> But the outcome of our behavior also needs to be probable. Many people have trouble following the buckle-up rule, even though they might get in a serious auto accident as soon as they pull onto the street. Even though the delay between the failure to buckle up and the accident could be only a few seconds, they fail to buckle up because the probability of the accident is so low. However, if they were driving in a dangerous auto race or a dangerous stunt-driving demonstration, they would always buckle up, because the probability of a serious accident would be fairly high. (pp. 516–517)

Just as a person who smokes just one more cigarette or eats another hot fudge sundae cannot detect that lung cancer or obesity is a noticeably closer outcome, graduate student Daryl does not perceive that writing one more sentence brings him closer to his goal of a completed master's thesis. Daryl is capable of writing one more sentence but he often has trouble getting started and working steadily on difficult tasks in which each response produces little or no apparent change in the size of the remaining task. So, he procrastinates.

Applying self-management to this type of performance problem involves designing and implementing one or more contrived contingencies to compete with the ineffective natural contingencies. The self-management contingency provides immediate consequences or short-term outcomes for each response or small series of responses. These contrived consequences increase the occurrence of the target responses, which over time produce the cumulative effects necessary to complete the task.

Achieving Personal Goals

People can use self-management to achieve personal goals, such as learning to play a musical instrument, learning a foreign language, running a marathon, sticking to a schedule of daily yoga sessions (Hammer-Kehoe, 2012), or simply taking some time each day to relax (Harrell, 2012) or listen to enjoyable music (Dams, 2012). For example, a graduate student who wanted to become a better guitarist used self-management to increase the time he practiced scales and chords (Rohn, 2002). He paid a $1 fine to a friend for each day that he failed to practice playing scales and chords for a criterion number of minutes before going to bed. Rohn's self-management program also included several contingencies based on the Premack principle (see Chapter 11). For example, if he practiced scales (ordinarily a low-rate behavior) for 10 minutes, he could play a song (a high-rate behavior).

Advantages and Benefits of Self-Management

A dozen potential advantages and benefits accrue to people who use self-management tactics and to practitioners who teach self-management skills to their clients and students.

Self-Management Can Influence Behaviors Not Accessible to External Change Agents

Self-management can be used to change behaviors that are inaccessible to observation by others. Behaviors such as thoughts of self-doubt, obsessive thoughts, and feelings of depression are private events for which a self-managed treatment approach may be needed (e.g., Kostewicz, Kubina, & Cooper, 2000; Kubina, Haertel, & Cooper, 1994).

Even publicly observable target behaviors are not always emitted in settings and situations accessible to an external change agent. The behavior a person wishes to change may need to be prompted, monitored, evaluated, or reinforced or punished on a day-to-day or even minute-to-minute basis in all of the situations and environments that the person encounters. Most successful smoking, weight loss, exercise, and habit-reversal programs, while planned and directed by others, rely heavily on participants using various self-management techniques while away from the treatment setting. Many behavior change goals brought to clinicians pose the same challenge: How can an effective contingency be arranged that follows the client at all times wherever she goes? For example, target behaviors designed to increase an employee's self-esteem and assertiveness can be identified and practiced in the therapist's office, but implementation of an active contingency in the workplace is apt to require self-management techniques.

External Change Agents Often Miss Important Instances of Behavior

In most education and treatment settings, particularly large-group situations, many important responses go unnoticed by the person responsible for applying behavior change procedures. Classrooms, for example, are especially busy places where desired behaviors by students often go unnoticed because the teacher is engaged with other tasks and students. As a result, students miss opportunities to respond, or they respond and receive no feedback because, in a behavioral sense, the teacher is not there. However, students who have been taught to evaluate their own performance and provide their own feedback in the form of self-delivered rewards and error correction, including seeking assistance and praise from their teacher when needed (e.g., Alber & Heward, 2000; Rouse, Everhart-Sherwood, & Alber-Morgan, 2014), are not dependent on the teacher's direction and feedback for every learning task.

Self-Management Can Promote the Generalization and Maintenance of Behavior Change

A behavior change that (a) continues after treatment has ended, (b) occurs in relevant settings or situations other than the one(s) in which it was learned originally, or (c) spreads to other related behaviors has generality (Baer, Wolf, & Risley, 1968). Important behavior changes without such generalized outcomes must be supported indefinitely by continued treatment.[5] When the student or client is no longer in the setting in which a behavior change was acquired, she may no longer emit the desired response. Particular aspects of the original treatment environment, including the person (teacher, therapist, parent) who administered the behavior change program, may have become discriminative stimuli for the newly learned behavior, enabling the learner to discriminate the presence or absence of certain contingencies across settings. Generalization to nontreatment environments is also hampered when the naturally existing contingencies in those settings do not reinforce the target behavior.

Self-management may overcome challenges to achieving generalized outcomes. Baer and Fowler (1984) posed and answered a pragmatic question related to the problem of promoting the generalization and maintenance of newly learned skills.

> What behavior change agent can go with the student to every necessary lesson, at all times, to prompt and reinforce every desirable form of the behavior called for by the curriculum? The student's own "self" can always meet these specifications. (p. 148)

A Small Repertoire of Self-Management Skills Can Control Many Behaviors

A person who learns a few self-management tactics can control a potentially wide range of behaviors. For example, self-monitoring—observing and recording one's own behavior—has been used to increase on-task behavior (Clemons, Mason, Garrison-Kane, & Wills, 2016), academic productivity and accuracy (e.g., Rock, 2005), homework completion and accuracy (Falkenberg & Barbetta, 2013), productivity at work (e.g., Christian & Poling, 1997), physical activity (Hayes & Van Camp, 2015), and reciprocal social conversations (Koegel, Park, & Koegel, 2014), and to decrease target behaviors such as cigarette smoking (Foxx & Brown, 1979) and stereotypy or tics (Crutchfield, Mason, Chambers, Wills, & Mason, 2015; Fritz, Iwata, Rolider, Camp, & Neidert, 2012; Tiger, Fisher, & Bouxsein, 2009).

People with Diverse Abilities Can Learn Self-Management Skills

People of wide-ranging ages and cognitive abilities have used self-management tactics successfully. Preschoolers (e.g., Sainato, Strain, Lefebvre, & Rapp, 1990), typically developing students from primary grades through high school (Busacca, Moore, & Anderson, 2015), students with learning disabilities (McDougall et al., 2017), students with emotional and behavior disorders (Bruhn, McDonald, & Kreigh, 2015), children with autism (Carr, Moore, & Anderson, 2014; Southall & Gast, 2011), and children and adults with intellectual and developmental disabilities (Grossi & Heward, 1998; Reynolds, Gast, & Luscre, 2014) have all used self-management successfully. Even college professors are capable of improving their performance with self-management (Malott, 2005a)!

Some People Perform Better Under Self-Selected Tasks and Performance Criteria

Participants in some studies have performed better with self-selected work tasks and consequences than under contingencies determined by others (e.g., Baer, Tishelman, Degler, Osnes, & Stokes, 1992; Olympia, Sheridan, Jenson, & Andrews, 1994; Parsons, Reid, Reynolds, & Bumgarner, 1990). For example, in three brief experiments with a single student, Lovitt and Curtiss (1969) found pupil-selected rewards and contingencies to be more effective than teacher-selected performance standards. In the first phase of Experiment 1, the subject, a 12-year-old boy in a special education classroom, earned a teacher-specified number of minutes of free time based on the number of math and reading tasks he completed correctly. In the next phase of the study, the student was allowed to specify

the number of correct math and reading items needed to earn each minute of free time. During the final phase of the study, the original teacher-specified ratios of academic production to reinforcement were again in effect. The student's median academic response rate during the self-selected contingency phase was 2.5 correct responses per minute (math and reading tasks reported together), compared to correct rates of 1.65 and 1.9 in the two teacher-selected phases.

An experiment by Dickerson and Creedon (1981) used a yoked-control (Sidman, 1960) and between-group comparison experimental design with 30 second- and third-graders and found that pupil-selected standards resulted in significantly higher academic production of both reading and math tasks. Both the Lovitt and Curtiss (1969) and the Dickerson and Creedon studies demonstrated that self-selected reinforcement contingencies *can* be more effective than teacher-selected contingencies. However, research in this area also shows that simply letting children determine their own performance standards does not guarantee high levels of performance; some studies have found that children select too-lenient standards when given the opportunity (Felixbrod & O'Leary, 1973, 1974). But interestingly, in a study of student-managed homework teams by Olympia and colleagues (1994), although students assigned to teams who could select their own performance goals chose more lenient accuracy criteria than the 90% accuracy criterion required of students on the teams that worked toward teacher-selected goals, the overall performance of the teams with student-selected goals was slightly higher than that of the teams working toward teacher-selected goals. More research is needed to determine the conditions under which students will self-select and maintain appropriate standards of performance.

People with Good Self-Management Skills Contribute to Efficient and Effective Group Environments

The overall effectiveness and efficiency of any group of people who share a working environment is limited when a single person is responsible for monitoring, supervising, and providing feedback for everyone's performance. Use of self-management skills by students, teammates, band members, or employees without having to rely on teachers, coaches, band directors, or managers for every task, improves the overall performance of the entire group. In the classroom, for example, teachers traditionally assume full responsibility for setting performance criteria and goals for students, evaluating students' work, delivering consequences for those performances, and managing students' social behavior. The time required for these functions is considerable. Students who can self-score their work, provide their own feedback using answer keys or self-checking materials (Bennett & Cavanaugh, 1998; Goddard & Heron, 1998), and behave appropriately without teacher supervision enable their teacher to attend to other aspects of the curriculum and perform other instructional duties (Mitchem, Young, West, & Benyo, 2001; Saddler & Good, 2006).

When Hall, Delquadri, and Harris (1977) conducted observations of elementary classrooms and found low levels of active student response, they surmised that higher rates of academic productivity might actually be punishing to teachers. Even though considerable evidence links high rates of student responding with academic achievement (e.g., Hattie, 2009; MacSuga-Gage & Simonsen, 2015), generating more student responses in most classrooms results in the teacher grading more papers. The time savings produced by students with even the simplest self-management skills can be significant. In one study, a class of five elementary special education students completed as many arithmetic problems as they could during a 20-min session each day (Hundert & Batstone, 1978). When the teacher graded the papers, an average of 50.5 minutes was required to prepare and conduct the session and to score and record each student's performance. When the students scored their own papers, the total teacher time needed to conduct the arithmetic period averaged 33.4 minutes.

Teaching Students Self-Management Skills Provides Meaningful Practice in Other Curriculum Areas

When students learn to define and measure behavior and to graph, evaluate, and analyze their own responses, they practice various math and science skills in a relevant way. When students are taught how to conduct self-experiments such as using A-B designs to evaluate their self-management projects, they receive meaningful practice in logical thinking and scientific methodology (Marshall & Heward, 1979; Moxley, 1998).

Self-Management Is an Ultimate Goal of Education

When asked to identify what education should accomplish for its students, most people—educators and laypeople alike—include in their reply the development of independent, self-directed citizens capable of behaving appropriately and constructively without the supervision of others. John Dewey (1939), one of America's most influential educational philosophers, said, "the ideal aim of education is the creation of self-control" (p. 75). A student's ability to be self-directed, with the teacher as a guide or facilitator, and his ability to evaluate his own performance have long been considered cornerstones of humanistic education.

As Lovitt (1973) observed, the fact that systematic instruction of self-management skills is *not* a regular part of most schools' curricula is a paradox because "one of the expressed objectives of the educational system is to create individuals who are self-reliant and independent" (p. 139). Although self-control is expected and valued by society, it is seldom addressed directly by the school curriculum. Teaching self-management as an integral part of the curriculum requires that students learn a fairly sophisticated sequence of skills (e.g., Marshall & Heward, 1979; McConnell, 1999). However, systematic teaching of self-management skills, if successful, is well worth the effort required; students will have an effective means of dealing with situations in which there is little, if any, external control.

Self-Management Benefits Society

Self-management serves two important functions for society (Epstein, 1997). First, citizens with self-management skills are more likely to fulfill their potential and make greater contributions to society. Second, self-management helps people behave

in ways (e.g., purchasing fuel-efficient automobiles, taking public transportation) that forgo immediate reinforcers that are correlated with devastating outcomes so long deferred that only future generations will experience them (e.g., depletion of natural resources and climate change). People who have learned self-management techniques that help them save resources, recycle, and burn less fossil fuel help create a better world for everyone. Self-management skills can provide people with the means of meeting the well-intentioned but difficult-to-follow rule, *Think globally but act locally*.

Self-Management Helps a Person Feel Free

Baum (2017) noted that people caught in reinforcement traps who recognize the contingency between their addictive behavior, impulsiveness, or procrastination and the eventual consequence that is likely to occur as a result of that behavior are unhappy and do not feel free. However, "Someone who escapes from a reinforcement trap, like someone who escapes from coercion, feels free and happy. Ask anyone who has kicked an addiction" (p. 193).

Ironically, a person who skillfully uses self-management techniques derived from a scientific analysis of behavior–environment relations predicated on an assumption of determinism is more likely to feel free than is a person who believes that her behavior is a product of free will. In discussing the apparent disconnect between philosophical determinism and self-control, Epstein (1997) compared two people: one who has no self-management skills and one who is very skilled at managing his own affairs.

> First, consider the individual who has no self-control. In Skinner's view, such a person falls prey to all immediate stimuli, even those that are linked to delayed punishment. Seeing a chocolate cake, she eats it. Handed a cigarette, she smokes it. . . . She may make plans, but she has no ability to carry them out, because she is entirely at the mercy of proximal events. She is like a sailboat blowing uncontrollably in a gale . . .
>
> At the other extreme, we have a skillful self-manager. He, too, sets goals, but he has ample ability to meet them. He has skills to set dangerous reinforcers aside. He identifies conditions that affect his behavior and alters them to suit him. He takes temporally remote possibilities into account in setting his priorities. The wind is blowing, but he sets the boat's destination and directs it there.
>
> These two individuals are profoundly different. The first is being controlled in almost a linear fashion by her immediate environment. The second is, in a nontrivial sense, controlling his own life. . . .
>
> The woman who lacks self-control skills *feels controlled*. She may believe in free will (in fact, in our culture, it's a safe bet that she does) but her own life is out of control. A belief in free will only exacerbates her frustration. She should be able to *will* herself out of any jam, but "willpower" proves to be highly unreliable. In contrast, the self-manager feels that *he is in control*. Ironically, like Skinner, he may believe in determinism, but he not only feels that he is in control, he is in fact exercising considerably more control over his life than our impulsive subject. (p. 560, emphasis in original)

Self-Management Feels Good

A final, but by no means trivial, reason for learning self-management is that being in control of one's life feels good. A person who arranges her environment in purposeful ways that support and maintain desirable behaviors not only will be more productive than she would otherwise be but also will feel good about herself. Seymour (2002) noted her personal feelings about a self-management intervention she implemented with the objective of running for 30 minutes 3 times per week.

> The guilt I had been feeling for the $2\frac{1}{2}$ past years had been burning strong within me. [As a former scholarship softball player] I used to exercise 3 hours per day (6 days per week) because that exercise paid for my schooling. . . . But now the contingencies were missing, and my exercising had gone completely down the tubes. Since the start of my project, I've run 15 out of the 21 times; so I've gone from 0% during baseline to 71% during my intervention. I'm happy with that. Because the intervention's successful, the guilt I have felt for the past years has been lifted. I have more energy and my body feels new and strong. It's amazing what a few contingencies can do to improve the quality of life in a big way. (pp. 7–12)

ANTECEDENT-BASED SELF-MANAGEMENT TACTICS

In this and the three sections that follow, we describe some of the many self-management tactics that behavioral researchers and clinicians have developed. Although no standard set of labels or classification scheme for self-management tactics has emerged, the techniques are often presented according to their relative emphasis on antecedents or consequences for the target behavior. An antecedent-based self-management tactic features the manipulation of events or stimuli antecedent to the target (controlled) behavior. Sometimes grouped under general terms such as *environmental planning* (Bellack & Hersen, 1977; Thoresen & Mahoney, 1974) or *situational inducement* (Martin & Pear, 2015), antecedent-based approaches to self-management encompass a wide range of tactics, including the following:

- Manipulating motivating operations to make a desired (or undesired) behavior more (or less) likely.
- Providing response prompts.
- Performing the initial steps of a behavior chain to ensure being confronted later with a discriminative stimulus that will evoke the desired behavior.
- Removing the materials required for an undesired behavior.
- Limiting an undesired behavior to restricted stimulus conditions.
- Dedicating a specific environment for a desired behavior.

Manipulate Motivating Operations

A motivating operation (MO) is an environmental condition or event that (a) alters the effectiveness of some stimulus, object, or event as a reinforcer and (b) alters the current rate of all behaviors that have been reinforced by that stimulus, object, or event in the past (see Chapter 16). An MO that increases the effectiveness of a reinforcer and has an evocative effect on behaviors that have produced that reinforcer is called an *establishing operation* (EO); an MO that decreases the effectiveness of a reinforcer and has an abative (i.e., weakening) effect on behaviors that have produced that reinforcer is called an *abolishing operation* (AO).[6]

The general strategy for incorporating an MO into a self-management intervention is to behave in a way (controlling behavior) that creates a certain state of motivation that, in turn, increases (or decreases, as desired) subsequent occurrences of the target behavior (controlled behavior). Imagine you have been invited to dinner at the house of someone known to be a first-rate cook. You want to obtain maximum enjoyment from what promises to be a special meal but are worried you will not be able to eat everything. Skipping lunch (controlling behavior) creates an EO that would increase the likelihood of your being able to enjoy the evening meal from appetizer through dessert (controlled behavior). Conversely, eating a meal just before going grocery shopping (controlling behavior) could serve as an AO that decreases the momentary value of ready-to-eat foods with high sugar and fat content as reinforcers and results in purchasing fewer such items at the supermarket (controlled behavior).

Provide Response Prompts

Creating stimuli that later function as extra cues and reminders for desired behavior is a simple and often effective self-management technique. Response prompts can take a wide variety of forms (e.g., visual, auditory, textual, symbolic), be permanent for regularly occurring events (e.g., entering "Put trash out tonight!" each Thursday on one's calendar), or be one-time affairs, as when Raylene wrote, "gray suit today" on a sticky-note and attached it to her closet door where she was sure to see it when dressing for work in the morning. Dieters often put pictures of overweight people, or perhaps even unattractive pictures of themselves, on the refrigerator door, near the ice cream, in the cupboard—anyplace where they might look for food. Seeing the pictures may evoke other controlling responses, such as moving away from the food, phoning a friend, going for a walk, or marking a point on an "I Didn't Eat It!" chart.

The same object can be used as a generic response prompt for various behaviors, such as putting a rubber band around the wrist as a reminder to do a certain task at some later time. This form of response prompt, however, will be ineffective if the person is unable later to remember what specific task the physical cue was intended to prompt. Engaging in some self-instruction when "putting on" a generic response prompt may help the person recall the task to be completed when seeing the cue later. For example, one of the authors of this text uses a small carabiner he calls a "memor-ring" as a generic response prompt. When the thought of an important task that can only be completed in another setting later in the day occurs to him, he clips the carabiner to a belt loop or the handle of his briefcase and "activates the memor-ring" by stating the target task to himself 3 times (e.g., "borrow Nancy's journal at Arps Hall," "borrow Nancy's journal at Arps Hall," "borrow Nancy's journal at Arps Hall"). When he sees the "memor-ring" in the relevant setting later, it usually functions as an effective prompt for completing the targeted task.

Self-arranged cues can also be used to prompt the occurrence of a behavior the person wants to repeat in a variety of settings and situations. In this case, the person might seed his environment with supplemental response prompts. For example, a father who wants to increase the number of times he interacts with and praises his children might place colorful sticky-notes printed with the word ZAP! (see Figure 29.2) in various

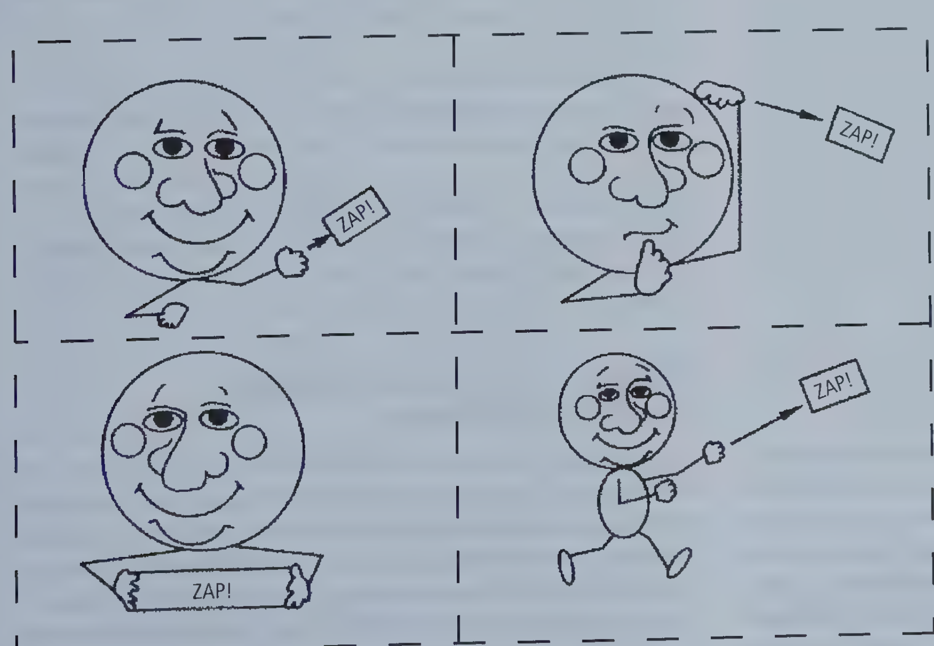

Figure 29.2 Contrived cues used by parents to prompt self-selected parenting behaviors.

Originally developed by Charles Novak. From *Working with Parents of Handicapped Children*, by W. L. Heward, J. C. Dardig, and A. Rossett, 1979, p. 26, Columbus, OH: Charles E. Merrill.

places around the house where he will see them routinely—on the microwave, on the TV remote control, as a bookmark. Each time he sees a ZAP! cue, the father is reminded to make a comment or ask a question of his child, or to look for some positive behavior for which he can provide attention and praise.

Smartphones, tablets, watches, and other portable digital devices can provide self-delivered audio and visual response prompts wherever target behavior should be emitted (Cullen & Alber-Morgan, 2015; Mechling, 2011). Individuals with autism and other disabilities have used digital devices to prompt acquisition and continued performance across a wide range of daily-living (Cannella-Malone, Brooks, & Tullis, 2013; Cannella-Malone, Chan, & Jimenez, 2017) and vocational tasks (Cullen, Alber-Morgan, Simmons-Reed, & Izzo, 2017).

Perform the Initial Steps of a Behavior Chain

Another self-management tactic featuring manipulation of antecedent events involves behaving in a manner that ensures your future behavior contacts a discriminative stimulus (S^D) that reliably evokes the target behavior. Although operant behavior is selected and maintained by its consequences, the moment-to-moment occurrence of many behaviors is influenced by the presence or absence of discriminative stimuli.

Many tasks consist of response chains. Each response in a chain produces a change in the environment that serves both as a conditioned reinforcer for the response that preceded it and as an S^D for the next response in the chain (see Chapter 23). Successful completion of a behavior chain requires each component response to be evoked by its related S^D. By performing part of a behavioral chain (the self-management response) at one point in time, a person changes her environment so that she will be confronted later with an S^D that will evoke the next response in the chain and will lead to the completion of the task (the self-managed response). Skinner (1983b) provided an excellent example of this tactic.

> Ten minutes before you leave your house for the day you hear a weather report: It will probably rain before you return. It occurs to you to take an umbrella (the sentence means quite literally what it says: The behavior of taking an umbrella occurs to you), but you are not yet able to execute it. Ten minutes later you leave without the umbrella. You can solve that kind of problem by executing as much of the behavior as possible when it occurs to you. Hang the umbrella on the doorknob, or put it through the handle of your briefcase, or in some other way start the process of taking it with you. (p. 240)

Remove Items Necessary for an Undesired Behavior

Altering the environment to make an undesired behavior less likely or, better yet, impossible to emit is another antecedent-based self-management tactic. The smoker who discards her cigarettes and the dieter who removes all cookies and chips from his house, car, and office, have, for the moment at least, effectively controlled their smoking and junk food eating. Although other self-management efforts will probably be needed to refrain from seeking and obtaining the harmful material, ridding oneself of the items needed to engage in an undesired behavior is a good start.

Limit Undesired Behavior to Restricted Stimulus Conditions

A person may be able to decrease an undesired behavior by limiting the setting or stimulus conditions where he engages in the behavior. To the extent that the restricted situation acquires stimulus control over the target behavior and access to the situation is infrequent or otherwise not reinforcing, the target behavior will occur less frequently. Imagine a man who habitually touches and scratches his face (he is aware of this bad habit because his wife often nags him about it and asks him to stop). In an effort to decrease his face touching, the man decides that he will do two things. First, whenever he becomes aware that he is engaging in face touching, he will stop; second, at any time he can go to a bathroom and touch and rub his face for as long as he wants.

Nolan (1968) reported the case of a woman who used restricted stimulus conditions in an effort to quit smoking. The woman noted she most often smoked when other people were around or when she watched television, read, or lay down to relax. It was decided she would smoke only in a prescribed place, and she would eliminate from that place the potentially reinforcing effects of other activities. She designated a specific chair as her "smoking chair" and positioned the chair so she could not watch TV or easily engage in conversation while sitting in it. She asked family members not to approach her or talk to her while she was in her smoking chair. She followed the procedure faithfully, and her smoking decreased from a baseline average of 30 cigarettes per day to 12 cigarettes per day. Nine days after beginning the program, the woman decided to try to reduce her smoking even further by making her smoking chair less accessible. She put the chair in the basement, and her smoking decreased to five cigarettes per day. A month after beginning the smoking chair program, the woman had quit smoking completely.

Goldiamond (1965) used a similar tactic to help a man who continually sulked when interacting with his wife. The husband was instructed to limit his sulking behavior to his "sulking stool," which was placed in the garage. The man went to the garage whenever he felt like sulking, sat on his stool and sulked for as long as he wanted, and left when he was finished sulking. The man found that his sulking decreased considerably when he had to sit on a stool in the garage to do it.

Dedicate a Specific Environment for a Desired Behavior

A person may achieve some degree of stimulus control over a behavior that requires diligence and concentration by reserving or creating an environment where he will only engage in that behavior. Students have improved their study habits and professors their scholarly productivity when they have selected a specific place in which to study, free of other distractions, and have not engaged in any other behaviors, such as daydreaming

or letter writing, in that place (Goldiamond, 1965). Skinner (1981b) suggested this kind of stimulus control strategy when he offered the following advice to aspiring writers:

> Equally important are the conditions in which the behavior occurs. A convenient place is important. It should have all the facilities needed for the execution of writing. Pens, typewriters, recorders, files, books, a comfortable desk and chair. . . . Since the place is to take control of a particular kind of behavior, you should do nothing else there at any time. (p. 2)

People who do not have the luxury of devoting a certain environment to a single activity can contrive a special stimulus that can be turned on and off in the multipurpose setting, as in this example provided by Watson and Tharp (2014):

> A man had in his room only one table, which he had to use for a variety of activities, such as writing letters, paying bills, watching TV, and eating. But when he wanted to do concentrated studying or writing, he always pulled his table away from the wall and sat on the other side of it. In that way, sitting on the other side of his table became the cue associated only with concentrated intellectual work. (p. 168)

Most students have a personal computer they use for their academic work but also for writing and reading personal e-mails, conducting family business, browsing the Internet, playing games, shopping online, and so on. In a manner similar to the man who sat on the other side of his table when studying and writing, a student might display a particular background on the computer's desktop that signals that only academic work is to be done on the computer. For example, when he sits down to study or write, a student could replace the standard display on his computer desktop, a photo of his dog, let's say, with a solid green background. The green desktop signals that only scholarly work will be done. Over time the "scholarly work" desktop may acquire a degree of stimulus control over the desired behavior. If the student wants to quit working and use the computer for something else, he must first change the background on the desktop. Doing so before he has fulfilled his time or productivity goal for a work session may generate some guilt that can be escaped by returning to work.

This tactic can also be used to increase a desired behavior that is not being emitted at an acceptable rate because of competing undesired behaviors. In one case, an adult with insomnia reportedly went to bed about midnight but did not fall asleep until 3:00 or 4:00 AM. Instead of falling asleep, the man would worry about mundane problems and turn on the television. Treatment consisted of instructing the man to go to bed when he felt tired, but he was not to stay in bed if he was unable to sleep. If he wanted to think about his problems or watch television, he could do so, but he was to get out of bed and go into another room. When he once more felt sleepy, he was to return to bed and try again to go to sleep. If he still could not sleep, he was to leave the bedroom again. The man reported getting up 4 or 5 times a night for the first few days of the program, but within 2 weeks he went to bed, stayed there, and fell asleep.

SELF-MONITORING

Self-monitoring has been the subject of more research and clinical applications than any other self-management strategy. **Self-monitoring** (also called *self-recording* or *self-observation*) is a procedure whereby a person systematically observes his behavior and records the occurrence or nonoccurrence of a target behavior. Originally conceived as a clinical assessment technique for collecting data on behaviors that only clients could observe and record (e.g., eating, smoking, fingernail biting), self-monitoring became a major therapeutic intervention in its own right because of the reactive effects it often produced. As discussed in Chapters 3 and 4, *reactivity* refers to the effects an assessment or measurement procedure has on a person's behavior. In general, the more obtrusive the observation and measurement method, the greater the likelihood of reactivity. Maximum obtrusiveness exists when the person observing and recording the target behavior is the subject of the behavior change program, and reactivity is very likely.

Although reactivity caused by a researcher's measurement system represents uncontrolled variability in a study and must be minimized as much as possible, the reactive effects of self-monitoring are welcome from a clinical perspective. Not only does self-monitoring often change behavior, but also the change is typically in the educationally or therapeutically desired direction.

Behavior analysts have taught adults to use self-monitoring to decrease smoking (Lipinski, Black, Nelson, & Ciminero, 1975; McFall, 1977), increase physical activity (Kurti & Dallery, 2013) and calorie expenditure (Donaldson & Normand, 2009), and stop biting their nails (Maletzky, 1974). Students with and without disabilities have used self-monitoring to be on task more often in the classroom (Legge, DeBar, & Alber-Morgan, 2010; Wills & Mason, 2014), decrease disruptive behaviors (Kamps, Conklin, & Wills, 2015; Martella, Leonard, Marchand-Martella, & Agran, 1993), improve reading comprehension (Crabtree, Alber-Morgan, & Konrad, 2010), increase performance in a variety of academic subject areas (Holifield, Goodman, Hazelkorn, & Heflin, 2010; Wolfe, Heron, & Goddard, 2000), and complete homework assignments (Falkenberg & Barbetta, 2013). Classroom teachers have used self-monitoring to increase their use of specific praise statements during classroom instruction (Hager, 2012; Simonsen, MacSuga, Fallon, & Sugai, 2013) and the fidelity with which they conduct instructional procedures (Belfiore, Fritts, & Herman, 2008; Pinkelman & Horner 2016; Plavnick, Ferreri, & Maupin, 2010).

In one of the first published accounts of self-monitoring by children, Broden, Hall, and Mitts (1971) analyzed the effects of self-recording on the behavior of two eighth-grade students. Liza was earning a D– in history and exhibited poor study behavior during the lecture format class. Using 10-sec momentary time sampling for 30 minutes each school day, an observer seated in the back of the classroom (Liza was not told she was being observed) produced a 7-day baseline showing that Liza exhibited study behaviors (e.g., faced the teacher, took notes when appropriate) an average of 30% of the observation intervals, despite two conferences with the school counselor in which she promised to "really try." Prior to the eighth session,

the counselor gave Liza a piece of paper with three rows of 10 squares and directed her to record her study behavior "when she thought of it" during her history class sessions. Some aspects of study behavior were discussed at this time, including a definition of what constituted studying.

> Liza was instructed to take the slip to class each day and to record a "+" in the square if she was studying or had been doing so for the last few minutes, and a "−" if she was not studying at the time she thought to record. Sometime before the end of the school day she was to turn it in to the counselor. (p. 193)

Figure 29.3 shows the results of Liza's self-monitoring. Her level of study behavior increased to 78% (as measured by the independent observer) and stayed at approximately that level during Self-Recording 1, quickly decreased to baseline levels when self-recording was terminated during Baseline 2, and averaged 80% during Self-Recording 2. During Self-Recording Plus Praise, Liza's teacher attended to her whenever he could during history class and praised her for study behavior whenever possible. Liza's level of study behavior during this condition increased to 88%.

The bottom graph in Figure 29.3 shows the number of times per session the observer recorded teacher attention toward Liza. That teacher attention did not correlate in any apparent way with changes in Liza's study behavior during the first four phases of the experiment suggests that teacher attention—which often exerts a powerful influence on student behavior—was not a confounding variable and that the improvements in Liza's study behavior most likely can be attributed to the self-recording procedure. However, the effects of self-monitoring may have been confounded by the fact that Liza turned her self-recording slips in to the counselor before the end of each school day, and at weekly student–counselor conferences she received praise from the counselor for recording slips with a high percentage of plus marks.

In the second experiment reported by Broden and colleagues (1971), self-monitoring was used by Stu, an eighth-grade student who talked out in class "continually." An observer recorded Stu's talk-outs during both parts of a math class that met before and after lunch. Self-recording was begun first during the before-lunch portion of the math class. The teacher handed Stu a slip of paper on which was marked a 2-inch by 5-inch rectangular box and the instruction, "Put a mark every time you talk out" (p. 196). Stu was told to use the recording slip and turn it in after lunch. At the top of the recording slip was a place for the student's name and the date. No other instructions were given to Stu, nor were any consequences or other contingencies

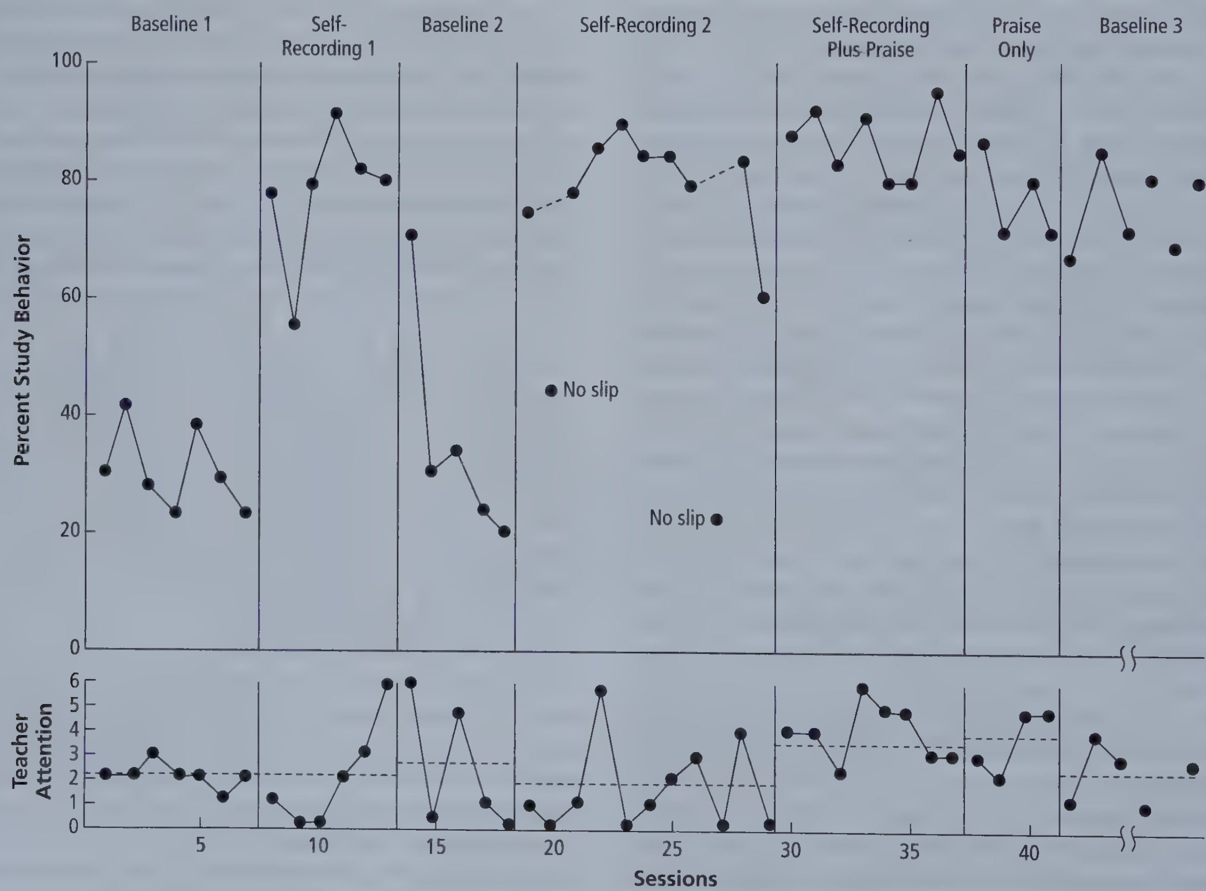

Figure 29.3 Percentage of observed intervals in which an eighth-grade girl paid attention in class.

Republished with permission of Society for the Experimental Analysis of Behavior, Inc., from The Effect of Self-Recording on the Classroom Behavior of Two Eighth-Grade Students, M. Broden, R. V. Hall, and B. Mitts, 1971, *Journal of Applied Behavior Analysis*, *4*, p. 194. Permission conveyed through Copyright Clearance Center, Inc.

applied to his behavior. Self-recording was later implemented during the second half of the math class. During the pre-lunch portion of the math class, Stu's baseline rate of 1.1 talk-outs per minute was followed by a rate of 0.3 talk-outs per minute when he self-recorded. After lunch Stu talked out at an average rate of 1.6 times per minute before self-recording and 0.5 times per minute during self-recording.

The combination reversal and multiple baseline design showed a clear functional relation between the self-monitoring procedure and Stu's reduced talk-outs. During the final phase of the experiment, however, Stu talked out at rates equal to initial baseline levels, even though self-recording was in effect. Broden and colleagues (1971) suggested that the lack of effect produced by self-recording during the final phase may have resulted from the fact that "no contingencies were ever applied to differential rates of talking out and the slips thus lost their effectiveness" (p. 198). It is also possible that the initial decreases in talk-outs attributed to self-recording were confounded by Stu's expectations of some form of teacher reinforcement.

As can be seen from these two experiments, it is extremely difficult to isolate self-monitoring as a straightforward, "clean" procedure; self-monitoring almost always entails other contingencies. Nevertheless, the various and combined procedures that constitute self-monitoring are effective in changing behavior.

Self-Evaluation

Self-monitoring is often combined with goal setting and self-evaluation. A person using **self-evaluation** (also called *self-assessment*) compares her performance with a predetermined goal or standard. Self-evaluation can be aided by self-graphing self-collected data (Kasper-Ferguson & Moxley, 2002; Stolz, Itoi, Konrad, & Alber-Morgan, 2008). For example, Grossi and Heward (1998) taught four restaurant trainees with developmental disabilities to select productivity goals, self-monitor their work, and self-evaluate their performance against a competitive productivity standard (i.e., the typical rate at which nondisabled restaurant employees perform the task in competitive settings). Job tasks in this study included scrubbing pots and pans, loading a dishwasher, busing and setting tables, and mopping and sweeping floors.

Self-evaluation training with each trainee took approximately 35 minutes across three sessions and consisted of five parts: (1) rationale for working faster (e.g., finding and keeping a job in a competitive setting), (2) goal setting (trainee was shown a simple line graph of his baseline performance compared to the competitive standard and prompted to set a productivity goal), (3) use of timer or stopwatch, (4) self-monitoring and how to chart self-recorded data on a graph that showed the competitive standard with a shaded area, and (5) self-evaluation (comparing his own work against the competitive standard and making self-evaluative statements, e.g., "I'm not in the shaded area. I need to work faster." or "Good, I'm in the area."). When a trainee met his goal for 3 consecutive days, a new goal was selected. At that time, all four trainees had selected goals within the competitive range.

The work productivity of all four trainees increased as a function of the self-evaluation intervention. Figure 29.4 shows the results for one of the participants, Chad, a 20-year-old man with mild cognitive disabilities, cerebral palsy, and a seizure disorder. For the 3 months prior to the study, Chad had been training at two work tasks at the dishwashing job station: scrubbing cooking pots and pans and racking dishes (a six-step behavior chain for loading an empty dishwasher rack with dirty dishes). Throughout the study, pot scrubbing was measured during 10-min observation sessions both before and after the daily lunch operation. Racking dishes was measured using a stopwatch to time to the nearest second how long a trainee took to load a rack of dishes; 4 to 8 racks per session were timed during the busiest hour of the lunch shift. After each observation session during baseline, Chad received feedback on the accuracy and quality of his work. No feedback was given during baseline on the productivity of his performance.

During baseline, Chad scrubbed an average of 4.5 pots and pans every 10 minutes, and none of his 15 baseline trials was within the competitive range of 10 to 15 pots. Chad's pot scrubbing rate increased to a mean of 11.7 pots during self-evaluation, with 76% of 89 self-evaluation trials at or above the competitive range. During baseline, it took Chad a mean of 3 minutes 2 seconds to load one rack of dishes, and 19% of his 97 baseline trials were within the competitive range of 1 to 2 minutes. During self-evaluation, Chad's time to load one rack improved to a mean of 1 minute 55 seconds, and 70% of the 114 self-evaluation trials were within the competitive range. At the end of the study, three of the four trainees stated that they liked to time and record their work performance. Although one trainee stated it was "too stressful" to time and record his work, he said that self-monitoring helped him show other people that he could do the work.

Participants who have self-evaluated their behavior as captured on video have improved their posture while sitting at computer work stations (Sigurdsson & Austin, 2008) and their performance of complex yoga postures (Downs, Miltenberger, Biedronski, & Witherspoon, 2015).

Self-Monitoring with Reinforcement

Self-monitoring is often part of an intervention package that includes feedback and reinforcement for meeting either self- or teacher-selected goals (e.g., Bulla & Frieder, 2017; Christian & Poling, 1997; Olympia et al., 1994). The reinforcer may be self-administered or teacher delivered. For example, Koegel, Koegel, Hurley, and Frea (1992) taught four children with autism between the ages of 6 and 11 to obtain their own reinforcers after they had self-recorded a criterion number of appropriate responses to questions from others (e.g., "Who drove you to school today?").

Teacher-delivered reinforcement was a component of a self-monitoring intervention used by Martella and colleagues (1993) to help Brad, a 12-year-old student with mild intellectual disabilities, reduce the number of negative statements he made during classroom activities (e.g., "I hate this #*%@! calculator," "Math is crappy"). Brad self-recorded negative statements during two class periods, charted the number on a graph, and then compared his count with the count obtained by a student teacher. If Brad's self-recorded data agreed with the teacher at

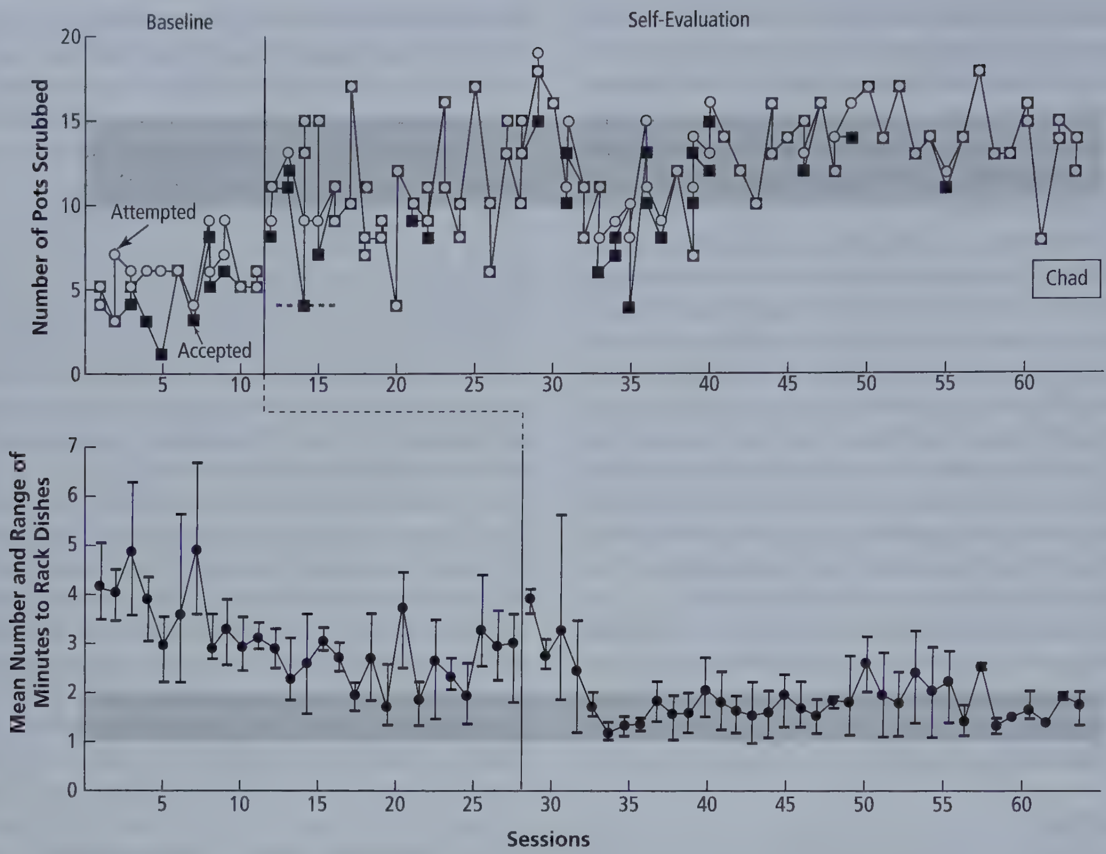

Figure 29.4 Number of pots scrubbed in 10 minutes and the mean and range of minutes to load a rack of dishes in the dishwasher during baseline and self-evaluation conditions. Shaded bands represent the competitive performance range of restaurant workers without disabilities. The dashed horizontal line represents Chad's self-selected goal; no dashed line means that Chad's goal was within the competitive range. Vertical lines through data points on the bottom graph show the range of Chad's performance across 4 to 8 trials.

a level of 80% or higher, he received his choice from a menu of "small" reinforcers (items costing 25 cents or less). If Brad's self-recorded data agreed with the teacher's data and were at or below a gradually declining criterion level for four consecutive sessions, he was allowed to choose a "large" (more than 25 cents) reinforcer (see Figure 30.16).

Why Does Self-Monitoring Work?

The behavioral mechanisms that account for the effectiveness of self-monitoring are not fully understood. Some behavior theorists suggest that self-monitoring is effective in changing behavior because it evokes self-evaluative statements that serve either to reinforce desired behaviors or to punish undesired behaviors. Cautela (1971) hypothesized that a child who records on a chart that he has completed his chores may emit covert verbal responses (e.g., "I am a good boy") that serve to reinforce chore completion. Malott (1981) suggested that self-monitoring improves performance because of what he called *guilt control.* Self-monitoring less-than-desirable behavior produces covert guilt statements that can be avoided by improving one's performance. That is, the target behavior is strengthened through negative reinforcement by escape and avoidance of the guilty feelings that occur when one's behavior is "bad."

Descriptions of the self-monitoring techniques used by two famous authors apparently agreed with Malott's guilt control hypothesis. Novelist Anthony Trollope, writing in his 1883 autobiography, stated:

> When I have commenced a new book, I have always prepared a diary, divided into weeks, and carried on for the period which I have allowed myself for the completion of the work. In this I have entered, day by day, the number of pages I have written, so that if at any time I have slipped into idleness for a day or two, the record of that idleness has been there staring me in the face, and demanding of me increased labour, so that the deficiency might be supplied. . . . I have allotted myself so many pages a week. The average number has been about 40. It has been placed as low as 20, and has risen to 112. And as a page is an ambiguous term, my page has been made to contain 250 words; and as words, if not watched, will have a tendency to straggle, I have had every word counted as I went. . . . There has ever been the record before me, and a week passed with an

insufficient number of pages has been a blister to my eye and a month so disgraced would have been a sorrow to my heart. (from Wallace, 1977, p. 518)

Guilt control also helped to motivate the legendary Ernest Hemingway. Novelist Irving Wallace (1977) reported the following extract from an article by George Plimpton about the self-monitoring technique used by Hemingway.

> He keeps track of his daily progress—"so as not to kid myself"—on a large chart made out of the side of a cardboard packing case and set up against the wall under the nose of a mounted gazelle head. The numbers on the chart showing the daily output of words differ from 450, 575, 462, 1250, back to 512, the higher figures on days Hemingway put in extra work so he won't feel guilty spending the following day fishing on the Gulf Stream. (p. 518)

Exactly which principles of behavior are operating when self-monitoring changes the target behavior is not known because much of the self-monitoring procedure consists of private, covert behaviors. In addition to the problem of access to these private events, self-monitoring is usually confounded by other variables. Self-monitoring is often part of a self-management package in which contingencies of reinforcement, punishment, or both, are included, either explicitly (e.g., "If I run 10 miles this week, I can go to the movies.") or implicitly (e.g., "I've got to show my record of calories consumed to my wife."). Regardless of the principles of behavior involved, however, self-monitoring is often an effective procedure for changing one's behavior.

Self-Monitoring Guidelines and Procedures

Practitioners should consider the following suggestions when implementing self-monitoring with their clients.

Provide Materials That Make Self-Monitoring Easy

If self-monitoring is difficult, cumbersome, or time-consuming, at best it will be ineffective and disliked by the participant, and at worst it may have negative effects on the target behavior. Provide participants with materials and devices that make self-monitoring as simple and efficient as possible. All of the low-tech devices and procedures for measuring behavior described in Chapter 4 (e.g., paper and pencil, wrist counters, hand-tally counters, timers, stopwatches) can be used for self-monitoring. For example, a teacher wanting to praise students at least 10 times during a class period could put 10 pennies in her pocket prior to the start of class. Each time she praises a student's behavior, she moves one coin to another pocket.

Recording forms for most self-monitoring situations should be very simple. Self-recording forms consisting of little more than a series of boxes or squares are often effective (e.g., Broden et al., 1971). At various intervals, the participant might write a plus or minus, circle yes or no, or mark an X on a smiling face or sad face, in a kind of momentary time sampling procedure; or he could record a count of the number of responses made during a just-completed interval.

Recording forms can be created for self-monitoring specialized tasks or a chain of behaviors. Dunlap and Dunlap (1989) taught students with learning disabilities to self-monitor the steps they used to solve subtraction problems with regrouping. Each student self-monitored his work by recording a plus or a minus next to each step on an individualized checklist of steps (e.g., "I underlined all the top numbers that were smaller than the bottom."; "I crossed out only the number next to the underlined number and made it one less." [p. 311]) designed to prompt the student from committing specific types of errors.

Lo (2003) taught elementary students who were at risk for behavioral disorders to use the form shown in Figure 29.5 to self-monitor whether they worked quietly, evaluated their work, and followed a prescribed sequence for obtaining teacher

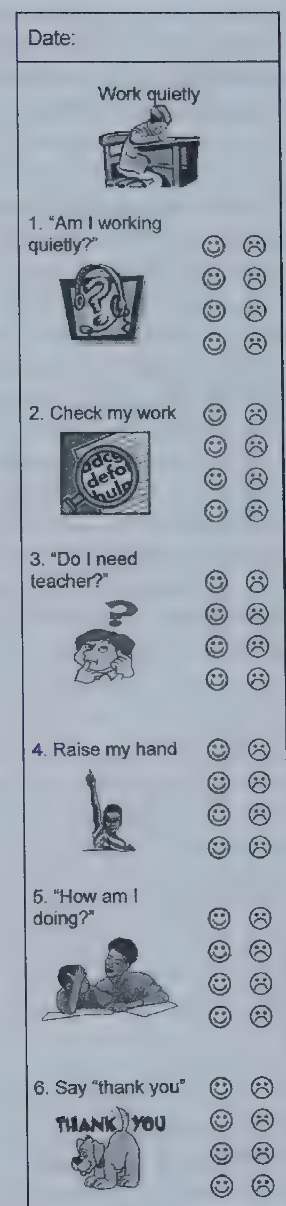

Figure 29.5 Form used by elementary school students to self-monitor whether they worked quietly and followed a prescribed sequence for recruiting teacher assistance.

assistance during independent seatwork activities. The form, which was taped to each student's desk, functioned as a reminder to students of the expected behaviors and as a device on which they self-recorded those behaviors.

"Countoons" are self-monitoring forms that illustrate the contingency with a series of cartoon-like frames. A countoon reminds young children of not only what behavior to record but also what consequences will follow if they meet specified performance criteria. Daly and Ranalli (2003) created six-frame countoons that enable students to self-record an inappropriate behavior and an incompatible appropriate behavior. In the countoon shown in Figure 29.6, Frames F1 and F4 show the student doing her math work, appropriate behavior that is counted in Frame F5. The criterion number of math problems to meet the contingency—in this case, 10—is also indicated in Frame F5. Frame F2 shows the student talking with a friend, the inappropriate behavior to be counted in F3. The student must not chat more than 6 times to meet the contingency. The "What Happens" frame (F6) depicts the reward the student will earn by meeting both parts of the contingency. Daly and Ranalli have provided detailed steps for creating countoons and using them to teach self-management skills to children.

Self-monitoring forms can also be designed to enable self-recording of multiple tasks across days. For example, teachers working with secondary students might find the Classroom Performance Record (CPR) developed by Young and colleagues (1991) an effective way to assist students with monitoring their assignments, completion of homework, points earned, and citizenship scores. The form also provides students with information about their current status in the class, their likely semester grade, and tips for improving their performance.

Self-monitoring interventions to improve fitness can be aided by smartwatches and other digital devices that automatically count steps, measure heart rate, and record variables such as time and distance (e.g., Hayes & Van Camp, 2015; Valbuena, Miltenberger, & Solley, 2015). In one study, college student athletes self-monitored their class attendance and arrival time by text messaging their academic counselors (Bicard, Lott, Mills, Bicard, & Baylot-Casey, 2012).

Provide Supplementary Cues or Prompts

Although some self-recording devices—a recording form taped to a student's desk, a notepad for counting calories carried in a dieter's shirt pocket, a golf counter on a teacher's wrist—serve as continual reminders to self-monitor, additional prompts or cues to self-monitor are often helpful. Researchers and practitioners have used a variety of auditory, visual, and tactile stimuli as cues and prompts for self-monitoring.

Auditory prompts in the form of prerecorded signals or tones have been widely used to cue self-monitoring in classrooms (e.g., Todd, Horner, & Sugai, 1999). For example, in a study by Glynn, Thomas, and Shee (1973), second-graders placed a checkmark in a series of squares if they thought they were on task at the moment they heard a tape-recorded beep. A total of 10 beeps occurred at random intervals during a 30-min class period. Using a similar procedure with a digital device, Gulchak (2008) taught an 8-year-old boy diagnosed with emotional and behavior disorders to use a stylus to check *Yes* or *No* under the heading "Are You On-Task?" on a handheld computer when the computer's alarm chimed at 10-min intervals.

Ludwig (2004) used visual cues on the classroom board to prompt kindergarten children to self-record their productivity during a morning seatwork activity in which they wrote answers on individual worksheets to items, problems, or questions that the teacher had printed on a large whiteboard on the classroom wall. The work was divided into 14 sections by topic and covered a variety of curriculum areas (e.g., spelling, reading comprehension, addition and subtraction problems, telling time, money).

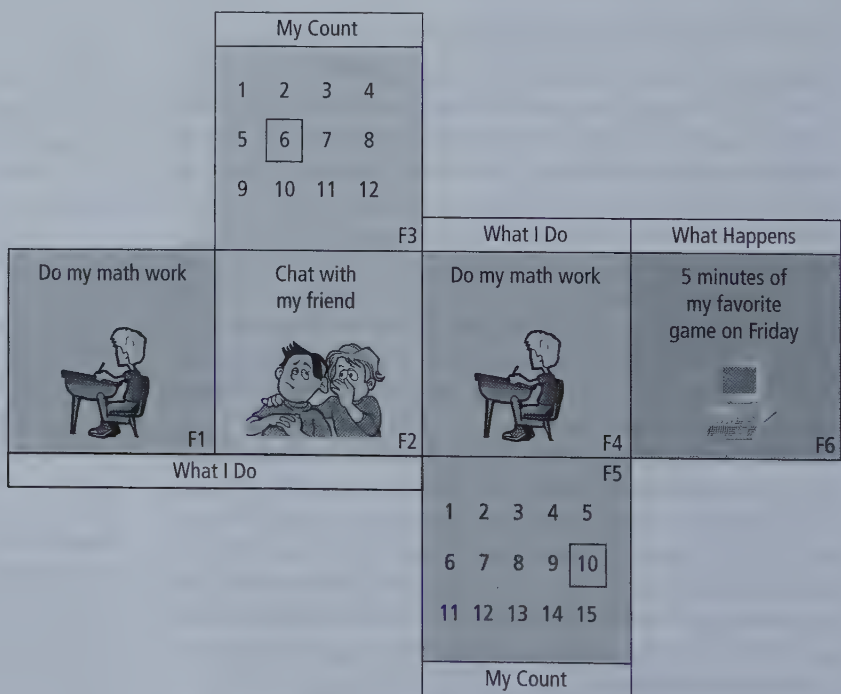

Figure 29.6 Example of a countoon that can be taped to a student's desk as a reminder of target behaviors, the need to self-record, and the consequence for meeting the contingency.

Republished with permission of Council for Exceptional Children, from Using Countoons to Teach Self-Monitoring Skills, P. M. Daly and P. Ranalli, 2003, *Teaching Exceptional Children*, *35*(5), p. 32. Permission conveyed through Copyright Clearance Center, Inc.

At the end of each section, the experimenter drew a smiley face with a number from 1 to 14. The numbered smiley faces drawn on the board corresponded to 14 numbered smiley faces on each student's self-monitoring card.

Digital devices can provide unobtrusive visual prompts to self-monitor. Clemons and colleagues (2016) programmed a handheld tablet's touchscreen to flash "Am I on-task?" followed by the choices "yes" and "no" at 30-sec or 1-min intervals. Three high school students with varying disabilities exhibited improved levels of on-task behavior when using the system in general and self-contained special education classrooms.

Tactile prompts can also be used to signal self-recording opportunities. For example, the *MotivAider(R)* (www.habitchange.com) is a small electronic device that vibrates at fixed or variable time intervals programmed by the user. This device is excellent for signaling people to self-monitor or perform other self-management tasks (e.g., Legge et al., 2010) or to prompt practitioners to attend to the behavior of students or clients (Flaute, Peterson, Van Norman, Riffle, & Eakins, 2005).

Prompts to self-monitor, whatever their form, should be as unobtrusive as possible so they do not disrupt the participant or others. As a general rule, practitioners should provide frequent prompts to self-monitor at the beginning of a self-management intervention and gradually reduce their number as the participant becomes more proficient and skilled with self-monitoring.

Self-Monitor the Most Important Dimension of the Target Behavior

Self-monitoring is measurement. As we saw in Chapter 4, there are various dimensions by which a given behavior can be measured. What dimension of the target behavior should be self-monitored? A person should self-monitor the dimension that, should desired changes in its value occur, would yield the most direct and significant progress toward his self-management goal. For example, a man wanting to lose weight by eating less food could measure the number of bites he takes throughout the day (count), the number of bites per minute at each meal (rate), how much time elapses from the time he sits down at the table to when he takes the first bite (latency), how long he pauses between bites (interresponse time), and/or how long his meals last (duration). Although daily measures of each of these dimensions would provide some quantitative information about the man's eating, none of the dimensions would be as directly related to his goal as would the total number of calories he consumes each day.

Numerous studies have examined the question of whether students should self-monitor their on-task behavior or their academic performance or productivity. Some researchers have found self-monitoring of attention more effective (Harris, Friedlander, Saddler, Frizzelle, & Graham, 2005; Kneedler & Hallahan, 1981), others have reported advantages for self-monitoring performance (Lam, Cole, Shapiro, & Bambara, 1994; Maag, Reid, & DiGangi, 1993; Reid, 1996), and some have found the two procedures equally effective (Carr & Punzo, 1993; Shimabukuro, Pratter, Jenkins, & Edelen-Smith, 2000). Although self-monitoring either attention or performance results in increased on-task behavior, students tend to complete more academic responses when self-monitoring productivity than when self-recording on-task behavior (e.g., Maag et al., 1993; Lam et al., 1994; Reid & Harris, 1993). Additionally, most students prefer self-monitoring academic performance to self-recording on-task behavior (e.g., "You could say the words while you counted them." [Harris et al., 2005, p. 151]).

In general, we recommend teaching students to self-monitor a measure of academic productivity (e.g., number of problems or items attempted, number correct) rather than whether they are on task. This is because increasing on-task behavior, whether by self-monitoring or by contingent reinforcement, does not necessarily result in a collateral increase in productivity (e.g., Marholin & Steinman, 1977; McLaughlin & Malaby, 1972; Wolfe et al., 2000). By contrast, when productivity is increased, improvements in on-task behavior almost always occur. However, a student whose persistent off-task and disruptive behaviors create problems for him or others in the classroom may benefit more from self-monitoring on-task behavior, at least initially.

Self-Monitor Early and Often

In general, each occurrence of the target behavior should be self-recorded as soon as possible. However, the act of self-monitoring a behavior the person wants to increase should not disrupt "the flow of the behavior" (Critchfield, 1999). Self-monitoring behaviors that produce natural or contrived response products (e.g., answers on academic worksheets, words written) can be conducted after the session by permanent product measurement (see Chapter 4).

Relevant aspects of some target behaviors can be self-monitored even before the behavior has occurred. Self-recording a response early in a behavior chain that leads to an undesired behavior the person wants to decrease may be more effective in changing the target behavior in the desired direction than recording on the terminal behavior in the chain. For example, Rozensky (1974) reported that when a woman who had been a heavy smoker for 25 years recorded the time and place she smoked each cigarette, there was little change in her rate of smoking. She then began recording the same information each time she noticed herself beginning the chain of responses that led to smoking: reaching for her cigarettes, removing a cigarette from the pack, and so on. She stopped smoking within a few weeks of self-monitoring in this fashion.

Generally, a person should self-monitor more often at the beginning of a behavior change program. If and as performance improves, self-monitoring can occur less often. For example, Rhode, Morgan, and Young (1983) had students with behavioral disorders begin self-evaluating (on a 0- to 5-point scale) the extent to which they followed classroom rules and completed academic work at 15-min intervals throughout the school day. Over the course of the study, the self-evaluation intervals were increased gradually, first to every 20 minutes, then every 30 minutes, then once per hour. Eventually, the self-evaluation cards were withdrawn and students orally reported their self-evaluations. In the final self-evaluation condition, the students verbally self-evaluated their compliance with classroom rules and academic work on an average of every 2 days (i.e., a variable ratio [VR] 2-day schedule).

Reinforce Accurate Self-Monitoring

Some researchers have reported little correlation between the accuracy of self-monitoring and its effectiveness in changing the behavior being recorded (e.g., Kneedler & Hallahan, 1981; Marshall, Lloyd, & Hallahan, 1993). It appears that accurate self-monitoring is neither a sufficient nor a necessary condition for behavior change. For example, Hundert and Bucher (1978) found that, even though students became highly accurate in self-scoring their arithmetic, their performance on the arithmetic itself did not improve. In contrast, in the Broden and colleagues (1971) study, both Liza and Stu's behavior improved even though their self-recorded data seldom matched the data from independent observers. Nevertheless, accurate self-monitoring is desirable, especially when participants are using their self-recorded data as the basis for self-evaluation or self-administered consequences.

Although some studies have shown that young children can accurately self-record their behavior in the absence of external contingencies for accuracy (e.g., Ballard & Glynn, 1975; Glynn et al., 1973), other researchers have reported low agreement between the self-reported data and the data collected by independent observers (Kaufman & O'Leary, 1972; Turkewitz, O'Leary & Ironsmith, 1975). One factor that seems to affect the accuracy of self-scoring is the use of self-reported scores as a basis for reinforcement. Santogrossi, O'Leary, Romanczyk, and Kaufman (1973) found that, when children self-evaluated their own work and those self-produced evaluations determined levels of token reinforcement, their self-monitoring accuracy deteriorated over time. Similarly, Hundert and Bucher (1978) found that students who previously had accurately self-scored their arithmetic assignments greatly exaggerated their scores when higher scores resulted in points that could be exchanged for prizes.

Rewarding children for producing self-recorded data that match the data of an independent observer and spot-checking students' self-scoring reports can increase the accuracy of self-monitoring by young children. Drabman, Spitalnik, and O'Leary (1973) used these procedures in teaching children with behavior disorders to self-evaluate their own classroom behavior.

> Now something different is going to happen. If you get a rating within plus or minus one point of my rating, you can keep all your points. You lose all your points if you are off my rating by more than plus or minus one point. In addition, if you match my rating exactly you get a bonus point. (O'Leary, 1977, p. 204)

After the children demonstrated that they could evaluate their own behavior reliably, the teacher began checking only 50% of the children's self-ratings by pulling names from a hat at the end of the period, then 33% of the children, then 25%, then 12%. During the last 12 days of the study, she did not check any child's self-rating. Throughout this period of reduced checks and finally no checks at all, the children continued to self-evaluate accurately. Rhode and colleagues (1983) used a similar faded matching technique.

Additional examples and techniques for teaching self-monitoring to children can be found in Joseph and Konrad (2009); McCollow, Curiel, Davis, and Sainato (2016); and Rafferty (2010).

SELF-ADMINISTERED CONSEQUENCES

Arranging for specific consequences to follow occurrences (or nonoccurrences) of one's behavior is a fundamental strategy of self-management. In this section, we review a variety of tactics people have used to self-reinforce and self-punish. First, we briefly examine some of the conceptual issues raised by the concept of "self-reinforcement."

Is Self-Reinforcement Possible?

Skinner (1953) pointed out that *self-reinforcement* should not be considered synonymous with the principle of operant reinforcement.

> The place of operant reinforcement in self-control is not clear. In one sense, all reinforcements are self-administered since a response may be regarded as "producing" its reinforcement, but "reinforcing one's own behavior" is more than this. . . . Self-reinforcement of operant behavior presupposes that the individual has it in his power to obtain reinforcement but does not do so until a particular response has been emitted. This might be the case if a man denied himself all social contacts until he had finished a particular job. Something of this sort unquestionably happens, but is it operant reinforcement? It is roughly parallel to the procedure in conditioning the behavior of another person. But it must be remembered that the individual may at any moment drop the work in hand and obtain the reinforcement. We have to account for his not doing so. It may be that such indulgent behavior has been punished—say, with disapproval—except when a piece of work has just been completed. (pp. 237–238)

In his discussion of self-reinforcement, Goldiamond (1976a) continued with Skinner's example and stated that the fact that a person "does not cheat, but engages in the task, cannot be explained simply by resort to *his* self-reinforcement by social contact, which he makes available contingent on his finishing the job" (p. 510). In other words, the variables influencing the controlling response—in this case abstaining from social contact until the job is complete—must still be accounted for; simply citing self-reinforcement as the cause is an explanatory fiction.

The issue is not whether procedures labeled as "self-reinforcement" often work to change behavior in ways that resemble the defining effect of reinforcement; they do. However, a careful examination of instances of self-reinforcement reveals that something more than, or different from, a straightforward application of positive reinforcement is involved (e.g., Brigham, 1980; Catania, 2013; Goldiamond, 1976a, 1976b). As a technical term, *self-reinforcement* (as also, *self-punishment*) is a misnomer, and the issue is not merely a semantic one, as some writers have suggested (e.g., Mahoney, 1976). Assigning the effectiveness of a behavior change tactic to a well-understood principle of behavior when something other than, or in addition to, that principle is operating overlooks relevant variables that may hold the key to a fuller understanding of the tactic. Considering the analysis of a behavioral episode complete once it has been identified as a case of self-reinforcement precludes further search for other relevant variables.

We agree with Malott (2005a, 2012; Malott & Shane, 2014), who argued that performance-management contingencies, whether designed and implemented by oneself or by others, are best viewed as rule-governed analogs of reinforcement and punishment contingencies because the response-to-consequence delay is too great.[7] Malott (2005a) provided the following examples of self-management contingencies as analogs to negative reinforcement and punishment contingencies:

> [Consider the] contingency, *Every day I eat more than 1,250 calories, I will give someone else $5 to spend frivolously*, like a despised roommate or despised charity, though for many of us, the loss of $5 to a beloved charity is sufficiently aversive that the thought of it will punish overeating. [This] contingency is an analog to a penalty [punishment] contingency, an analog because the actual loss of the $5 will normally occur more than 1 minute after exceeding the 1,250 calorie limit. Such analog penalty contingencies are effective in decreasing undesirable behavior. And to increase desirable behavior, an analog to an avoidance [negative reinforcement] contingency works well: *Every day I exercise for one hour, I avoid paying a $5 fine*. But, if you have not finished your hour by midnight, you must pay the $5. (p. 519, emphasis in original, words in brackets added)

Self-Administered Consequences to Increase Behavior

A person can increase the target behavior in a self-management program by applying contingencies that are analogs to positive and negative reinforcement. Self-selected consequences can be delivered directly (the self-manager accesses the consequence herself) or indirectly (another person provides the consequence).

Self-Management Analogs of Positive Reinforcement

A variety of target behaviors have improved when students determined the number of tokens, points, or minutes of free time earned based on self-assessment of their performance (Glynn, 1970; Koegel et al., 1992; Olympia et al., 1994). In a self-experiment, Craig (2010) decreased the number of times he bit his fingernails by awarding himself points using a token-based differential reinforcement of other behavior (DRO) procedure. A wristwatch with a countdown timer signaled 1-hr DRO intervals. The effects of interventions featuring self-administered rewards are difficult to evaluate because they are typically confounded by other variables. In a review of self-reinforcement research, Jones, Nelson, and Kazdin (1977) identified participants' previous history, criterion setting, self-monitoring, self-evaluation, external contingencies on the self-reinforcing response, external contingencies on the target behavior, and actual or suspected surveillance as likely confounding variables.

A study by Ballard and Glynn (1975) controlled for self-monitoring as a contributor to the effects of self-reinforcement. Third-graders were taught after a baseline condition to self-score and self-record several aspects of their writing—number of sentences, number of describing words, and number of action words. Self-monitoring had no effect on any of the variables measured, even though the students handed in their counting sheets with their writing each day. The children were then given a notebook in which to record their points, which could be exchanged at the rate of one point per minute for each student's choice of activities during an earned-time period each day. The self-reinforcement procedure resulted in large increases in each of the three dependent variables.

In studies on self-recruited reinforcement, students are taught to periodically self-evaluate their work and then show it to their teacher and request feedback or assistance (Alber, Heward, & Hippler, 1999; Craft, Alber, & Heward, 1998; Rouse et al., 2014). In a sense, students administer their own reinforcer by recruiting the teacher's attention, which often results in praise and other forms of reinforcement (see Alber & Heward, 2000 for a review).

Todd and colleagues (1999) taught an elementary student to use a self-management system that included self-monitoring, self-evaluation, and self-recruited reinforcement. Kyle was a 9-year-old boy diagnosed with a learning disability and receiving special education services in reading, math, and language arts. Kyle's individualized education program (IEP) also included several objectives for problem behavior (e.g., disrupting independent and group activities, teasing and taunting classmates, and saying sexually inappropriate comments). The classroom teacher's goal setting and daily evaluation had proven ineffective. An "action team" conducted a functional assessment (see Chapter 27) and designed a support plan that included the self-management system.

Kyle was taught how to use the self-management system during two 15-min one-on-one training sessions in which he practiced self-recording numerous role-played examples and nonexamples of on-task and off-task behavior and learned appropriate ways to recruit teacher attention and praise. For self-monitoring, Kyle listened with a single earplug to a 50-min cassette tape on which 13 checkpoints (e.g., "check one," "check two") had been prerecorded on a variable interval (VI) 4-min schedule (ranging from 3- to 5-min intervals between checkpoints). Each time Kyle heard a checkpoint, he marked a plus (if he had been working quietly and keeping his hands, feet, and objects to himself) or a zero (if he had been teasing peers and/or not working quietly) on a self-recording card.

Todd and colleagues (1999) described the recruitment of teacher praise and how Kyle's special program was integrated into the reinforcement system for the entire class:

> Each time Kyle marked three pluses on his card he raised his hand (during instruction) or walked up to the teacher (during group project time) and requested feedback on his performance. The teacher acknowledged Kyle's good work and placed a mark on his self-monitoring card to show where he should begin a new count of three pluses. In addition to these within-session contingencies, Kyle could earn a self-manager sticker at the end of each class period if he had no more than two zeroes for the period. Stickers were earned by all students in the class for appropriate behavior and were pooled weekly for class rewards. Because these stickers were combined, Kyle's stickers were valued by all the students and provided opportunities for positive peer attention. (p. 70)

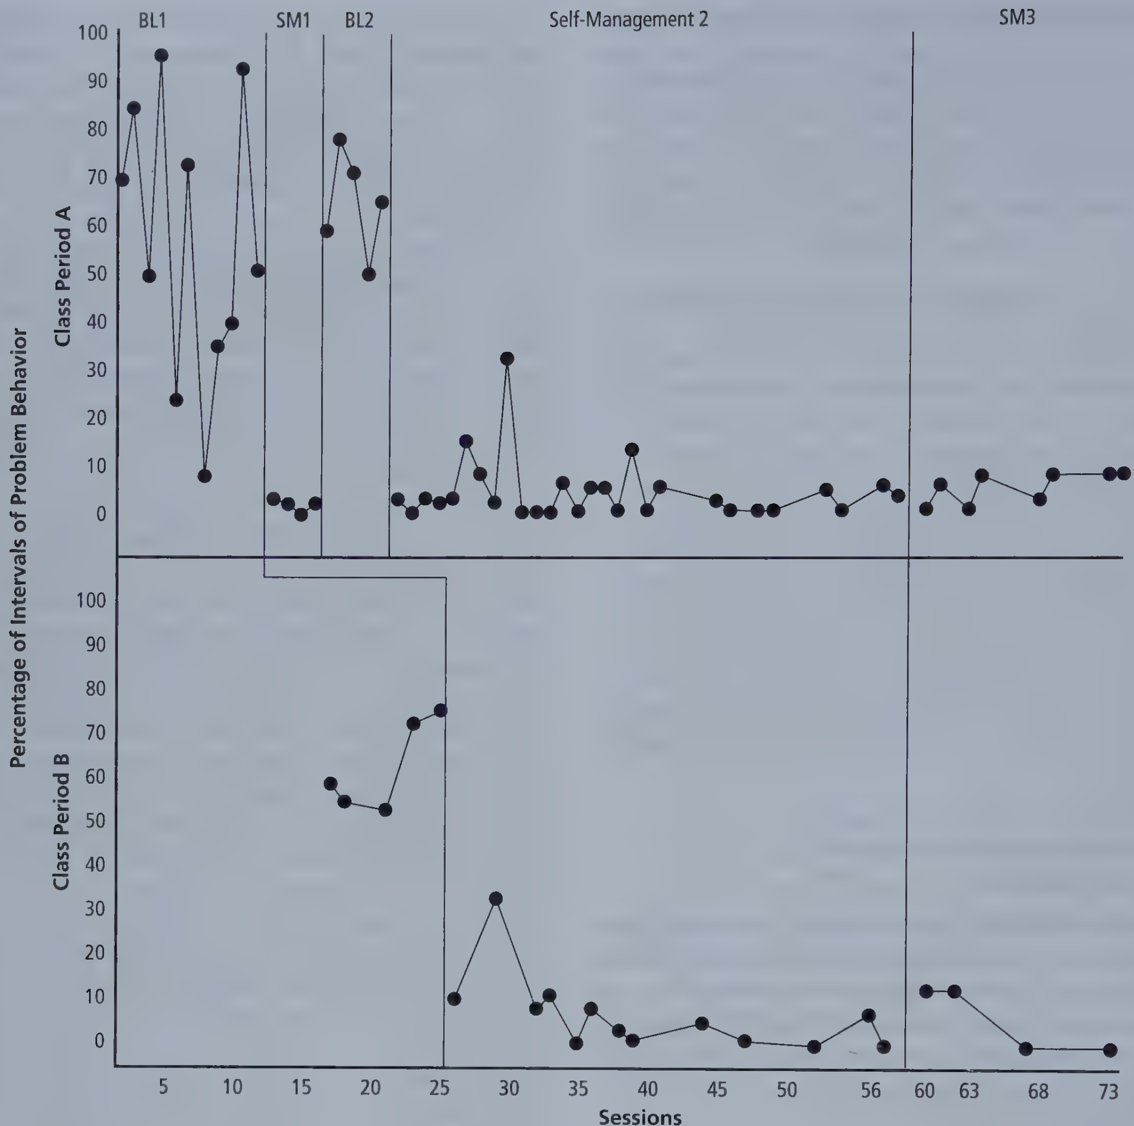

Figure 29.7 Problem behaviors by a 9-year-old boy during 10-min probes across two class periods during baseline (BL) and self-management (SM) conditions.

Republished with permission of Pro-Ed, Inc., from Self-Monitoring and Self-Recruited Praise: Effects on Problem Behavior, Academic Engagement, and Work Completion in a Typical Classroom, A. W. Todd, R. H. Horner, and G. Sugai, 1999, *Journal of Positive Behavior Interventions*, *1*, p. 71. Permission conveyed through Copyright Clearance Center, Inc.

Procedures for the second self-management phase (SM2) were the same as for the first phase; during the third phase (SM3), Kyle used a 95-min tape on which 16 checkpoints were prerecorded on a VI 5-min schedule (ranging from 4 to 6 minutes). When Kyle used the self-management system, the percentage of intervals in which he engaged in problem behavior was much lower than baseline (BL) levels (see Figure 29.7). Large increases in on-task behavior and completion of academic work were also noted. An important outcome of this study was that Kyle's teacher praised his behavior more often. Significantly, the self-management intervention was initiated in Class Period B (bottom graph in Figure 29.7) at the teacher's request because she had noted an immediate and "dramatic change" in Kyle's performance when he began self-monitoring and recruiting teacher praise in Class Period A. This outcome is strong evidence for the social validity of the self-management intervention.

Self-Management Analogs of Negative Reinforcement

Many successful self-management interventions involve self-determined escape and avoidance contingencies analogous to negative reinforcement. Most of the case studies featured in Malott's (2012) book on self-management, *I'll Stop Procrastinating When I Get Around to It*, feature escape and avoidance contingencies in which emitting the target behavior enabled the person to avoid an aversive event. The table below provides examples:

Target Behavior/Objective	Self-Management Contingency
Make a daily journal entry of interesting things that happened so as to have events to include in a weekly letter to her parents.	Each day Kelly failed to make a journal entry, she had to do a friend's chores, including doing the dishes and laundry. (Garner, 2012)
Four $\frac{1}{2}$-hr exercise sessions (e.g., mountain bike, aerobics, strength building) per week; 3 sessions must be during the week and 1 session on the weekend.	Pin $5 bill to the corkboard on the refrigerator and give it to my roommate at the end of the week if the exercise goal remains unmet. (Haroff, 2012)
Practice guitar for half an hour each day of the week before 11:00 PM.	Do 50 sit-ups at 11:00 PM on Sundays for each day that I did not practice during the week. (Knittel, 2012)

At stickK.com individuals can design personalized "commitment contracts" in which they specify behavior change goals, set dates for completion, select referees to verify self-reports of task completion, and escrow a self-determined amount of money to lose if the terms of the contract are not met. In response to the uneasiness some people may feel about using negative reinforcement to control their behavior, Malott (2012) made the following case for building "pleasant aversive control" into self-management programs.

> Aversive control doesn't have to be aversive! . . . Here's what I think you need in order to have a pleasant aversive control procedure. You need to make sure that the aversive consequence, the penalty, is small. And you need to make sure the penalty is usually avoided—the avoidance response needs to be one that the person will readily make, most of the time, as long as the avoidance procedure is in effect.
>
> Our everyday life is full of such avoidance procedures, and yet they don't make us miserable. You don't have an anxiety attack every time you walk through a doorway, even though you might hurt yourself if you don't avoid bumping into the doorjamb. And you don't break out in a cold sweat every time you put the leftovers in the refrigerator, and thereby avoid leaving them out to spoil. So that leads us to the Self-Management Rule: Don't hesitate to use an avoidance procedure to get yourself to do something you want to do anyway. Just be sure the aversive outcome is as small as possible (but not so small it's ineffective) and the response is easy to make. (p. 80)

Self-Administered Consequences to Decrease Behavior

Self-administered consequences analogous to positive punishment or negative punishment can decrease the occurrence of undesirable behavior.

Self-Management Analogs of Positive Punishment

A person can decrease the rate of an undesired behavior by following each occurrence with the onset of painful stimulation or aversive activity. Mahoney (1971) reported a case study in which a man beleaguered by obsessive thoughts wore a heavy rubber band around his wrist. Each time he experienced an obsessive thought, he snapped the rubber band, delivering a brief, painful sensation to his wrist. A 15-year-old girl who had compulsively pulled her hair for $2\frac{1}{2}$ years, to the point of creating bald spots, also used contingent self-delivered snaps of a rubber band on her wrist to stop her habit (Mastellone, 1974). Another woman stopped her hair pulling by performing 15 sit-ups each time she pulled her hair or had the urge to do so (MacNeil & Thomas, 1976).

Self-administering a positive practice overcorrection procedure also qualifies as an example of self-administered positive punishment. Heward, Dardig, and Rossett (1979) described the case of a teenage girl who frequently said *don't* instead of *doesn't* with the third person singular (e.g., "She don't like that one.") and used this form of self-administered positive punishment to decrease the rate of her speech error. Each time the girl observed herself saying *don't* when she should have said *doesn't*, she covertly repeated the complete sentence she had just spoken 10 times in a row, using correct grammar. She wore a wrist counter that reminded her to listen to her speech and to keep track of the number of times she employed the positive practice procedure.

Self-Management Analogs of Negative Punishment

Self-administered analogs to negative punishment consist of arranging the loss of reinforcers (response cost) or denying oneself access to reinforcement for a specified period (time-out) contingent on the occurrence of the target behavior. Response cost and time-out contingencies are widely used self-management strategies. The most commonly applied self-administered response cost procedure is paying a small fine each time the target behavior occurs. In one study, smokers reduced their rate of smoking by tearing up a dollar bill each time they lit up (Axelrod, Hall, Weis, & Rohrer, 1971). Response cost procedures have also been used effectively with elementary school children who self-determined the number of tokens they should lose for inappropriate social behavior (Kaufman & O'Leary, 1972) or for poor academic work (Humphrey, Karoly, & Kirschenbaum, 1978).

James (1981) taught an 18-year-old man who had stuttered severely since the age of 6 to use a time-out from speaking procedure. Whenever he observed himself stuttering, the young man immediately stopped talking for at least 2 seconds, after which he could begin speaking again. His rate of dysfluencies decreased markedly. If talking is reinforcing, then this procedure might function as time-out (e.g., not allowing oneself to engage in a preferred activity for a period of time).

Recommendations for Self-Administered Consequences

Persons designing and implementing self-administered consequences should consider the following recommendations.

Select Small, Easy-to-Deliver Consequences

Both rewards and penalties used in self-management programs should be small and easily delivered. A common mistake in designing self-management programs is selecting consequences that are big and grand. Although a person may believe that the promise of a large reward (or threat of a severe aversive event) will motivate her to meet her self-determined performance criteria, large consequences often work against the program's success. Self-selected rewards and punishing consequences should not be costly, elaborate, time-consuming, or too severe. If they are, the person may not be able (in the case of grand rewards) or willing (in the case of severe aversive events) to deliver them immediately and consistently.

In general, it is better to use small consequences that can be obtained immediately and frequently. This is particularly important with consequences intended to function as punishers, which—to be most effective—must be delivered immediately every time the behavior targeted for reduction is emitted.

Set a Meaningful but Easy-to-Meet Criterion for Reinforcement

When designing contingencies involving self-administered consequences, a person should guard against making the same two mistakes practitioners often make when implementing reinforcement contingencies with clients: (1) setting expectations so low that improvement in the current level of performance is not necessary to obtain the self-administered reward, or (2) making the initial performance criterion too high (the more common mistake), thereby effectively programming an extinction contingency that may cause the person to give up on self-management altogether. Keys to the effectiveness of any reinforcement-based intervention are setting an initial criterion that ensures that the person's behavior makes early contact with reinforcement and that continued reinforcement requires improvements over baseline levels. The criterion-setting formulae (Heward, 1980) described in Chapter 11 provide guidelines for making those determinations.

Eliminate "Bootleg Reinforcement"

Bootleg reinforcement—access to the specified reward or to other equally reinforcing items or events without meeting the response requirements of the contingency—is a common downfall of self-management projects. A person with a comfortable supply of smuggled rewards is less likely to work hard to earn response-contingent rewards.

Bootleg reinforcement is common when people use everyday preferred activities and treats as rewards in self-management programs. Although everyday expectations and enjoyments are easy to deliver, a person may find it difficult to withhold things he is used to enjoying on a regular basis. For example, a man used to unwinding at the end of the day by watching *Baseball Tonight* with a beer and a bowl of peanuts may not be consistent in making those daily treats contingent on meeting the requirements of his self-management program.

One method for combating this form of bootleg reinforcement is to retain free access to activities or items routinely enjoyed in the past and make alternative items or activities that are a cut above the usual contingent on meeting performance criteria. For example, each time the man in the previous scenario meets his performance criteria, he could replace his everyday brand of beer with his choice of a specialty beer from a collection reserved in the back of the refrigerator (e.g., Bell's Two Hearted IPA).

If Necessary, Put Someone Else in Control of Delivering Consequences

Most ineffective self-management programs fail not because the controlling behavior is ineffective in controlling the controlled behavior, but because the contingencies that control the controlling behavior are not sufficiently strong. In other words, the person does not emit the controlling behavior consistently enough to realize its effects. What keeps a person from rationalizing that she did most of the behaviors she was supposed to and obtaining a self-determined reward anyway? What keeps a person from failing to deliver a self-determined aversive consequence? Too often, the answer to both questions is—nothing.

A person who really wants to change her behavior but has difficulty following through with delivering self-determined consequences should enlist another person to serve as performance manager. A self-manager can ensure her self-designed consequences will be administered faithfully by creating a contingency in which the consequence for failing to meet the performance criterion is both aversive to her *and* a reinforcer for the person she has asked to implement the consequence. If the first person put in charge of the contingency fails to implement it as planned, the self-manager should find another person who will do the job.

> Christie wanted to walk on her dust-gathering treadmill 20 minutes a day, 6 days a week. She tried her husband as her performance contractor, but he wasn't tough enough; he always felt sorry for her. So she fired him and hired her son; she made his bed every time she failed to do her 20 minutes, and he showed no mercy. (Malott, 2012, p. 132)

Internet-based self-deposit contracts for cigarette smoking reduction or abstinence (Dallery, Raiff, & Grabinski, 2013; Jarvis & Dallery, 2017) or those created on stickK.com ensure that self-determined consequences are carried out. Kanfer (1976) called this kind of self-management *decisional self-control*: The person makes the initial decision to alter her behavior and plans how that will be accomplished, but then turns over the procedure to a second party to avoid the possibility of not emitting the controlling response. Kanfer made a distinction between decisional self-control and protracted self-control, in which a person consistently engages in self-deprivation to effect the desired behavior change. Bellack and Hersen (1977) stated that decisional self-control "is generally considered to be less desirable than protracted self-control, as it does not provide the individual with an enduring skill or resource" (p. 111).

We disagree that a self-management program involving the help of other people is less desirable than one in which the self-manager does everything. First, a self-management program

in which the contingencies are turned over to someone else may be more effective than trying to "go it alone" because the other person is more consistent in applying the consequences. In addition, as a result of experiencing a successful self-management program in which he has chosen the target behavior, set performance criteria, determined a self-monitoring/self-evaluation system, and arranged to have someone else administer self-designed consequences, a person has acquired a considerable repertoire of self-management skills for future use.

Keep It Simple

A person should not create elaborate self-management contingencies if they are not needed. The same general rule that applies to behavior change programs designed on behalf of others—employ the least complicated and intrusive, yet effective, intervention—also applies to self-management programs.

OTHER SELF-MANAGEMENT TACTICS

Other self-management strategies used by behavior analysts are not so easily classified according to the four-term contingency. They include self-instruction, habit reversal, self-directed systematic desensitization, and massed practice.

Self-Instruction

People talk to themselves all the time, offering encouragement (e.g., "I can do this; I've done it before"), congratulations (e.g., "Great shot, Daryl! You just crushed that 5-iron!"), and admonishment (e.g., "Don't say that anymore; you hurt her feelings") for their behavior, as well as specific instructions (e.g., "Pull the bottom rope through the middle"). Such self-statements can function as controlling responses—verbal mediators—that affect the occurrence of other behaviors. **Self-instruction** consists of self-generated verbal responses, covert or overt, that function as response prompts for a desired behavior. As a self-management tactic, self-instructions are often used to guide oneself through a behavior chain or sequence of tasks.

Bornstein and Quevillon (1976) conducted a study frequently cited as evidence of the positive and lasting effects of self-instruction. They taught three hyperactive preschool boys a series of four types of self-instruction designed to keep them on task with classroom activities:

1. Questions about the assigned task (e.g., "What does the teacher want me to do?")
2. Answers to the self-directed questions (e.g., "I'm supposed to copy that picture.")
3. Verbalizations to guide the child through the task at hand (e.g., "OK, first I draw a line through here.")
4. Self-reinforcement (e.g., "I really did that one well.")

During a 2-hr session, the children were taught to use self-instructions incorporating a sequence of training steps originally developed by Meichenbaum and Goodman (1971):

1. The experimenter modeled the task while talking aloud to himself.
2. The child performed the task while the experimenter provided the verbal instructions.
3. The child performed the task while talking aloud to himself with the experimenter whispering the instructions softly.
4. The child performed the task while whispering softly to himself with the experimenter moving his lips but making no sound.
5. The child performed the task while making lip movements but no sound.
6. The child performed the task while guiding his performance with covert instructions. (adapted from p. 117)

During the training session, a variety of classroom tasks were used, ranging from simple motor tasks such as copying lines and figures to more complex tasks such as block design and grouping tasks. The children showed a marked increase in on-task behavior immediately after receiving self-instruction training, and their improved behavior was maintained over a considerable period. The authors suggested that the generalization obtained from the training setting to the classroom could have resulted from telling the children during training to imagine they were working with their teacher, not the experimenter. The authors hypothesized that a behavioral trapping phenomenon (Baer & Wolf, 1970) may have been responsible for the maintenance of on-task behavior; that is, the self-instructions may have initially produced better behavior, which in turn produced teacher attention that maintained the on-task behavior.

Although some studies evaluating self-instruction failed to reproduce Bornstein and Quevillon's (1976) impressive results (e.g. Billings & Wasik, 1985; Friedling & O'Leary, 1979), other studies have yielded generally encouraging results (Burgio, Whitman, & Johnson, 1980; Hughes, 1992; Kosiewicz, Hallahan, Lloyd, & Graves, 1982). Self-instruction training has increased the rate of high school students' initiating conversations with familiar and unfamiliar peers (Hughes, Harmer, Killian, & Niarhos, 1995; see Figure 30.5).

Employees with disabilities have learned to self-manage their work performance by providing their own verbal prompts and self-instructions (Hughes, 1997). For example, Salend, Ellis, and Reynolds (1989) used a self-instruction strategy to teach four adults with severe cognitive disabilities to "talk while you work." Productivity increased dramatically and error rates decreased when the women verbalized to themselves, "Comb up, comb down, comb in bag, bag in box" while packaging combs in plastic bags. Hughes and Rusch (1989) taught two supported employees working at a janitorial supply company how to solve problems by using a self-instruction procedure consisting of four statements:

1. Statement of the problem (e.g., "Tape empty")
2. Statement of the response needed to solve the problem (e.g., "Need more tape")
3. Self-report (e.g., "Fixed it")
4. Self-reinforcement (e.g., "Good")

O'Leary and Dubey (1979) summarized their review of self-instruction training by suggesting four factors that appear to influence its effectiveness with children.

> Self-instructions appear to be effective self-controlling procedures if the children actually implement the instructional procedure, if the children use them [the self-instructions] to influence behavior at which they are skilled, if children have been reinforced for adhering to their self-instructions in the past, and if the focus of the instructions is the behavior most subject to consequences. (p. 451)

Habit Reversal

In his discussion of self-control, Skinner (1953) included "doing something else" as a self-management tactic. In an interesting application of "doing something else," Robin, Schneider, and Dolnick (1976) taught 11 primary-age children with emotional and behavioral disorders to control their aggressive behaviors by using the turtle technique: The children pulled their arms and legs close to their bodies, put their heads down on their desks, relaxed their muscles, and imagined they were turtles. The children were taught to use the turtle response whenever they believed an aggressive exchange with someone else was about to take place, when they were angry with themselves and felt they were about to have a tantrum, or when the teacher or a classmate called out, "Turtle!"

Azrin and Nunn (1973) developed an intervention they called **habit reversal**, in which clients are taught to self-monitor their nervous habits and interrupt the behavior chain as early as possible by engaging in behavior incompatible with the problem behavior (i.e., doing something else). For example, when a nail biter observes herself beginning to bite her fingernails, she might squeeze her hand into a tight fist for 2 or 3 minutes (Azrin, Nunn, & Frantz, 1980) or sit on her hands (Long, Miltenberger, Ellingson, & Ott, 1999). Habit reversal is typically implemented as a treatment package that includes self-awareness training involving response detection and procedures for identifying events that precede and trigger the response and competing response training. Motivation techniques including self-administered consequences, social support systems, and procedures for promoting the generalization and maintenance of treatment gains may also be included. Habit reversal has proven an effective self-management tactic for a wide variety of problem behaviors (Miltenberger, Fuqua, & Woods, 1998).

Mancuso and Miltenberger (2016) conducted a study using habit reversal with six female college students seeking to improve their public speaking skills. The students filled pauses by uttering nonsense syllables such as "uh," "um," or "er"; tongue clicking (pressing the tongue against the roof of the mouth and releasing the pressure to make an audible "tsk" or click sound); and interjecting the word "like." These target behaviors were recorded during 3- to 5-min speeches throughout the study. Each session the researcher randomly selected 2 topics from a list of 25 (e.g., my favorite movie, my first job) and instructed the participant to choose 1. The participant was then given 10 minutes to prepare an outline for a 5-min speech. Participants were allowed to use their outlines during their speeches.

Intervention consisted of one-on-one habit reversal training sessions with the researcher. Response detection began with each participant identifying occurrences of the target behaviors in 3-min video clips of her baseline speeches. The participant then practiced detecting the target behaviors during live speeches by raising her right hand each time she engaged in one of the behaviors and her left hand when becoming aware that she was about to emit one of the behaviors. Response detection training ended when the participant identified 100% of target behavior occurrences in one speech or 85% of the occurrences in two consecutive speeches.

Next, each participant practiced emitting competing responses for each target behavior: for "uh," "um," or "er," a 3-sec silent pause; for tongue clicking, placing the tongue against the inside of the bottom teeth for 3 seconds; for interjecting "like," beginning the sentence again without "like." Competing response training concluded when the participant achieved an 80% reduction in the target behavior from her baseline mean during a speech.

Habit reversal training resulted in an immediate and lasting decrease in filled pauses by the participants (see Figure 29.8). The participants emitted moderate to high rates of filled pauses during baseline (mean across participants of 7.4 responses per minute). Following habit reversal training, the mean rate of filled pauses by the participants was 1.4 responses per minute. Each participant maintained her improved performance in a follow-up speech 2 to 5 weeks later.

Self-Directed Systematic Desensitization

Systematic desensitization is a widely used behavior therapy treatment for anxieties, fears, and phobias that features the self-management strategy of engaging in an alternative behavior (i.e., doing something else). Originally developed by Wolpe (1958, 1973), **systematic desensitization** involves substituting one behavior, generally muscle relaxation, for the unwanted behavior—the fear and anxiety. The client develops a hierarchy of situations from the least to the most fearful and then learns to relax while imagining these anxiety-producing situations, first the least fearful situation, then the next fearful one, and so on. Figure 29.9 shows an anxiety-stimulus hierarchy that a person might develop in attempting to control a fear of cats. When a person is able to go completely through his hierarchy, imagining each scene in detail while maintaining deep relaxation and feeling no anxiety, he begins to expose himself gradually to real-life situations.

Detailed procedures for achieving deep muscle relaxation, constructing and validating a hierarchy of anxiety- or fear-producing situations, and implementing a self-directed systematic desensitization program can be found in Martin and Pear (2015) and Wenrich, Dawley, and General (1976).

Massed Practice

Forcing oneself to perform an undesired behavior again and again, a technique called **massed practice**, will sometimes

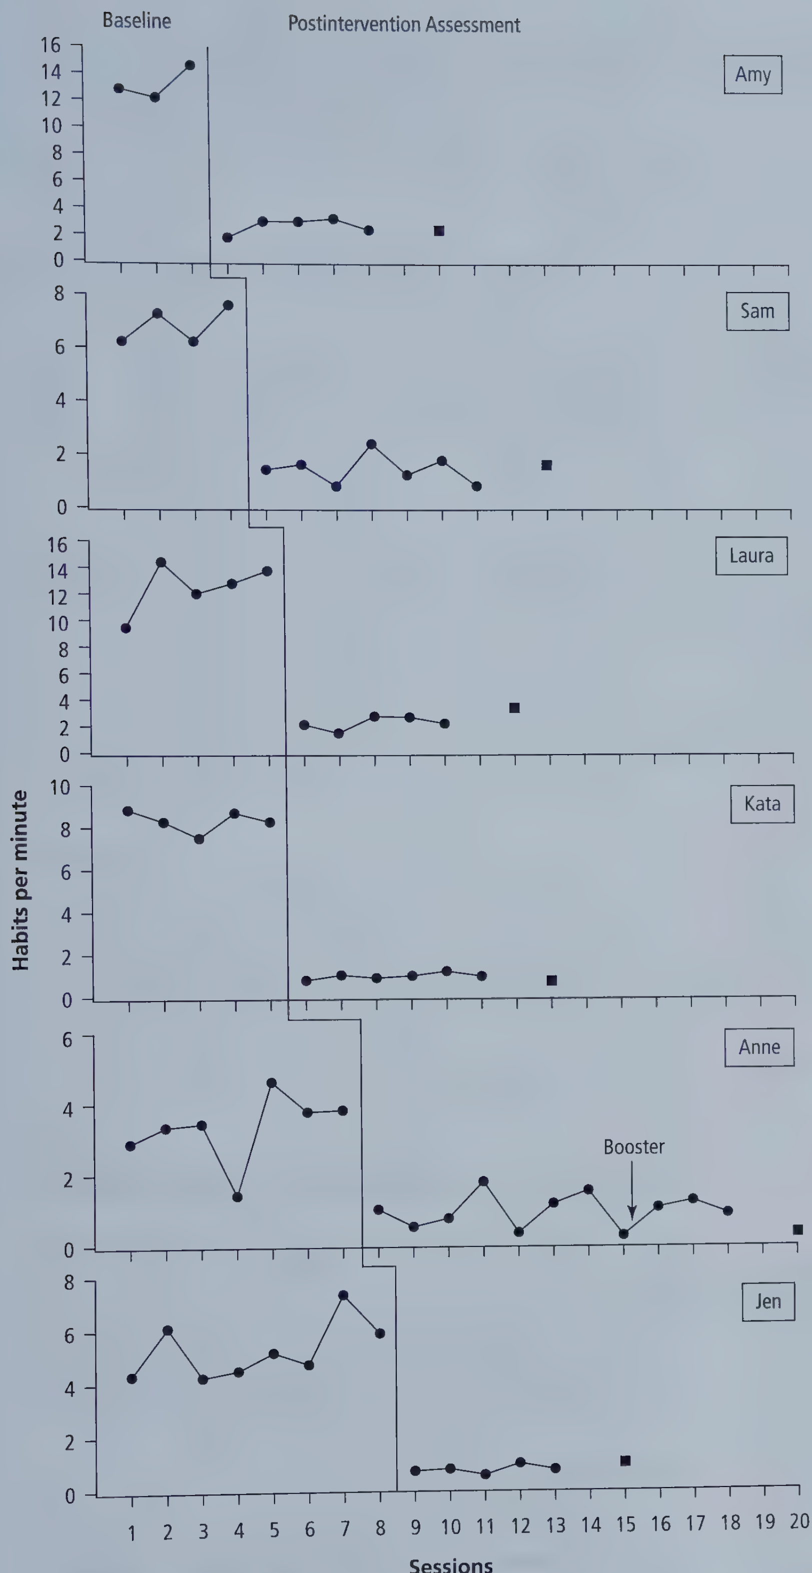

Figure 29.8 Effects of habit reversal training on the rate of filled pauses during speeches by six university students during baseline and after habit reversal training. The downward arrow represents sessions conducted after Anne received a booster session. Square data points represent 2- to 5-week follow-up speeches.

From "Using Habit Reversal to Decrease Filled Pauses in Public Speaking." by C. Mancuso and R. G. Miltenberger, 2016, *Journal of Applied Behavior Analysis*, *49*, p. 191. Copyright 2016 by the Society for the Experimental Analysis of Behavior, Inc. Reprinted by Permission.

decrease the future occurrences of the behavior. Wolff (1977) reported an interesting case of this form of treatment by a 20-year-old woman who engaged in a compulsive, ritualized routine of 13 specific security checks every time she entered her apartment (e.g., looking under beds, checking the closets, looking in the kitchen). She began her program by deliberately going through the 13 steps in an exact order and then repeating the complete ritual 4 more times. After doing this for 1 week, she permitted herself to check the apartment if she wanted to but made herself go through the entire routine 5 times whenever she did any checking at all. She soon stopped performing her compulsive checking behavior.

Figure 29.9 Sequence of imaginary scenes concerning fear of cats that could be used for systematic self-desensitization.

Directions

1. You're sitting in a comfortable chair in the safety of your home watching TV.
2. You're watching a commercial for cat food—no cat is visible.
3. The commercial continues and a cat is now eating the food.
4. A man is now petting the cat.
5. A man is holding the cat and fondling it.
6. A woman is holding the cat, and the cat is licking her hands and face.
7. You're looking out the window of your home and you see a cat on the lawn across the street.
8. You're sitting in front of your house, and you see a cat walk by on the sidewalk across the street.
9. You're sitting in your yard, and you see a cat walk by on your sidewalk.
10. A cat walks within 15 feet of you.
11. A friend of yours picks the cat up and plays with it.
12. Your friend is 10 feet away from you, and the cat is licking his face.
13. Your friend comes within 5 feet of you while he's holding the cat.
14. Your friend stands 2 feet away and plays with the cat.
15. Your friend asks if you'd like to pet the cat.
16. Your friend reaches out and offers you the cat.
17. He puts the cat on the ground, and it walks over to you.
18. The cat rubs up against your leg.
19. The cat walks between your legs purring.
20. You reach down and touch the cat.
21. You pet the cat.
22. You pick up the cat and pet it. (p. 71)

SUGGESTIONS FOR EFFECTIVE SELF-MANAGEMENT PROGRAMS

Incorporating the suggestions that follow into the design and implementation of self-management programs should increase the likelihood of success. Although none of these guidelines has been rigorously examined through experimental analyses—research on self-management has a long way to go—each suggestion is consistent with procedures proven effective in other applications of behavior analysis and with "best practices" commonly recommended in the self-management literature (e.g., Malott, 2012; Martin & Pear, 2015; Watson & Tharp, 2014).

1. Specify a goal and define the behavior to be changed.
2. Self-monitor the behavior.
3. Contrive contingencies that will compete with natural contingencies.
4. Go public with your commitment to change your behavior.
5. Get a self-management partner.
6. Continually evaluate your self-management program and redesign it as necessary.

Specify a Goal and Define the Target Behavior

A self-management program begins with identifying a personal goal or objective and the specific behavior changes necessary to accomplish that goal or objective. A person can use most of the questions and issues that practitioners should consider when selecting target behaviors for students or clients (see Chapter 3) to assess the social significance and prioritize the importance of a list of self-determined target behavior changes.

Self-Monitor the Behavior

A person should begin self-monitoring as soon as he has defined the target behavior. Self-monitoring prior to implementing any other form of intervention yields the same benefits as does taking baseline data described in Chapter 7.

1. Self-monitored baseline data provide information about antecedent-behavior-consequent correlations that may be helpful in designing an effective intervention.
2. Self-monitored baseline data provide guidance for setting initial performance criteria for self-administered consequences.

3. Self-monitored baseline data provide an objective basis for evaluating the effects of any subsequent interventions.

Another reason to begin self-monitoring as soon as possible without using additional self-management tactics is that the desired improvement in behavior may be achieved by self-monitoring alone.

Contrive Contingencies That Will Compete with Ineffective Natural Contingencies

When self-monitoring alone does not result in the desired behavior change, the next step is designing a contrived contingency to compete with the natural contingencies. A person who implements a contingency that provides immediate, definite consequences for each occurrence (or perhaps, nonoccurrence) of the target behavior greatly increases the probability of obtaining a previously elusive self-management goal. For example, a smoker who self-records and reports each cigarette smoked to his self-management partner, who provides contingent praise, rewards, and penalties, has arranged immediate, frequent, and more effective consequences for reducing his smoking behavior than those provided by the natural contingency: the threat of emphysema and death by lung cancer in the future, with neither outcome becoming appreciably more immediate or likely from one cigarette to the next.

Go Public

Publicly sharing the intentions of a self-management effort may enhance its effectiveness. When a person shares a goal or makes a prediction to others about her future behavior, she has arranged potential consequences—praise or condemnation—for her success or failure in meeting that goal. A person should state in specific terms what she intends to do and her deadline for completing it. Taking the idea of public commitment a step further, consider the powerful potential of public posting (e.g., an untenured junior faculty member could post a chart of her writing where her department chair or dean could see and comment on it).

Malott (1981) called this the "public spotlight principle of self-management."

> A public statement of goals improves performance. But just how do the social contingencies engaged by public commitment produce change? They increase the rewarding value of success and the aversive value of failure, I presume. But those outcomes are probably too delayed to directly reinforce problem solving. Instead they must be part of the rules the student self-states at crucial times: "If I don't make my goal, I'll look like a fool; but if I do make it, I'll look pretty cool." Such rules then function as cues for immediate self-reinforcement of on-task behavior and self-punishment of off-task behavior. (Volume II, No. 18, p. 5)

Skinner (1953) also theorized about the principles of behavior that operate when a person shares a self-management goal with important others.

> By making it in the presence of people who supply aversive stimulation when a prediction is not fulfilled, we arrange consequences which are likely to strengthen the behavior resolved upon. Only by behaving as predicted can we escape the aversive consequences of breaking our resolution. (p. 237)

Get a Self-Management Partner

Setting up a self-management exchange is a good way to involve another person whose differential feedback about how a self-management project is going can be effective as a behavioral consequence. Two people, each of whom has a long-range goal or a regular series of tasks to do, agree to interact with each other—in person or by phone, text, e-mail, or social media—on a daily or weekly basis, as determined by their schedules, preferences, the target behaviors, and each person's progress. They share their self-monitoring data and exchange verbal praise or admonishments and perhaps even more tangible consequences contingent on performance. Malott (1981) reported a successful self-management exchange in which he and a colleague paid each other \$1 every time either person failed to complete any one of a series of self-determined daily exercise, housekeeping, and writing tasks. Each morning they spoke on the telephone and reported their performance during the previous 24 hours.

To help themselves and each other study for exams and complete research and writing tasks, a group of doctoral students created a self-management exchange they called the Dissertation Club (Ferreri et al., 2006). At weekly meetings, each group member reported data on the "scholarly behaviors" she had targeted (e.g., graphs of words written each day or number of hours studied). Group members provided social support to one another in the form of encouragement to continue working hard and praise for accomplishments, served as behavioral consultants to one another on the design of self-management interventions, and sometimes administered rewards and fines to one another. All six members of the group wrote and successfully defended their dissertations within the time lines they had set.

Continually Evaluate and Redesign Program as Needed

> *The biggest problem with self-management . . . is that the systems are liable to gradually deteriorate . . . So, you must always be on top of it. And you must be prepared with duct tape and bubble gum to stick the system back together.*
>
> —R. W. Malott (2012, p. 31)

Most self-management programs embody a pragmatic, data-based approach to personal problem solving more than rigorous research with an emphasis on experimental analysis and control. Like researchers, however, self-managers should be guided by the data. If the data show the program is not working satisfactorily, the intervention should be redesigned.

People who have learned to define, observe, record, and graph their own behavior can evaluate their self-management efforts with self-experiments. A simple A-B design (Chapter 7) provides a straightforward accounting of the results in a before-and-after fashion and is usually sufficient for self-evaluation.

Experimentally determining functional relations between self-managed interventions and their effects, though valuable, usually takes a back seat to the pragmatic goal of changing one's behavior. However, the changing criterion design (Chapter 9) lends itself nicely not only to the stepwise increments in performance that are often a part of improving personal performance, but also to a clearer demonstration and understanding of the relation between the intervention and changes in the target behavior.

In addition to data-based evaluation, people should judge the social validity of their self-management projects (Wolf, 1978). Practitioners teaching self-management to others can help their clients assess the social validity of their self-management efforts by providing checklists of questions covering topics such as how practical their intervention was, whether they believed their self-management program affected their behavior in any unmeasured ways, and whether they enjoyed the project.

One of the more important aspects of social validity for any behavior change program is the extent to which the results—measured changes in the target behavior—actually make a difference in the lives of the participants. One approach to assessing the social validity of the results of a self-management program is to collect data on what Malott (2012) called *benefit measures*. For example, a person might measure:

- Number of pounds lost as a benefit measure of eating less or exercising more
- Improved lung capacity (peak airflow volume measured as cubic centimeters per second on an inexpensive device available at many pharmacies) as an outcome of reducing the number of cigarettes smoked
- Decrease in time it takes to run a mile as a benefit of number of miles run each day
- Lower resting heart rate and faster recovery time as a benefit of aerobic exercise
- Higher scores on foreign language practice exams as an outcome of studying

In addition to assessing the social validity of self-management interventions, the positive results of benefit measures may serve as consequences that reward and strengthen continued adherence to self-management.

Box 29.2: "Take a Load Off Me" describes a self-management weight loss program that incorporated many of the tactics and suggestions described in this chapter.

BEHAVIOR CHANGES BEHAVIOR

Referring to a book on self-management he authored for a popular audience, Epstein (1997) wrote:

> A young man whose life is in disarray (he smokes, drinks, overeats, loses things, procrastinates, and so on) seeks advice from his parents, teachers, and friends, but no one can help. Then the young man remembers his Uncle Fred (modeled shamelessly after Fred Skinner), whose life always seemed to be in perfect harmony. In a series of visits, Uncle Fred reveals to him the three "secrets" of self-management, all *Ms*: *Modify your environment, monitor your behaviors*, and *make commitments*. Fred also reveals and explains the "self-management principle": *Behavior changes behavior*. After each visit, the young man tries out a new technique, and his life is changed radically for the better. In one scene, he sees a classroom of remarkably creative and insightful children who have been trained in self-management techniques in a public school. It is fiction, of course, but the technology is well established and the possibilities are well within reach. (p. 563, emphasis in original)

Building upon Skinner's (1953) conceptual analysis of self-control, applied behavior analysts have developed numerous self-management tactics and methods for teaching learners with diverse abilities how to apply them. Underlying all of these efforts and findings is the simple, yet profound principle that behavior changes behavior.

BOX 29.2

Take a Load Off Me: A Self-Managed Weight Loss Program

Joe was a 63-year-old whose doctor had recently told him that the 195 pounds on his 5-foot 11-inch frame must be reduced to 175 pounds or he would likely experience serious health problems. Although Joe got regular physical exercise by keeping up the lawn and garden, cutting and hauling firewood, feeding the rabbits, and doing other chores that come with maintaining a farmhouse, his prodigious appetite—long considered one of the "best in the county"—had caught up with him. His doctor's warning and the recent death of a high school classmate scared Joe enough to sit down with his son and plan a self-management weight-loss program.

Joe's program was a package intervention that included antecedent-based tactics, self-monitoring, self-evaluation, contingency contracting, self-selected and self-administered consequences, and contingency management by significant others.

Goal

To reduce the current weight of 195 pounds to 175 pounds at a rate of 1 pound per week.

Behavior Change Needed to Achieve Goal

Reduce eating to a maximum 2100 calories per day.

Rules and Procedures

1. Mount the bathroom scale each morning before dressing or eating and chart the weight on "Joe's Weight" graph taped to the bathroom mirror.
2. Carry a notepad, pencil, and calorie counter in a pocket throughout the day and record the type and amount of *all* food and liquid (other than water) *immediately* after consumption.

3. Before going to bed each night, add the total calories consumed during the day and chart that number on "Joe's Eating" graph taped to the bathroom mirror.
4. *Do not waiver* from Steps 1–3, regardless of weight loss or lack of weight loss.

Immediate Contingencies/Consequences

- The calorie counter, notepad, and pencil in the pocket provide continuously available response prompts.
- Recording all food and drink consumed provides an immediate consequence.
- When you have not eaten any food you thought about eating, put a star on your notepad and give self-praise ("Way to go, Joe!").

Daily Contingencies/Consequences

- If the calories consumed during the day do not exceed the 2100 criterion, put 50 cents in "Joe's Garden Jar."
- If total calories exceed the criterion, remove $1.00 from "Joe's Garden Jar."
- For each 3 days in a row that you meet the calorie criterion, add a bonus of 50 cents to "Joe's Garden Jar."
- Have Helen initial your contract each day that you meet the calorie criterion.

Weekly Contingencies/Consequences

- Each Sunday night, write the calories consumed each day for the previous week on one of the predated, addressed, and stamped postcards. Helen will verify your self-report by initialing the postcard and mailing it to Bill and Jill on Monday.
- Each Monday, if total calories consumed met the criterion for at least 6 of the past 7 days, obtain an item or activity from "Joe's Reward Menu."

Intermediate Contingencies/Consequences

- Eat within the daily calorie limit often enough and there will be sufficient money in "Joe's Garden Jar" to buy seeds and plants for the spring vegetable garden.
- If your weight during the May visit to Ohio represents a loss of at least 1 pound per week, be a guest of honor at a restaurant of your choice.

Long-term Consequences

- Feel better.
- Look better.
- Be healthier.
- Live longer.

Results

Joe often struggled with the rules and procedures, but he stuck with his self-management program and lost 22 pounds (achieving a weight of 173) in 16 weeks. Joe lived 30 active years following his adventure in self-management. He retained his weight at 175 pounds and enjoyed gardening, singing in a barbershop choir, and listening to the Cubs on the radio.

SUMMARY

The "Self" as Behavior Controller

1. We tend to assign causal status to events that immediately precede behavior, and when causal variables are not readily apparent in the immediate, surrounding environment, the tendency to turn to internal causes is strong.

2. Hypothetical constructs such as willpower and drive are explanatory fictions that bring us no closer to understanding the behaviors they claim to explain and lead to circular reasoning.

3. Skinner (1953) conceptualized self-control as a two-response phenomenon: The *controlling response* affects variables in such a way as to change the probability of the other, the *controlled response*.

Self-Management Defined

4. We define self-management as the personal application of behavior change tactics that produces a desired change in behavior.

5. Self-management is a relative concept. A behavior change program may entail a small degree of self-management or be totally conceived, designed, and implemented by the person.

6. Although *self-control* and *self-management* often appear interchangeably in the behavioral literature, we recommend that *self-management* be used in reference to a person acting in some way *in order to* change his subsequent behavior. Three reasons for this recommendation are as follows:
   - Self-control implies that the ultimate control of behavior lies within the person, but the causal factors for "self-control" are to be found in a person's experiences with his environment.
   - Self-control as a causal factor can serve as an explanatory fiction suggesting "a [separate] self inside or [that there is] a self inside controlling external behavior" (Baum, 2017, p. 167).
   - Laypeople and behaviorists alike use self-control to refer to a person's ability to "delay gratification" by responding to achieve a delayed, but larger or higher quality, reward instead of acting to obtain an immediate, less valuable reward.

7. People discount the value of delayed rewards; the greater the delay, the less value or influence the reward has on current behavior. Behavior analysts call this phenomenon delay discounting (or *temporal discounting*).

Applications, Advantages, and Benefits of Self-Management

8. Four uses of self-management are to
   - live a more effective and efficient daily life,
   - break bad habits and acquire good ones,
   - accomplish difficult tasks, and
   - achieve personal lifestyle goals.
9. Advantages and benefits of learning and teaching self-management skills include the following:
   - Self-management can influence behaviors not accessible to external change agents.
   - External change agents often miss important instances of behavior.
   - Self-management can promote the generalization and maintenance of behavior change.
   - A small repertoire of self-management skills can control many behaviors.
   - People with diverse abilities can learn self-management skills.
   - Some people perform better under self-selected tasks and performance criteria.
   - People with good self-management skills contribute to more efficient and effective group environments.
   - Teaching students self-management skills provides meaningful practice for other areas of the curriculum.
   - Self-management is an ultimate goal of education.
   - Self-management benefits society.
   - Self-management helps a person feel free.
   - Self-management feels good.

Antecedent-based Self-Management Tactics

10. Antecedent-based self-management tactics feature the manipulation of events or stimuli antecedent to the target (controlled) behavior, such as the following:
    - Manipulating motivating operations to make a desired (or undesired) behavior more (or less) likely
    - Providing response prompts
    - Performing the initial steps of a behavior chain to ensure being confronted later with a discriminative stimulus that will evoke the desired behavior
    - Removing the materials required for an undesired behavior
    - Limiting an undesired behavior to restricted stimulus conditions
    - Dedicating a specific environment for a desired behavior

Self-Monitoring

11. Self-monitoring is a procedure whereby a person observes and responds to, usually by recording, the behavior he is trying to change.
12. Originally developed as a method of clinical assessment for collecting data on behaviors that only the client could observe, self-monitoring evolved into the most widely used and studied self-management strategy because it often results in desired behavior change.
13. Self-monitoring is often combined with goal setting and self-evaluation. A person using self-evaluation compares her performance with a predetermined goal or standard.
14. Self-monitoring is often part of an intervention that includes reinforcement for meeting either self- or teacher-selected goals.
15. It is difficult to determine exactly how self-monitoring works because the procedure necessarily includes, and is therefore confounded by, private events (covert verbal behavior); it often includes either explicit or implicit contingencies of reinforcement.
16. Children can be taught to self-monitor and self-record their behavior accurately by means of a faded matching technique, in which the child is rewarded initially for producing data that match the teacher's or parent's data. Over time the child is required to match the adult's record less often, eventually monitoring the behavior independently.
17. Accuracy of self-monitoring is neither necessary nor sufficient to achieve improvement in the behavior being monitored.
18. Suggested guidelines for self-monitoring are as follows:
    - Provide materials that make self-monitoring easy.
    - Provide supplementary cues or prompts.
    - Self-monitor the most important dimension of the target behavior.
    - Self-monitor early and often, but do not interrupt the flow of a desired behavior targeted for increase.
    - Reinforce accurate self-monitoring.

Self-Administered Consequences

19. As a technical term, *self-reinforcement* (as also, self-punishment) is a misnomer. Although behavior can be changed by self-administered consequences, the variables influencing the controlling response make such self-management tactics more than a straightforward application of operant reinforcement.
20. Self-administered contingencies analogous to positive and negative reinforcement and positive and negative punishment can be incorporated into self-management programs.
21. When designing self-management programs involving self-administered consequences, a person should:
    - Select small, easy-to-deliver consequences.
    - Set a meaningful but easy-to-meet criterion for reinforcement.
    - Eliminate "bootleg reinforcement."
    - If necessary, put someone else in control of delivery consequences.
    - Use the least complicated and intrusive contingencies that will be effective.

Other Self-Management Tactics

22. Self-instruction (talking to oneself) can function as a controlling response (verbal mediator) that affects the occurrence of other behaviors.

23. Habit reversal is a multiple-component treatment package in which clients are taught to self-monitor their unwanted habits and interrupt the behavior chain as early as possible by engaging in a behavior incompatible with the problem behavior.

24. Systematic desensitization is a behavior therapy treatment for anxieties, fears, and phobias that involves substituting one behavior, generally muscle relaxation, for the unwanted behavior—the fear and anxiety. Self-directed systematic desensitization involves developing a hierarchy of situations from the least to the most fearful and then learning to relax while imagining these anxiety-producing situations, first the least fearful situation, then the next fearful one, and so on.

25. Massed practice, forcing oneself to perform an undesired behavior again and again, can decrease future occurrences of the behavior.

Suggestions for Effective Self-Management Programs

26. Following are six steps in designing and implementing a self-management program:

Step **1:** Specify a goal and define the behavior to be changed.

Step **2:** Self-monitor the behavior.

Step **3:** Create contingencies that will compete with natural contingencies.

Step **4:** Go public with the commitment to change behavior.

Step **5:** Get a self-management partner.

Step **6:** Continually evaluate and redesign the program as needed.

Behavior Changes Behavior

27. The most fundamental principle of self-management is that behavior changes behavior.

KEY TERMS

habit reversal
massed practice
self-control
self-evaluation
self-instruction
self-management
self-monitoring
systematic desensitization

MULTIPLE-CHOICE QUESTIONS

1. The personal application of behavior change tactics that produces a desired change in behavior is:

a. Self-management

b. Managing behaviors

c. Behavior management

d. Behavior modification

Hint: (See "The 'Self' as Controller of Behavior")

2. Self-management can help individuals to:

a. Break bad habits and replace with good ones

b. Accomplish difficult tasks

c. Achieve personal goals

d. All of these

Hint: (See "Applications, Advantages, and Benefits of Self-Management")

3. Limiting an undesired behavior to restructure stimulus conditions is

a. A consequent self-management tactic

b. An antecedent-based self-management tactic

c. Always used when possible to produce an effective self-management program

d. None of these

Hint: (See "Antecedent-Based Self-Management Tactics")

4. Self-monitoring is best defined as:

a. A procedure whereby persons observe their own behavior and record only the occurrence of the target behavior

b. A procedure whereby persons observe the behavior of someone else and systematically record the occurrence or nonoccurrence of the target behavior

c. A procedure whereby persons observe their behavior systematically and record the occurrence or nonoccurrence of the target behavior

d. A procedure whereby persons observe their behavior and someone else systematically records the occurrence or nonoccurrence of the target behavior.

Hint: (See "Self-Monitoring")

5. Suggested guidelines for effective and efficient self-monitoring include:

a. Make materials cumbersome and sophisticated

b. Never provide supplementary cues or prompts; this will make the individual become dependent on the prompts or cues rather than the target behavior

c. Self-monitor the most important dimension of the target behavior

d. Do not reinforce accurate self-monitoring

Hint: (See "Self-Monitoring")

6. Self-administered consequences that increase desired behavior include:
   a. Self-management analogs of positive reinforcement
   b. Self-management analogs of positive punishment
   c. Self-management analogs of negative punishment
   d. None of these
   Hint: (See "Self-Administered Consequences")
7. If you wanted to decrease a desired behavior, what type of self-administered consequence would be most useful?
   a. Self-management analogs of positive reinforcement
   b. Self-management analogs of negative reinforcement
   c. Self-management analogs of positive punishment
   d. None of these
   Hint: (See "Self-Administered Consequences")
8. A type of self-management tactic that typically involves the use of self-awareness training, competing response training, and motivation techniques is:
   a. Self-Instruction
   b. Habit Reversal
   c. Massed Practice
   d. None of these
   Hint: (See "Other Self-Management Tactics")
9. This type of self-management tactic involves self-generated verbal responses, covert or overt, that function as response prompts for a desired behavior.
   a. Self-instruction
   b. Self-directed systematic desensitization
   c. Habit reversal
   d. None of these
   Hint: (See "Other Self-Management Tactics")
10. The first step in conducting an effective self-management program is:
    a. Begin self-monitoring the behavior
    b. Contrive contingencies that will compete with natural contingencies
    c. Continually evaluate your self-management program and redesign it as necessary
    d. Specify a goal and define the behavior to be changed
    Hint: (See "Suggestions for Conducting an Effective Self-Management Program")

ESSAY-TYPE QUESTIONS

1. What is self-management and what are three of its potential advantages or benefits?
   Hint: (See "The 'Self' as a Controller of Behavior" and "Applications, Advantages, and Benefits of Self-Management")
2. What is self-monitoring and what procedures promote its effectiveness?
   Hint: (See "Self-Monitoring")
3. What are self-administered consequences and what is an example of one that would increase a desired or decrease an undesired behavior?
   Hint: (See "Self-Administered Consequences")
4. Name and describe an additional self-management tactic that is discussed within the text.
   Hint: (See "Other Self-Management Tactics")
5. List and discuss the steps for conducting an effective self-management program.
   Hint: (See "Suggestions for Conducting an Effective Self-Management Program")

NOTES

1. Explanatory fictions and circular reasoning are discussed in Chapters 1 and 11.
2. There is also nothing new about self-management. As Epstein (1997) noted, many self-control techniques outlined by Skinner were described by ancient Greek and Roman philosophers and have appeared in the teachings of organized religions for millennia (cf. Bolin & Goldberg, 1979; Shimmel, 1977, 1979).
3. For a variety of conceptual analyses of self-control/self-management from a behavioral perspective, see Brigham (1983), Catania (1975, 2013), Goldiamond (1976), Hughes and Lloyd (1993), Kanfer and Karoly (1972), Malott (1984, 1989, 2005a, b), Moore (2015), Rachlin (1995, 2016), and Watson and Tharp (2014).
4. In early biological theory, *homunculus* was a fully formed human being thought to exist inside an egg or spermatozoon.
5. Generalized behavior change is a defining goal of applied behavior analysis and the focus of Chapter 30.
6. Motivating operations are described in detail in Chapter 16.
7. The critical importance of immediacy in reinforcement is discussed in Chapter 11.

PART 12

Promoting Generalized Behavior Change

It is one thing to implement interventions that change behavior; it is quite another to extend those behavior changes through time, across settings, or to new behaviors. Practitioners face no more challenging or important task than that of designing, implementing, and evaluating interventions that produce behavior changes that continue after the intervention is terminated, appear in relevant environments beyond the training setting, and engender related behaviors that were not taught directly. Chapter 30 defines the major types of generalized behavior change and describes strategies and tactics applied behavior analysts use to achieve them.

CHAPTER 30

Generalization and Maintenance of Behavior Change

LEARNING OBJECTIVES

- Define and provide examples of the different basic forms of generalized behavior change.
- Define and provide examples of the different undesirable types of generalized behavior change.
- Discuss planning techniques for generalized behavior change.
- List and discuss strategies and tactics for promoting generalized behavior change.
- Discuss how to modify and terminate successful interventions.
- Name and discuss the guiding principles for promoting generalized outcomes.

Sherry's teacher implemented an intervention that taught her to complete each part of multiple-part, in-school assignments before submitting them and beginning another activity. Now, 3 weeks after the program ended, most of the work Sherry submits as "finished" is incomplete and her stick-with-a-task-until-it's-finished behavior is as poor as it was before the intervention began.

Ricardo has just begun his first competitive job working as a copy machine operator in a downtown business office. In spite of his long history of distractibility and poor endurance, Ricardo had learned to work independently for several hours at a time in the copy room at the vocational training center. His employer, however, is complaining that Ricardo frequently stops working after a few minutes to seek attention from others. Ricardo may soon lose his job.

Brian is a 10-year-old boy diagnosed with autism. In an effort to meet an objective on his individualized education program that targets functional language and communication skills, Brian's teacher taught him to say, "Hello, how are you?" as a greeting. Now, whenever Brian meets anyone, he invariably responds with, "Hello, how are you?" Brian's parents are concerned that their son's language seems stilted and parrot-like.

The mere passage of time resulted in Sherry losing her ability to complete assignments. A change of scenery threw Ricardo off his game; the excellent work habits he acquired at the vocational training center were absent at the community job site. Although Brian used his new greeting skill over time and with new people, its repetitive and restricted form did not serve him well.

Each of these three situations illustrates a common type of teaching failure. The most socially significant behavior changes last over time, are used in all relevant settings and situations, and are accompanied by other functionally related responses. The student who learns to count money and make change in the classroom today must be able to count and make change at the convenience store tomorrow and at the supermarket next month. The beginning writer who has been taught to write a few good sentences in school must be able to write many more meaningful sentences when writing notes or letters to family or friends.

Applied behavior analysts face no more challenging or important task than that of designing, implementing, and evaluating interventions that produce generalized behavior change. This chapter defines three major types of generalized behavior change and describes the strategies and tactics researchers and practitioners use most often to promote them.

GENERALIZED BEHAVIOR CHANGE: DEFINITIONS AND KEY CONCEPTS

Baer, Wolf, and Risley (1968) included **generalized behavior change** as one of seven defining characteristics of applied behavior analysis.

> A behavior change may be said to have generality if it proves durable over time, if it appears in a wide variety of possible environments, or if it spreads to a wide variety of related behaviors. (p. 96)

In their seminal review paper, "An Implicit Technology of Generalization," Stokes and Baer (1977) also stressed those three facets of generalized behavior change—across time, settings, and behaviors—when they defined *generalization* as

> the occurrence of relevant behavior under different, nontraining conditions (i.e., across subjects, settings,

> people, behaviors, and/or time) without the scheduling of the same events in those conditions. Thus, generalization may be claimed when no extratraining manipulations are needed for extratraining changes; or may be claimed when some extra manipulations are necessary, but their cost is clearly less than that of the direct intervention. Generalization will not be claimed when similar events are necessary for similar effects across conditions. (p. 350)

In other words, when a learner emits a trained behavior in places or at times without having to be retrained completely in those places or times, or emits functionally related behaviors that were not taught directly, generalized behavior change is evident. The following sections define and provide examples of these three basic forms of generalized behavior change: response maintenance, setting/situation generalization, and response generalization.

Response Maintenance

We define **response maintenance** as the extent to which a learner continues to perform a target behavior after a portion or all of the intervention responsible for the behavior's initial appearance in the learner's repertoire has been terminated.[1] For example:

- Sayaka was having difficulty identifying the lowest common denominator (LCD) when adding and subtracting fractions. Her teacher had Sayaka write the steps for finding the LCD on an index card and told her to refer to the card when needed. Sayaka began using the LCD cue card, and the accuracy of her math assignments improved. After using the cue card for a week, Sayaka said she no longer needed it and returned it to her teacher. The next day Sayaka correctly computes the LCD for every problem on a quiz on adding and subtracting fractions.
- On Loraine's first day on the job with a residential landscaping company, a coworker taught her how to use a long-handled tool to extract dandelions. Without further instruction, Loraine continues to use the tool correctly a month later.
- When Derek was in the seventh grade, one of his teachers taught him to record his assignments and keep materials for each class in separate folders. Now a college sophomore, Derek continues to apply those organizational skills to his academic work.

Response maintenance was evident in Sayaka's performance on a math quiz 1 day after the cue card intervention ended, in Loraine's effective use of the weeding tool 1 month after training, and in Derek's continued use of the organizational skills he had learned years earlier. How long a newly learned behavior must be maintained depends on how long the learner's environment presents opportunities or requirements to perform the behavior. If covertly reciting a phone number 3 times immediately after hearing it enables a person without a cell phone to remember the number long enough to tap it in on a borrowed phone a few minutes later, sufficient response maintenance has been achieved. Other behaviors, such as literacy, self-care, and social skills, must be maintained in a person's repertoire for a lifetime.

Meaningful response maintenance may be obtained with some components of the initial intervention in place. A study by Sprague and Horner (1984), in which six students with moderate to severe cognitive disabilities were taught to use vending machines, provides a good example of this point. The students were given cue cards to aid them in operating vending machines without assistance. The cue cards had food and drink logos on one side and pictures of quarters paired with prices on the other. The cards were used during instruction and generalization probes, but also were kept by the students at the end of the program. Five of the six students still carried a cue card and used vending machines independently 18 months after the study had ended.

Setting/Situation Generalization

Setting/situation generalization is the extent to which a learner emits a target behavior in a setting or stimulus situation that differs from the instructional setting in any meaningful way. For example:

- While waiting for his new motorized wheelchair to arrive from the factory, Chaz used a computer simulation program and a joystick to learn how to operate his soon-to-arrive chair. When the new chair arrived, Chaz grabbed the joystick and immediately began zipping up and down the hall and spinning perfectly executed donuts.
- Loraine was taught to pull weeds from flowerbeds and mulched areas. Although never having been instructed to do so, Loraine began removing weeds from lawns she crossed on her way to the flowerbeds.
- After Brandy's teacher taught her to read 10 different C-V-C-E words (e.g., *bike, cute, made*), Brandy could read other C-V-C-E words for which she had not received instruction (e.g., *bite, cake, mute*).

A study by van den Pol and colleagues (1981) provides an excellent example of setting/situation generalization. They taught three young adults with multiple disabilities to eat independently in fast-food restaurants. All three students had previously eaten in restaurants, but could not order or pay for a meal without assistance. The researchers began by constructing a task analysis of the steps required to order, pay for, and eat a meal appropriately in a fast-food restaurant. Instruction took place in the students' classroom and consisted of role playing each of the steps during simulated customer–cashier interactions and responding to questions about photographic slides showing customers at a fast-food restaurant performing the various steps in the sequence. The 22 steps in the task analysis were divided into four major components: locating, ordering, paying, and eating and exiting. After a student had mastered the steps in each component in the classroom, he was given "a randomly determined number of bills equaling two to five dollars and instructed to go eat lunch" at a local restaurant (p. 64). Observers stationed inside the restaurant recorded each student's performance of each step in the task analysis. The results of these generalization probes, which

were also conducted before training (baseline) and after training (follow-up), are shown in Figure 30.1. In addition to assessing the degree of generalization from the classroom, which was based on the specific McDonald's restaurant used for most of the probes, the researchers conducted follow-up probes in a Burger King restaurant (also a measure of maintenance).

This study exemplifies the pragmatic approach used by most applied behavior analysts to assess and promote generalized behavior change. The setting in which generalized responding is desired can contain one or more components of the intervention that was implemented in the instructional environment, but not all of the components. If the complete intervention program is required to produce behavior change in a novel environment, then no setting/situation generalization can be claimed. However, if some component or components of the training program result in meaningful behavior change in a generalization setting, then setting/situation generalization can be claimed, provided it can be shown that the component or components used in the generalization setting were insufficient to produce the behavior change alone in the training environment.

For example, van den Pol and colleagues taught Student 3, who was deaf, how to use a prosthetic ordering device in the classroom. The device, a plastic laminated sheet of cardboard with a wax pencil, had preprinted questions (e.g., "How much is . . . ?"), generic item names (e.g., large hamburger), and spaces where the cashier could write responses. Simply giving the student some money and the prosthetic ordering card would not have enabled him to order, purchase, and eat a meal independently. However, after classroom instruction that included guided practice, role playing, social reinforcement ("Good job! You remembered to ask for your change" [p. 64]), corrective feedback, and review sessions with the prosthetic ordering card produced the desired behaviors in the instructional setting. Student 3 was able to order, pay for, and eat meals in a restaurant, aided only by the card.

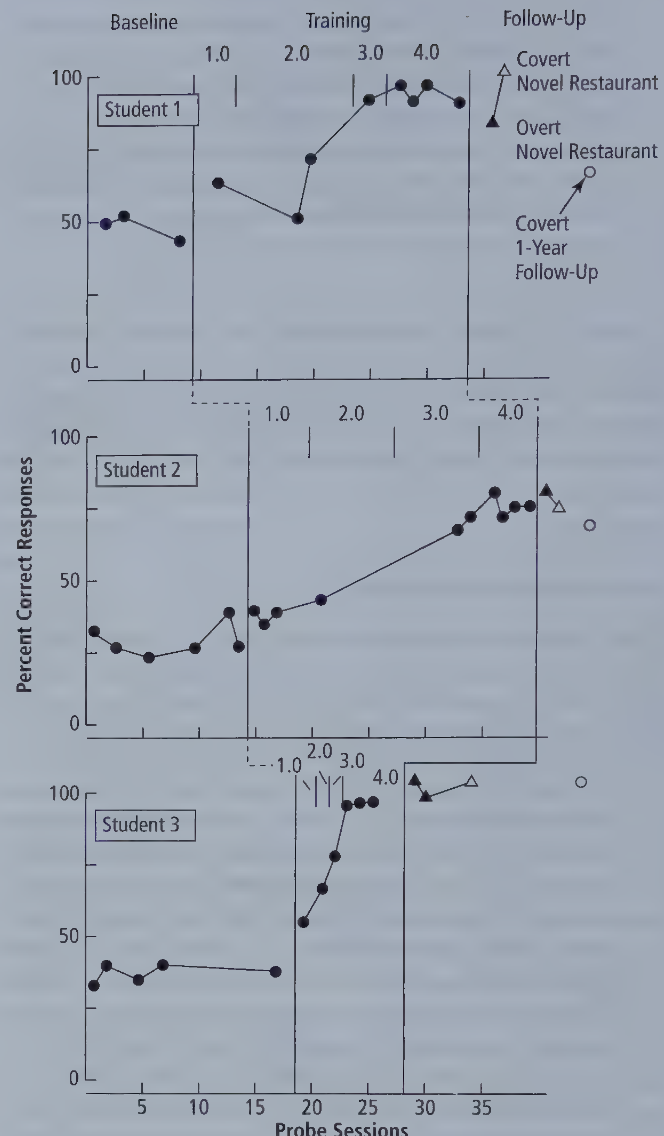

Figure 30.1 Percentage of steps necessary to order a meal at a fast-food restaurant correctly performed by three students with disabilities before, during, and after instruction in the classroom. During follow-up, the closed triangles represent probes conducted at a Burger King restaurant using typical observation procedures, open triangles represent Burger King probes during which students did not know they were being observed, and open circles represent covert probes conducted in a different McDonald's 1 year after training.

Neef, and F. P. Whitley, 1981, *Journal of Applied Behavior Analysis, 14,* p. 66. Reproduced with permission of John Wiley & Sons, Inc.

Distinguishing Between Instructional and Generalization Settings

Instructional setting denotes the environment where teaching occurs, including all planned or unplanned aspects of the environment that may influence the learner's acquisition and generalization of the target behavior.[2] Planned elements are the stimuli and events the teacher has programmed to achieve initial behavior change and promote generalization. For example, planned elements for a math lesson would include the specific problems and solution steps to be presented and the format and sequencing of those items. Unplanned aspects of the instructional setting are factors the teacher is not aware of or has not considered that might affect the acquisition and generalization of the target behavior. For example, the phrase *how much* in a word problem may acquire stimulus control over a student's use of addition, even when the correct solution to the problem requires a different arithmetic operation. Or, perhaps a student always uses subtraction for the first problem on each page of word problems because a subtraction problem has always been presented first during instruction.

A **generalization setting** is any place or stimulus situation that differs from the instructional setting in some meaningful way and in which performance of the target behavior is desired. There are multiple generalization settings for many target behaviors. The student who learns to solve addition and subtraction word problems in the classroom must be able to solve similar problems at home, at the store, and in the dugout with teammates.

Examples of instructional and generalization settings for six target behaviors are shown in Figure 30.2. When a person uses a skill in an environment physically removed from the setting where she learned it—as with behaviors 1 through 3 in Figure 30.2—it is easy to understand that event as an example of generalization across settings. However, many important generalized outcomes occur across more subtle differences between the instructional setting and generalization setting. A generalization setting does not have to be some*where* different from the physical location where instruction is provided. Students often receive instruction in the same place where they will need to maintain and generalize what they have learned. In other words, the instructional setting and generalization setting can, and often do, share the same physical location (as with behaviors 4 through 6 in Figure 30.2).

Distinguishing Between Setting/Situation Generalization and Response Maintenance

Because any measure of setting/situation generalization is conducted after some instruction has taken place, it might be argued that setting/situation generalization and response maintenance are the same, or are inseparable phenomena at least. Most measures of setting/situation generalization provide information on response maintenance, and vice versa. For example, the post-training generalization probes conducted by van den Pol and colleagues (1981) at the Burger King restaurant and at the second McDonald's provided data on setting/situation generalization (i.e., to novel restaurants) and on response maintenance of up to 1 year. However, a functional distinction exists between setting/situation generalization and response maintenance, with each outcome presenting a somewhat different set of challenges for programming and ensuring enduring behavior change. When a behavior change produced in the classroom or clinic is not observed in the generalization environment, a lack of setting/situation generalization is evident. When a behavior change produced in the classroom or clinic has occurred at least once in the generalization setting and then ceases to occur, a lack of response maintenance is evident.

An experiment by Koegel and Rincover (1977) illustrates the functional difference between setting/situation generalization and response maintenance. Participants were three young boys with autism; each was mute, echolalic, or displayed no appropriate contextual speech. One-to-one instructional sessions were conducted in a small room with the trainer and child seated across from each other at a table. Each child was taught to imitate a series of responses (e.g., the trainer said, "Touch your [nose, ear]" or "Do this" and [raised his arm, clapped his hands]). Each 40-min session consisted of blocks of 10 training trials in the instructional setting alternated with blocks of 10 trials conducted by an unfamiliar adult standing outside, surrounded by trees. All correct responses in the instructional setting were followed by candy and social praise. During generalization trials, the children received the same instructions and model prompts as in the classroom, but no reinforcement or other consequences were provided for correct responses.

Figure 30.3 shows the percentage of trials in which each child responded correctly in the instructional setting and in the generalization setting. All three children learned to respond to the imitative models in the instructional setting. At the end of the experiment, all three children showed 0% correct responding in the generalization setting, but for different reasons. Child 1 and Child 3 began emitting correct responses in the generalization setting as their performances improved in the instructional setting; however, their generalized responding was not maintained (most likely the result of the extinction condition in effect in the generalization setting). The imitative responding acquired by Child 2 in the instructional setting never generalized to the outside setting. Therefore, the 0% correct responding at the experiment's conclusion confirms a lack of response maintenance for Child 1 and Child 3, but for Child 2 it represents a failure of setting generalization.

Figure 30.2 Examples of a possible instructional setting and a generalization setting for various target behaviors.

Instructional Setting	Generalization Setting
1. Raising hand when *special education teacher* asks a question in the *resource room.*	1. Raising hand when *general education teacher* asks a question in the *regular classroom.*
2. Practicing conversational skills with *speech therapist at school.*	2. Talking with *peers in town.*
3. Passing basketball during a *team scrimmage on home court.*	3. Passing basketball during a *game on the opponent's court.*
4. Answering *addition problems in vertical format* at desk at school.	4. Answering *addition problems in horizontal format* at desk at school.
5. Solving *word problems with no distracter* numbers on homework assignment.	5. Solving *word problems* with *distracter numbers* on homework assignment.
6. Operating package sealer at community job site *in presence of supervisor.*	6. Operating package sealer at community job site *in absence of supervisor.*

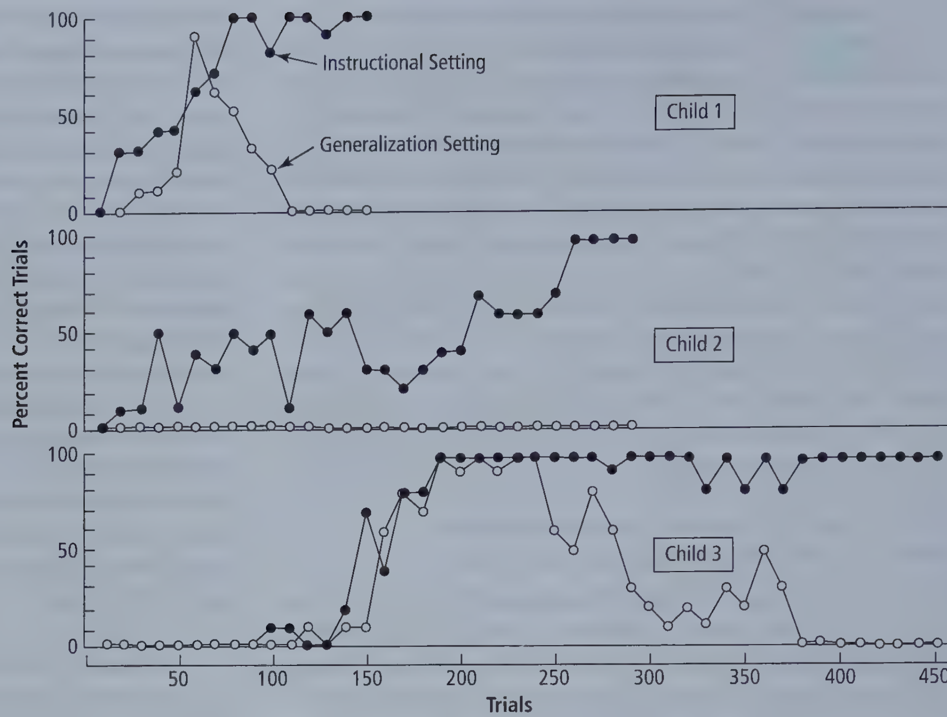

Figure 30.3 Correct responding by three children on alternating blocks of 10 trials in the instructional setting and 10 trials in the generalization setting.

From "Research on the Differences Between Generalization and Maintenance in Extra-Therapy Responding" by R. L. Koegel and A. Rincover, 1977, *Journal of Applied Behavior Analysis, 10,* p. 4. Reproduced with permission of John Wiley & Sons, Inc.

Response Generalization

Response generalization is the extent to which a learner emits untrained responses that are functionally equivalent to the trained target behavior. In other words, in response generalization useful variations of the target behavior appear for which no instructional contingencies have been applied. For example:

- Traci wanted to earn some extra money by helping her older brother with his lawn mowing business. Her brother taught Traci to walk the mower up and down parallel rows that progressed from one side of a lawn to the other. Traci discovered that she could mow some lawns just as quickly by first cutting around the perimeter and then walking the mower in a concentric pattern toward the center of the lawn.
- Loraine was taught to remove weeds with a long weed-removal tool. Although never taught or asked to do so, sometimes Loraine removes weeds with a hand trowel or with her bare hands.
- Michael's mother taught him how to take phone messages by using the pencil and notepaper next to the phone to write the caller's name, phone number, and message. One day, Michael's mother came home and saw her son's tape recorder next to the phone. She pushed the play button and heard Michael's voice say, "Grandma called. She wants to know what you'd like her to cook for dinner Wednesday. Mr. Stone called. His number is 555-1234. He said your car is ready to be picked up."

The study by Goetz and Baer (1973) described in Chapter 8 of three preschool girls' block building provides a good example of response generalization. During baseline, the teacher sat by each girl as she played with the blocks, watching closely but quietly, and displaying neither enthusiasm nor criticism for any particular use of the blocks. During the next condition, each time the child placed or rearranged the blocks to create a form that had not appeared previously in that session's constructions, the teacher commented with enthusiasm and interest (e.g., "Oh, that's very nice—that's different!"). Another condition followed in which each repeated construction of a form within the session was praised (e.g., "How nice—another arch!"). The study ended with a phase in which descriptive praise was again contingent on the construction of different block forms. All three children constructed more new forms with the blocks when form diversity was praised than under baseline or the praise-for-the-same-forms condition (see Figure 8.7).

Even though specific responses produced reinforcement (i.e., the actual block forms that preceded each instance of teacher praise), other responses sharing that functional characteristic (i.e., being different from block forms constructed previously by the child) increased in frequency as a function of the teacher's praise. As a result, during reinforcement for different forms, the children constructed new forms with the blocks even though each new form itself had never before appeared and therefore could not have been reinforced previously. Reinforcing a few members of the response class of new forms increased the frequency of other members of the same response class.

Generalized Behavior Change: A Relative and Intermingled Outcome

Generalized behavior change is a relative concept; it exists along a continuum. At one end of the continuum is a minimum amount of generalized behavior change—the learner uses the new skill in a limited range of nontraining settings and situations where contrived response prompts and/or consequences still might need to be applied. At the other end of the continuum lies maximum generalized behavior change; that is, after all components of an

intervention have been terminated, the learner emits the newly acquired target behavior and several functionally related behaviors not observed previously at every appropriate opportunity, in all relevant settings, and performs them indefinitely and independently.

We have presented the three primary types of generalized behavior change individually to isolate their defining features, but they often overlap and occur in combination. Although it is possible to obtain response maintenance without generalization across settings/situations or behaviors (i.e., the target behavior continues to occur in the same setting in which it was trained after the training contingencies have been terminated), all meaningful measures of setting generalization also entail some degree of response maintenance. And it is common for all three forms of generalized behavior change to be represented in the same instance. For example, during a relatively quiet shift at the widget factory on Monday, Joyce's supervisor taught her to obtain assistance by calling out, "Ms. Johnson, I need some help." Later that week (response maintenance) when it was very noisy on the factory floor (setting/situation generalization), Joyce signaled her supervisor by waving her hand back and forth (response generalization).

Generalized Behavior Change Is Not Always Desirable

It is hard to imagine any behavior important enough to target for systematic instruction for which response maintenance would be undesirable.[3] However, unwanted setting/situation generalization and response generalization occur often, and practitioners should design intervention plans to prevent or minimize such unwanted outcomes. Undesirable setting/situation generalization takes two common forms: overgeneralization and faulty stimulus control.

Overgeneralization, a nontechnical but effectively descriptive term, refers to an outcome in which the behavior has come under the control of an overly broad stimulus class. That is, the learner emits the target behavior in the presence of stimuli that, although similar in some way to the instructional examples or situation, are inappropriate occasions for the behavior. For example, a student learns to spell *division, mission*, and *fusion* with the grapheme *–sion*. When asked to spell *fraction*, the student writes *f-r-a-c-s-i-o-n*.

With *faulty stimulus control*, the target behavior comes under the restricted control of an irrelevant antecedent stimulus. For example, after learning to solve word problems such as "Ling has 3 books. Nikola has 5 books. How many books do they have in total?" by adding the numerals in the problem, the student adds the numerals in any problem containing "in total" (e.g., "Raluca has 3 candies. Corinne and Raluca have 8 candies in total. How many candies does Corrine have?").[4]

Undesired response generalization occurs when a learner's untrained but functionally equivalent responses result in poor performance or undesirable outcomes. For example, although Jack's supervisor at the widget factory taught him to operate the drill press with two hands because that is the safest method, sometimes Jack operates the press with one hand. One-handed and two-handed responses are functionally equivalent because both topographies produce widgets, but one-handed responses compromise Jack's health and the factory's safety record. Or, perhaps some of her brother's customers do not like how their lawns look after Traci has mowed them in concentric rectangles.

Box 30.1: "Perspectives on the Sometimes Confusing and Misleading Terminology of Generalization" discusses the varied terms applied behavior analysts use to describe these outcomes.

Other Types of Generalized Outcomes

Other types of generalized outcomes that do not fit easily into categories of response maintenance, setting/situation generalization, and response generalization have been reported in the behavior analysis literature. Complex components of a person's repertoire sometimes appear quickly with little or no apparent direct conditioning. A variety of such emergent performances are described as *stimulus equivalence* relations (Sidman, 1994, 2000), *recombinative generalization* (Axe & Sainato, 2010; Goldstein, 1983), *bidirectional naming* (Horne & Lowe, 1996; Miguel, 2016), and *relational frame theory* (Hayes, Barnes-Holmes, & Roche, 2001) (see chapters 18, 19, and 20). Another type of rapid learning that appears to be a generalized outcome of other events has been called *contingency adduction*, a process whereby behaviors initially established under one set of contingency conditions are recruited and recombined by a different set of contingencies and take on a new function in a person's repertoire (Andronis, Layng, & Goldiamond, 1997; Layng, Twyman, & Stikeleather 2004).

Sometimes an intervention applied to one or more people results in behavior changes in other people who were not directly treated by the contingencies. **Generalization across subjects** refers to changes in the behavior of people not directly treated by an intervention as a function of treatment contingencies applied to other people. This phenomenon, which has been described with a variety of related or synonymous terms—*vicarious reinforcement* (Bandura, 1971; Kazdin, 1973), *ripple effect* (Kounin, 1970), and *spillover effect* (Strain, Shores, & Kerr, 1976)—provides another dimension for assessing the generalization of treatment effects. For example, Fantuzzo and Clement (1981) examined the degree to which behavior changes would generalize from one child who received teacher-administered or self-administered token reinforcement during a math activity to a peer seated next to the child.

Drabman, Hammer, and Rosenbaum (1979) combined four basic types of generalized treatment effects—(a) across time (i.e., response maintenance), (b) across settings (i.e., setting/situation generalization), (c) across behaviors (i.e., response generalization), and (d) across subjects—into a conceptual framework they called the *generalization map*. By viewing each type of generalized outcome as dichotomous (i.e., either present or absent) and by combining all possible permutations of the four categories, Drabman and colleagues arrived at 16 categories of generalized behavior change ranging from maintenance (Class 1) to subject-behavior-setting-time generalization (Class 16). Class 1 generalization is evident if the target behavior of the target subject(s) continues in the treatment setting after any "experiment-controlled contingencies" have been discontinued. Class 16 generalization, the "ultimate form" of generalization, is evidenced by "a change in a nontarget subject's nontarget behavior which endures in a different setting after the contingencies have been withdrawn in the treatment setting" (p. 213).

BOX 30.1

Perspectives on the Sometimes Confusing and Misleading Terminology of Generalization

Applied behavior analysts use a variety of terms to describe behavior changes that appear as adjuncts or by-products of direct intervention. The overlapping and multiple meanings of these terms can lead to confusion and misunderstanding. For example, *maintenance*, the most frequently used term for a behavior change that persists after the intervention that brought it about has been withdrawn or terminated, is also the most common name for an experimental condition in which treatment has been discontinued or partially withdrawn. Applied behavior analysts should distinguish between *response maintenance* as a measure of behavior (i.e., a dependent variable) and *maintenance* as an experimental condition (i.e., an independent variable). Other terms found in the behavior analysis literature for continued responding after programmed contingencies have ended include *durability, behavioral persistence, resurgence*, and (often incorrectly) *resistance to extinction*.

Response maintenance can be measured under extinction conditions, in which case the relative frequency of continued responding is described correctly as *resistance to extinction* (see Chapter 24). However, using *resistance to extinction* to describe response maintenance in most applied situations is incorrect because reinforcement of some kind typically follows some occurrences of the target behavior in the post-treatment environment.

Terms used in the applied behavior analysis literature for behavior changes that occur in nontraining settings or stimulus conditions include *stimulus generalization, setting generalization, transfer of training*, or simply, *generalization*. It is technically incorrect to use *stimulus generalization* to refer to the generalized behavior change achieved by many applied interventions. *Stimulus generalization* is a technical term referring to a specific behavioral process: a response that has been reinforced in the presence of a given stimulus occurring more often in the presence of different but similar stimuli under extinction conditions (Guttman & Kalish, 1956; see Chapter 17). Use of the term should be restricted to that phenomenon.

The occurrence of behaviors that have not been trained directly may be referred to as *collateral* or *side effects, response variability, induction*, or *concomitant behavior change*. To further complicate matters, *generalization* is often used as a catchall term to refer to all three types of generalized behavior change.

Johnston (1979) discussed some problems caused by using *generalization* to describe any desirable behavior change in a generalization setting.

> This kind of usage is misleading in that it suggests that a single phenomenon is at work when actually a number of different phenomena need to be described, explained, and controlled. . . . Carefully designing procedures to optimize the contributions of stimulus and response generalization would hardly exhaust our repertoire of tactics for getting the subject to behave in a desirable way in non-instructional settings. Our successes will be more frequent when we realize that maximizing behavioral influence in such settings requires careful consideration of *all* behavioral principles and processes. (pp. 1–2)

Inconsistent use of the "terminology of generalization" can lead researchers and practitioners to incorrect assumptions and conclusions regarding the principles and processes responsible for the presence or absence of generalized outcomes. Nevertheless, applied behavior analysts will probably continue to use *generalization* as a dual-purpose term, referring sometimes to types of behavior change and sometimes to behavioral principles and processes that produce such changes. Stokes and Baer (1977) clearly indicated their awareness of the differences in definitions.

> The notion of generalization developed here is an essentially pragmatic one; it does not closely follow the traditional conceptualizations (Keller & Schoenfeld, 1950; Skinner, 1953). In many ways, this discussion will sidestep much of the controversy concerning terminology. (p. 350)

While discussing the use of naturally existing contingencies of reinforcement to maintain and extend programmed behavior changes, Baer (1999) explained his preference for using the term *generalization*:

> It is the best of the techniques described here and, interestingly, it does not deserve the textbook definition of "generalization." It is a reinforcement technique, and the textbook definition of generalization refers to unreinforced behavior changes resulting from other directly reinforced behavior changes. . . . [But] we are dealing with the pragmatic use of the word *generalization*, not the textbook meaning. We reinforce each other for using the word pragmatically, and it serves us well enough so far, so we shall probably maintain this imprecise usage. (p. 30, emphasis in original)

In an effort to promote the precise use of the technical terminology of behavior analysis and as a reminder that the phenomena of interest are usually products of multiple principles and procedures, we use terms that focus on the type of generalized behavior change rather than the variables that bring it about.

Although Drabman and colleagues recognized that "the classifications may prove arbitrary" (p. 204), they provided objectively stated rules for determining whether a given event fits the requirements of each of their 16 classifications. Regardless of whether generalized behavior change consists of such distinctly separate and wide-ranging phenomena as detailed by Drabman and colleagues, their generalization map provided an objective framework with which researchers can assess the extended effects of behavioral interventions (Allen, Tarnowski, Simonian, Elliot, & Drabman, 1991). For example, Stevenson and Fantuzzo (1984) measured 15 of the 16 generalization map categories in a study of the effects of teaching a fifth-grade boy to use self-management techniques. They not only measured the effects of the intervention on the target behavior (math performance) in the instructional setting (school), but also assessed effects on the student's math behavior at home, disruptive behavior at home and at school, both behaviors for a nontreated peer in both settings, and maintenance of all of the above.

PLANNING FOR GENERALIZED BEHAVIOR CHANGE

> *In general, generalization should be programmed, rather than expected or lamented.*
>
> —Baer, Wolf, and Risley (1968, p. 97)

In their review of 270 published studies relevant to generalized behavior change, Stokes and Baer (1977) concluded that practitioners should always "assume that generalization does not occur except through some form of programming . . . and act as if there were no such animal as 'free' generalization—as if generalization never occurs 'naturally,' but always requires programming" (p. 365). Of course, generalization of some type and degree usually occurs, whether or not it is planned. Unplanned and unprogrammed generalization may be sufficient, but often it is not, particularly for many learners served by applied behavior analysts (e.g., children and adults with learning problems and developmental disabilities). And if left unchecked, unplanned generalized outcomes may be undesirable outcomes.

Achieving optimal generalized outcomes requires thoughtful, systematic planning. This planning begins with two major steps: (1) selecting target behaviors that will meet natural contingencies of reinforcement and (2) specifying all desired variations of the target behavior and the settings/situations in which those behaviors should (and should not) occur after instruction has ended.

Select Target Behaviors that will Meet Naturally Existing Contingencies of Reinforcement

> *The everyday environment is full of steady, dependable, hardworking sources of reinforcement for almost all of the behaviors that seem natural to us. That is why they seem natural.*
>
> —Donald M. Baer (1999, p. 15)

Numerous criteria have been suggested for determining whether a proposed teaching objective is relevant or functional for the learner. Age appropriateness and the degree to which a skill represents normalization are often cited as important criteria when selecting target behaviors for students with disabilities (e.g., Brown, McDonnell, & Snell, 2016). These criteria were discussed in Chapter 3, along with numerous other issues that should be considered when selecting and prioritizing target behaviors. In the end, however, there is just one ultimate criterion of functionality: *A behavior is functional only to the extent that it produces reinforcement for the learner.* This criterion holds no matter how important the behavior may be to the person's health or welfare, or no matter how much teachers, family, friends, or the learner herself considers the behavior to be desirable. We repeat: A behavior is not functional if it does not produce reinforcement for the learner. We can say this another way: Behaviors that are not followed by reinforcers on at least some occasions will not be maintained.

Ayllon and Azrin (1968) recognized this fundamental truth when they recommended that when selecting target behaviors practitioners follow the *relevance-of-behavior rule*: Choose only those behaviors to change that will produce reinforcers in the learner's postintervention environment. Baer (1999) believed so strongly in the importance of this criterion that he recommended practitioners heed a similar rule:

> *A good rule is to not make any deliberate behavior changes that will not meet natural communities of reinforcement.* Breaking this rule commits you to maintain and extend the behavior changes that you want, by yourself, indefinitely. If you break this rule, do so knowingly. Be sure that you are willing and able to do what will be necessary. (p. 16, emphasis in original)

Promoting for the generalization and maintenance of any behavior change for which a natural contingency of reinforcement exists, no matter the specific tactics employed, consists of getting the learner to emit the behavior in the generalization setting just often enough to contact the contingency. Generalization and maintenance of the behavior from that point forward, while not ensured, is a very good bet. For example, after receiving some basic instruction on how to operate the steering wheel, gas pedal, and brakes on a car, the naturally existing reinforcement and punishment contingencies involving moving automobiles and the road will select and maintain effective steering, acceleration, and braking. Few drivers need booster training sessions on the basic operation of the steering wheel, gas pedal, and brakes.

We define a **naturally existing contingency** as any contingency of reinforcement (or punishment) that operates independent of the behavior analyst's or practitioner's efforts. Naturally existing contingencies include those that operate without social mediation (e.g., walking fast on an icy sidewalk is often punished by a slip and fall) and socially mediated contingencies contrived and implemented by other people in the generalization setting. From the perspective of a special educator who is teaching a set of targeted social and academic skills to students for whom the general education classroom represents the generalization setting, a token economy operated by the general education classroom teacher is an example of the latter type of naturally existing contingency. Although the general education teacher contrived the token economy, it represents a set of naturally existing contingencies because it already operates in the generalization setting.

We define a **contrived contingency** as any contingency of reinforcement (or punishment) designed and implemented by a behavior analyst or practitioner to achieve the acquisition, maintenance, and/or generalization of a targeted behavior change. The token economy in the previous example is a contrived contingency from the perspective of the general education teacher who designed and implemented it.

Practitioners are often charged with the difficult task of teaching important skills for which there are no dependable naturally existing contingencies of reinforcement. In such cases, practitioners should realize and plan for the fact that the generalization and maintenance of target behaviors will have to be supported, perhaps indefinitely, with contrived contingencies.

Specify All Desired Variations of the Behavior and the Settings/Situations Where Those Behaviors Should (and Should Not) Occur

This stage of planning for generalized outcomes includes identifying all the desired behavior changes that need to be made and all the environments and stimulus conditions in which the learner should emit the target behavior(s) after direct training has ceased (Baer, 1999). For some target behaviors, the most important stimulus control for each response variation is clearly defined (e.g., reading C-V-C-E words) and restricted in number (e.g., solving single-digit multiplication facts). For many important target behaviors, however, the learner is likely to encounter a multitude of settings and stimulus conditions in which the behavior, in a variety of response forms, is desired. Only by considering these possibilities prior to instruction can the behavior analyst design an intervention with the best chance of preparing the learner for them.

In one sense, this component of planning for generalized outcomes is similar to preparing a student for a future test without knowing the content or format of all the questions that will be on the test. The stimulus conditions and contingencies of reinforcement in the generalization setting(s) will provide that test to the learner. Planning involves trying to determine what the final exam will cover (type and form of questions), whether any trick questions will appear (e.g., confusing stimuli that might evoke the target response when it should not occur), and whether the learner will need to use his new knowledge or skill in different ways (response generalization).

List All the Behaviors that Need to be Changed

Listing all behaviors that require change is not an easy task, but a necessary one to obtain a complete picture of the teaching task ahead. For example, if the target behavior is teaching Brian, the young boy with autism, to greet people, he should learn a variety of greetings in addition to "Hello, how are you?" Brian may also need to learn behaviors to initiate and participate in conversations, such as responding to questions, taking turns, staying on topic, and so forth. Further, he may need to be taught when and to whom he should introduce himself. Only by having a complete list of all the desired forms of the behavior can the practitioner make meaningful decisions about which behaviors to teach directly and which to leave to generalization.

The practitioner should determine whether and to what extent response generalization is desirable for all of the behavior changes listed, and then make a prioritized list of the variations of the target behavior she would like to see as generalized outcomes.

List All the Settings and Situations in Which the Target Behavior Should Occur

A list should be made of all the desired settings and situations in which the learner will emit the target behavior if optimal generalization is achieved. Will Brian need to introduce himself and talk with children his own age, to adults, to males and females? Will he need to talk with others at home, at school, in the lunchroom, on the playground? Will he be confronted with situations that may appear to be appropriate opportunities to converse but are not (e.g., an unknown adult approaches and offers candy) and for which an alternative response is needed (e.g., walking away, seeking out a known adult). (This kind of analysis often adds extra behaviors to the list of skills to be taught.)

When all of the possible situations and settings have been identified, they should be prioritized according to their importance and the client's likelihood of encountering them. Further analysis of the prioritized environments should then be conducted. What discriminative stimuli usually set the occasion for the target behavior in these various settings and situations? What schedules of reinforcement for the target behavior are typical in these nontraining environments? What kinds of reinforcers are likely to be contingent on the emission of the target behavior in each of the settings? Only when the behavior analyst has answered all of these questions, if not by objective observation, then at least by considered estimation, can she begin to have a full picture of the teaching task ahead.

Is All This Preintervention Planning Worth It?

Obtaining the information just described requires considerable time and effort. Given limited resources, why not design an intervention and immediately begin trying to change the target behavior? It is true that many behavior changes do show generalization, even though the extension of the trained behavior across time, settings, and other behaviors was unplanned and unprogrammed. When target behaviors have been chosen that are truly functional for the subject, and when those behaviors have been brought to a high level of proficiency under discriminative stimuli relevant to generalization settings, the chances of generalization are good. But what constitutes a high level of proficiency for certain behaviors in various settings? What are all of the relevant discriminative stimuli in all of the relevant settings? What are all the relevant settings?

Without a systematic plan, a practitioner will usually be ignorant of the answers to these vital questions. Few behaviors important enough to target have such limited needs for generalized outcomes that the answers to such questions are obvious. Just a cursory consideration of the behaviors, settings, and people related to a child introducing himself revealed numerous factors that may need to be incorporated into an instructional plan. A more thorough analysis would produce many more. In

fact, a complete analysis will invariably reveal more behaviors to be taught than time or resources would ever allow. And Brian—the 10-year-old who is learning to greet people and introduce himself—in all likelihood needs to learn many other skills also, such as self-help, academic, and recreation and leisure skills, to name just a few. Why, then, create all the lists in the first place when everything cannot be taught anyway? Why not just train and hope?[5]

Baer (1999) described six possible benefits of listing all the forms of behavior change and all the situations in which these behavior changes should occur.

1. You now see the full scope of the problem ahead of you, and thus see the corresponding scope that your teaching program needs to have.
2. If you teach less than the full scope of the problem, you do so by choice rather than by forgetting that some forms of the behavior could be important, or that there were some other situations in which the behavior change should or should not occur.
3. If less than a complete teaching program results in less than a complete set of behavior changes, you will not be surprised.
4. You can decide to teach less than there is to learn, perhaps because that is all that is practical or possible for you to do.
5. You can decide what is most important to teach. You can also decide to teach the behavior in a way that encourages the indirect development of some of the other forms of the desired behavior, as well as the indirect occurrence of the behavior in some other desired situations, that you will not or cannot teach directly.
6. But if you choose the option discussed in number 5 above, rather than the complete program implicit in number 1, you will do so knowing that the desired outcome would have been more certain had you taught every desirable behavior change directly. The best that you can do is to encourage the behavior changes that you do not cause directly. So, you will have chosen the option in number 5 either of necessity or else as a well-considered gamble after a thoughtful consideration of possibilities, costs, and benefits. (pp. 10–11)

After determining which behaviors to teach directly and in which situations and settings to teach those behaviors, the behavior analyst is ready to consider strategies and tactics for promoting generalized outcomes.

STRATEGIES AND TACTICS FOR PROMOTING GENERALIZED BEHAVIOR CHANGE

Various conceptual systems and methodological taxonomies for promoting generalized behavior change have been proposed (e.g., Horner, Dunlap, & Koegel, 1988; Osnes & Lieblein, 2003; Stokes & Baer, 1977; Stokes & Osnes, 1989). The conceptual scheme presented here is informed by the work of those authors and others, and by our experiences designing, implementing, and evaluating methods for promoting generalized outcomes and in teaching practitioners to use them. Although numerous methods and techniques have been demonstrated and given a variety of names, most tactics that effectively promote generalized behavior change can be classified under five strategic approaches:

- Teach the full range of relevant stimulus conditions and response requirements.
- Make the instructional setting similar to the generalization setting.
- Maximize the target behavior's contact with reinforcement in the generalization setting.
- Mediate generalization.
- Train to generalize.

In the following sections we describe and provide examples of 13 tactics used by applied behavior analysts to accomplish these five strategies (see Figure 30.4). Although each tactic is described individually, most interventions to promote generalized behavior change combine these tactics (e.g., Bord, Sidener, Reeve, & Disener, 2017; Grossi, Kimball, & Heward, 1994; Hughes, Harmer, Killina, & Niarhos, 1995; Trask-Tyler, Grossi, & Heward, 1994).

Teach the Full Range of Relevant Stimulus Conditions and Response Requirements

> *The most common mistake that teachers make, when they want to establish a generalized behavior change, is to teach one good example of it and expect the student to generalize from that example.*
>
> —Donald M. Baer (1999, p. 18)

Most important behaviors must be performed in various ways across a wide range of stimulus conditions. Consider a person skilled in reading, math, conversing with others, and cooking. That person can read thousands of different words; add, subtract, multiply, and divide any combination of numbers; make a multitude of relevant and appropriate comments when talking with others; and measure, combine, and prepare numerous ingredients in hundreds of recipes. Helping learners achieve such wide-ranging performances presents an enormous challenge to the practitioner.

One approach to this challenge would be to teach every desired form of a target behavior in every setting/situation in which the learner may need that behavior in the future. Although this approach would eliminate the need to program for response generalization and setting/situation generalization (response maintenance would remain an issue), pursuing it is seldom possible and never practical. A teacher cannot provide direct instruction on every printed word a student may encounter, or teach a student every measuring, pouring, stirring, and sautéing movement needed to prepare every dish he may want to make later on. Even for skill areas for which it would be *possible* to teach every possible example—instruction *could* be provided on all 900 single-digit-times-two-digit multiplication problems—to do so would be impractical for many reasons, not the least of which is that the student needs to learn not only many other types of math problems but also skills in other curriculum areas.

Figure 30.4 Strategies and tactics for promoting generalized behavior change.

Teach the Full-Range of Relevant Stimulus Conditions and Response Requirements
1. Teach enough stimulus examples.
2. Teach enough response examples.

Make the Instructional Setting Similar to the Generalization Setting
3. Program common stimuli.
4. Teach loosely.

Maximize Contact with Reinforcement in the Generalization Setting
5. Teach the target behavior to levels of performance required by naturally existing contingencies of reinforcement.
6. Program indiscriminable contingencies.
7. Set behavior traps.
8. Ask people in the generalization setting to reinforce the target behavior.
9. Teach the learner to recruit reinforcement.

Mediate Generalization
10. Contrive a mediating stimulus.
11. Teach self-management skills.

Train to Generalize
12. Reinforce response variability.
13. Instruct the learner to generalize.

A strategy called **teach enough examples** consists of teaching the student to respond to a subset of all of the possible stimulus and response examples and then probing the student's performance on untrained examples.[6] For example, the generalization of a student's ability to solve two-digit-minus-two-digit arithmetic problems with regrouping can be assessed by asking the student to solve several problems of the same type for which no instruction or guided practice has been provided. If the results of this **generalization probe** show that the student responds correctly to untaught examples, then instruction can be halted on this class of problems. If the student performs poorly on the generalization probe, the practitioner teaches additional examples before again assessing the student's performance on a new set of untaught examples. This cycle of teaching new examples and probing with untaught examples continues until the learner consistently responds correctly to untrained examples representing the full range of stimulus conditions and response requirements found in the generalization setting.

Teach Enough Stimulus Examples

The tactic for promoting setting/situation generalization called *teach enough stimulus examples* involves teaching the learner to respond correctly to multiple examples of antecedent stimulus conditions and probing for generalization to untaught stimulus examples. A different stimulus example is incorporated into the teaching program each time a change is made in any dimension of the instructional item itself or the environmental context in which the item is taught. Examples of four dimensions by which different instructional examples can be identified and programmed are the following:

- The specific *item* taught (e.g., multiplication facts: 7×2, 4×5; letter sounds: *a, t*)
- The *stimulus context* in which the item is taught (e.g., multiplication facts presented in vertical format, in horizontal format, in word problems; saying the sound of *t* when it appears at the beginning and end of words: *t*ab, ba*t*)
- The *setting* where instruction occurs (e.g., large-group instruction at school, collaborative learning group, home)
- The *person* doing the teaching (e.g., classroom teacher, peer, parent)

As a general rule, the more examples used during instruction, the more likely the learner will respond correctly to untrained examples or situations. The number of examples that must be taught before sufficient generalization occurs will vary as a function of factors such as the complexity of the target behavior being taught, the teaching procedures employed, the student's opportunities to emit the target behavior under the various conditions, the naturally existing contingencies of reinforcement, and the learner's history of reinforcement for generalized responding.

Sometimes teaching as few as two examples will produce significant generalization to untaught examples. Stokes, Baer, and Jackson (1974) taught a greeting response to four children with severe cognitive disabilities who seldom acknowledged or greeted other people. The senior author, working as a dormitory assistant, used unconditioned reinforcers (potato chips and M&M'S) and praise to shape the greeting response (at least two back-and-forth waves of a raised hand). Then this initial trainer maintained the newly learned hand wave by contriving three to six contacts per day with each of the children in various settings (e.g., playroom, corridor, dormitory, courtyard). Throughout the study, as many as 23 different staff members systematically approached the children during different times of the day in different settings and recorded whether the children greeted them with a hand waving response. If a child greeted a prober with the waving response, the prober responded with "Hello, (name)." Approximately 20 such generalization probes were conducted each day with each child.

Immediately after learning the greeting response with just one trainer, one of the children (Kerry) showed good

setting/situation generalization by using it appropriately in most of her contacts with other staff members. However, the other three children failed to greet staff members most of the time, even though they continued to greet the original trainer on virtually every occasion. A second staff member then began to reinforce and maintain the greeting responses of these three children. As a result of adding the second trainer, the children's greeting behavior showed widespread generalization to the other staff members. Stokes and colleagues' (1974) study is important for at least two reasons. First, it demonstrated an effective method for continual assessment of setting/situation generalization across numerous examples (in this case, people). Second, the study showed that widespread generalization may result from teaching just two examples.

Teach Enough Response Examples

Instruction that provides practice with a variety of response topographies helps ensure the acquisition of desired response forms and promotes response generalization in the form of untrained topographies. Often called **multiple-exemplar training**, this tactic typically incorporates both stimulus and response variations.[7] Multiple-exemplar training has promoted the generalization of a wide range of behaviors by diverse learners: auditory-visual discrimination tasks (Carr, 2003), empathy skills (Sivaraman, 2017), and sharing (Marzullo-Kerth, Reeve, Reeve, & Townsend, 2011) by children with autism; food preparation (Trask-Tyler, Grossi, & Heward, 1994), domestic skills (Neef, Lensbower, Hockersmith, DePalma, & Gray, 1990), vocational skills (Horner, Eberhard, & Sheehan, 1986), and requests for assistance (Chadsey-Rusch, Drasgow, Reinoehl, Halle, & Collet-Klingenberg, 1993) by children and young adults with disabilities; and identifying definitions of behavior analysis terms by university students (Meindl, Ivy, Miller, Neef, & Williamson, 2013).[8]

Four female high school students with moderate cognitive disabilities participated in a study by Hughes and colleagues (1995) that assessed the effects of an intervention they called *multiple-exemplar self-instructional training* on the acquisition and generalization of the students' conversational interactions with peers. The students were recommended for the study because they initiated conversations and responded to peers' efforts to talk with them at "low or nonexistent rates" and seldom maintained eye contact. One of the students, Tanya, had recently been refused a job at a restaurant because of her "reticence and lack of eye contact during her job interview" (p. 202).

A key element of Hughes and colleagues' intervention was practicing a wide variety of conversation starters and statements with different peer teachers. Ten volunteer peer teachers recruited from general education classrooms helped teach conversation skills to the participants. The peer teachers were male and female, ranged in grade level from freshmen to seniors, and represented African American, Asian American, and Euro-American ethnic groups. Instead of learning a few scripted conversation openers, the participants practiced using multiple examples of conversation starters selected from a pooled list of conversation openers used by general education students. Additionally, participants were encouraged to develop individual adaptations of statements, which further promoted response generalization by increasing the number and range of conversational statements that were likely to be used in subsequent conversations.

Before, during, and after multiple-exemplar training, generalization probes were conducted of each participant's use of self-instructions, eye contact, and initiating and responding to conversation partners. The 23 to 32 different students who served as conversation partners for each participant represented the full range of student characteristics in the school population (e.g., gender, age, ethnicity, students with and without disabilities) and included students who were known and unknown to the participants prior to the study. The rate of conversation initiations by all four participants increased during multiple-exemplar training to levels approximating those of general education students and was maintained at those rates after the intervention was terminated completely (see Figure 30.5).

General Case Analysis

Teaching a learner to respond correctly to multiple examples does not guarantee generalized responding to untaught examples. To achieve optimal generalization and discrimination, the behavior analyst must pay close attention to the specific examples used during instruction; not just any examples will do. Maximally effective instructional design requires selecting teaching examples that represent the full range of stimulus situations and response requirements in the natural environment.[9] **General case analysis** (also called *general case strategy*) is a systematic method for selecting teaching examples that represent the full range of stimulus variations and response requirements in the generalization setting (Albin & Horner, 1988; Becker & Engelmann, 1978).

A series of studies by Horner and colleagues demonstrated the importance of teaching examples that systematically sample the range of stimulus variations and response requirements the learner will encounter in the generalization setting (e.g., Horner et al., 1986; Horner & McDonald, 1982; Horner, Williams, & Steveley, 1987). In a classic example of this line of research, Sprague and Horner (1984) evaluated the effects of general case instruction on the generalized use of vending machines by six high school students with moderate to severe cognitive disabilities. The dependent variable was the number of vending machines each student operated correctly during generalization probes of 10 different machines located within the community. For a probe trial to be scored as correct, a student had to perform correctly a chain of five responses (i.e., insert the proper number of coins, activate the machine for the desired item, and so on). The researchers selected the 10 vending machines used to assess generalization because each student's performance on those machines would serve as an index of his performance "across all vending machines dispensing food and beverage items costing between $.20 and $.75 in Eugene, Oregon" (p. 274). None of the vending machines used in the generalization probes was identical to any of the vending machines used during instruction.

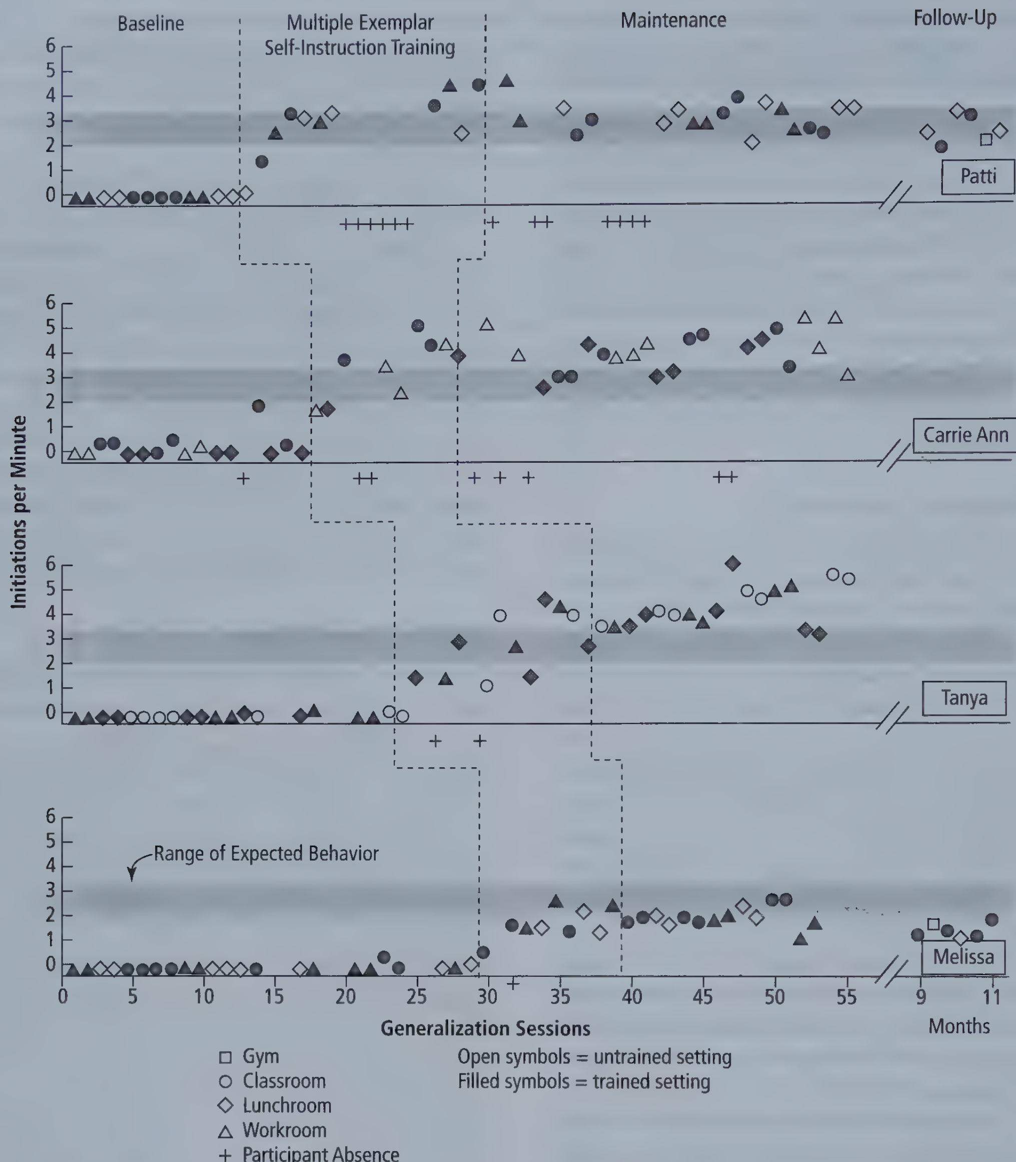

Figure 30.5 Conversation initiations per minute by four high school students with disabilities to conversation partners with and without disabilities during generalization sessions. The shaded bands represent typical performance by general education students.

From "The Effects of Multiple-Exemplar Training on High-School Students' Generalized Conversational Interactions" by C. Hughes, M. L. Harmer, D. J. Killina, and F. Niarhos, 1995. *Journal of Applied Behavior Analysis, 28,* p. 210. Reproduced with permission of John Wiley & Sons, Inc.

After a single-baseline probe verified each student's inability to use the 10 vending machines in the community, a condition the researchers called "single-instance instruction" began. Under this condition, each student received individual training on a single vending machine located in the school until he used the machine independently for three consecutive correct trials on each of 2 consecutive days. Even though each student had learned to operate the training machine without errors, the generalization probe following single-instance instruction revealed little or no success with the vending machines in the community (see Probe Session 2 in Figure 30.6). The continued poor performance by Students 2, 3, 5, and 6 on generalization probes that followed additional instruction with the single-instance training machine shows that "overlearning" on a single example does not necessarily aid generalization. Further evidence of the limited generalization obtained from single-instance instruction is the fact that seven of the eight total probe trials performed correctly by all students after single-instance instruction were on Probe Machine 1, the vending machine that most closely resembled the machine on which the students had been trained.

Next, multiple-instance training was implemented with Students 4, 5, and 6. The teaching procedures and performance criteria for multiple-instance training were the same as those used in the single-instance condition, except that each student received instruction until he reached criterion on three new machines. Sprague and Horner (1984) purposely selected vending machines to use in the multiple-instance instruction that

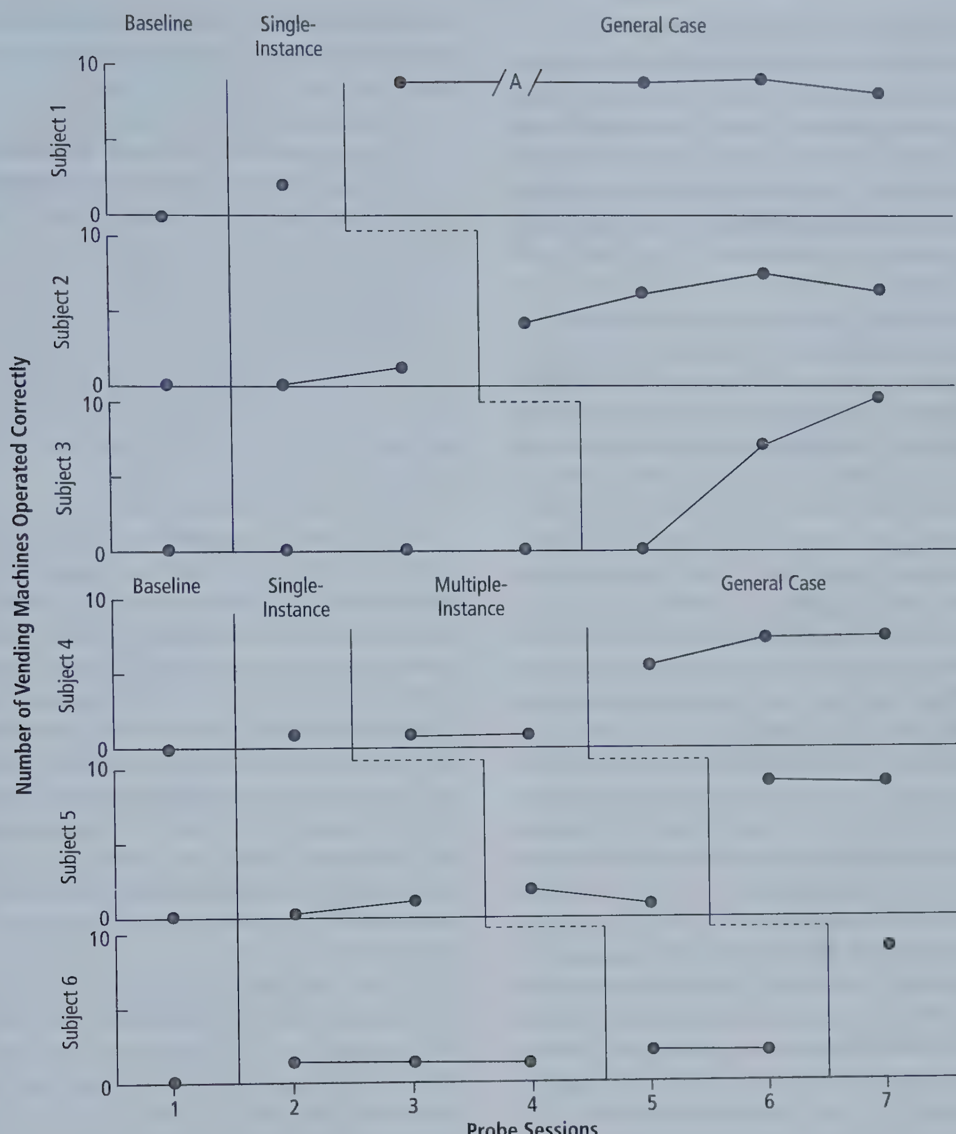

Figure 30.6 Number of nontrained vending machines operated correctly by students across phases and probe sessions.

From "The Effects of Single Instance, Multiple Instance, and General Case Training on Generalized Vending Machine Use by Moderately and Severely Handicapped Students," by J. R. Sprague and R. H. Horner, 1984, *Journal of Applied Behavior Analysis, 17,* p. 276. Reproduced with permission of John Wiley & Sons, Inc.

were similar to one another and that did not sample the range of stimulus variations and response requirements that defined the vending machines in the community. After reaching training criterion on three additional machines, Students 4, 5, and 6 were still unable to operate the machines in the community. During the six probe sessions that followed multiple-instance instruction, these students correctly completed only 9 of the 60 total trials.

The researchers then introduced general case instruction in multiple-baseline fashion across students. This condition was the same as multiple-instance instruction, except that the three different vending machines used in general case training, when combined with the single-instance machine, provided the students with practice across the total range of stimulus conditions and response variations found in vending machines in the community. None of the training machines, however, was exactly the same as any machine used in the generalization probes. After reaching training criterion on the general case machines, all six students showed substantial improvements in their performance on the 10 untrained machines. Sprague and Horner (1984) speculated that Student 3's poor performance on the first generalization probe following general case instruction was caused by a ritualistic pattern of inserting coins that he had developed during previous probe sessions. After receiving repeated practice on the coin insertion step during a training session between Probe Sessions 5 and 6, Student 3's performance on the generalization machines improved greatly.

Negative, or "Don't Do It," Teaching Examples

Teaching a student where and when to use a new skill or bit of knowledge does not mean that he also knows where and when *not* to use this newly learned behavior. Brian, for example, needs to learn that he should not say, "Hello, how are you?" to people that he has greeted within the past hour or so. Learners must be taught to discriminate the stimulus conditions that signal when responding is appropriate from stimulus conditions that signal when responding is inappropriate.

Instruction that includes "don't do it" teaching examples intermixed with positive examples provides learners with practice discriminating stimulus situations in which the target behavior should not be emitted (i.e., S^{Δ}s) from those conditions when the behavior is appropriate.[10] This sharpens the stimulus control necessary to master many concepts and skills (Engelmann & Carnine, 1982).

Horner and colleagues (1986) incorporated "don't do it" examples into a training program to teach four high school students with moderate to severe cognitive disabilities how to bus tables in cafeteria-style restaurants. To correctly bus a table, the student had to remove all dishes, silverware, and garbage from tabletop, chairs, and the floor under and around the table; wipe the tabletop; straighten chairs; and place dirty dishes and garbage in appropriate receptacles. In addition, the students were taught to inquire, through the use of cards, if a customer was finished with empty dishes. The three settings, one for training and two for generalization probes, differed in terms of size and furniture characteristics and configurations.

Each training trial required the student to attend to the following stimulus features of a table: (a) the presence or absence of people at a table, (b) whether people were eating at the table, (c) the amount and/or status of food on dishes, (d) the presence or absence of garbage at a table, and (e) the location of garbage and/or dirty dishes at a table. Training consisted of 30-min sessions involving six table types that represented the range of conditions most likely to be encountered in a cafeteria-style restaurant. A trainer modeled correct table busing and verbally prompted correct responding. When errors occurred, the trainer stopped the student, re-created the situation, and provided additional modeling and assistance. The six training examples consisted of four to-be-bused tables and two not-to-be-bused tables (see Table 30.1).

Generalization probe sessions were conducted in two restaurants not used for training. Each student was presented with 15 probe tables: 10 to-be-bused tables and 5 not-to-be-bused tables. The results showed a functional relation between general case instruction that included not-to-be-bused tables and "immediate and pronounced improvement in the percentage of probe tables responded to correctly" (p. 467).

Negative teaching examples are necessary when the learner must discriminate between appropriate and inappropriate conditions for a particular response. Practitioners should ask this question: Is responding *always appropriate* in the generalization setting(s)? If the answer is no, then "don't do it" teaching examples should be part of instruction.

Does the instructional setting naturally or automatically include a sufficient number and range of negative examples? The teaching situation must be analyzed to answer this important question. Practitioners may need to contrive some negative teaching examples. Practitioners should not assume the natural environment will readily reveal sufficient negative examples. Conducting training in the natural environment is no guarantee that learners will be exposed to stimulus situations that they are likely to encounter in the generalization environment after training. For example, in the study on teaching table busing, Horner and colleagues (1986) noted that, "on some days the trainer needed actively to set up one or more table types to ensure that a student had access to a table type that was not 'naturally' available" (p. 464).

"Don't do it" teaching examples should be selected and sequenced according to the degree to which they differ from positive examples (i.e., S^Ds). The most effective negative teaching examples will share many of the relevant characteristics of the positive teaching examples (Horner et al., 1988). For example, the "don't bus" tables used by Horner and colleagues (1986) shared many features with the "bus" tables (see Table 30.1). Such *minimum difference negative teaching examples* help the learner to perform the target behavior with the precision required

TABLE 30.1 Six Training Examples Used to Teach Students with Disabilities How to Bus Tables in Cafeteria-style Restaurants

Training Examples	Presence of People and Possessions	People Eating or Not Eating	Dishes: Empty/ Part/New Food	Garbage: Present or Not Present	Location of Garbage and Dishes	Correct Response
1	0 People + possessions	N/A	Partial	Present	Table, Chairs	Don't Bus
2	0 People	N/A	Partial	Present	Table, Floor, Chair	Bus
3	2 People	Eating	New food	Present	Table, Chair, Floor	Don't Bus
4	0 People	N/A	Empty	Present	Table, Floor	Bus
5	1 Person	Not eating	Empty	Present	Chair, Floor	Bus
6	2 People	Not eating	Empty	Present	Table	Bus

From "Teaching Generalized Table Bussing: The Importance of Negative Teaching Examples," by R. H. Horner, J. M. Eberhard, and M. R. Sheehan, 1986, *Behavior Modification, 10*, p. 465. Copyright 1986 by the Sage Publications, Inc. Used by permission.

by the natural environment. Minimum difference teaching examples help eliminate "generalization errors" due to overgeneralization and faulty stimulus control.

Make the Instructional Setting Similar to the Generalization Setting

> *Fresno State coach Pat Hill expects Ohio Stadium to be a new experience for the Bulldogs, who will visit for the first time. For a practice last week in FSU's stadium, Hill hired a production company to blast the Ohio State fight song—at about 90 decibels—throughout the two-hour session. "We created some noise and atmosphere to give us a feel of a live game," Hill said.*
>
> —Columbus Dispatch (August 27, 2000)[11]

A basic strategy for promoting generalization is to incorporate into the instructional setting stimuli the learner is likely to encounter in the generalization setting. The greater the similarity between the instructional environment and the generalization environment, the more likely the target behavior will be emitted in the generalization setting. The principle of stimulus generalization states that a behavior is likely to be emitted in the presence of stimuli that are very similar to the stimulus conditions in which the behavior was reinforced previously, but the behavior will likely not be emitted under stimulus conditions that differ significantly from the training stimulus.

Stimulus generalization is a relative phenomenon: The more that stimulus conditions in the generalization setting resemble the stimulus conditions present during instruction, the greater the probability that the trained response will be emitted, and vice versa. A generalization setting that differs significantly from the instructional setting may not provide sufficient stimulus control over the target behavior. Such a setting may also contain stimuli that impede the target behavior because their novelty confuses or startles the learner. Exposing the learner to stimuli during instruction that are commonly found in the generalization setting increases the likelihood that those stimuli will acquire some stimulus control over the target behavior and also prepares the learner for the presence of stimuli in the generalization setting that have the potential of hindering performance. Two tactics used by applied behavior analysts to implement this basic strategy are program common stimuli and teach loosely.

Program Common Stimuli

Program common stimuli means incorporating typical features of the generalization setting into the instructional setting. Although behavior analysts have attached a special term to this tactic, successful practitioners in many fields have long used this technique for promoting generalized behavior change. For example, coaches (like Fresno State's Coach Hill), music teachers, and theater directors hold scrimmages, mock auditions, and dress rehearsals to prepare their athletes, musicians, and actors to perform important skills in settings that include the sights, sounds, materials, people, and procedures that simulate as closely as possible those in the "real world."

Van den Pol and colleagues (1981) programmed common stimuli when they taught three young adults with disabilities how to order and eat in fast-food restaurants. The researchers used numerous items and photos from actual restaurants to make the classroom simulate the conditions found in actual restaurants. Plastic signs with pictures and names of various McDonald's sandwiches were posted on the classroom wall, a table was transformed into a mock "counter" for role-playing transactions, and the students practiced responding to 60 photographic slides taken in actual restaurants showing examples of situations customers are likely to encounter.

Bord and colleagues (2017) provide an example of programming common stimuli when teaching ice skating to a child with autism. The researchers set up a rollerblading environment to simulate the local ice-skating rink by arranging large cones in the same-sized oval as the ice-skating rink. They also included common features, such as the presence of people (e.g., center, sidelines, no people), the direction of skating (i.e., clockwise, counterclockwise) across sessions, and the presence and absence of music.

Why go to all the trouble of simulating the generalization setting? Why not just conduct instruction in the generalization setting itself to ensure that the learner experiences all of the relevant aspects of the setting? First, conducting instruction in natural settings is not always possible or practical. The resources and time required to transport students to community-based settings may not be available.

Second, community-based training may not expose students to the full range of examples they are likely to encounter later in the same setting. For example, students who receive *in situ* instruction for grocery shopping or street crossing during school hours may not experience the long lines at the checkout counters or heavy traffic patterns typical of evening hours.

Third, instruction in natural settings may be less effective and efficient than classroom instruction because the trainer cannot halt the natural flow of events to contrive an optimal number and sequence of training trials needed (e.g., Neef, Lensbower, Hockersmith, DePalma, & Gray, 1990).

Fourth, instruction in simulated settings can be safer, particularly with target behaviors that must be performed in potentially dangerous environments or that have severe consequences if performed incorrectly (e.g., Miltenberger et al., 2005), or when children or people with learning problems must perform complex procedures. If the procedures involve invading the body or errors during practice are potentially hazardous, simulation training should be used. For example, Neef, Parrish, Hannigan, Page, and Iwata (1990) had children with neurogenic bladder complications practice performing self-catheterization skills on dolls.

Programming common stimuli is a two-step process of (a) identifying salient stimuli that characterize the generalization setting(s) and (b) incorporating those stimuli into the instructional setting. A practitioner can identify possible stimuli in the generalization setting to make common by direct observation or by asking people familiar with the setting. Practitioners should conduct observations in the generalization setting(s) and note prominent features of the environment that might be important to include during training. When direct observation is not feasible, practitioners can obtain secondhand knowledge of the setting by interviewing or giving checklists to people who have

firsthand knowledge of the generalization setting—those who live, work in, or are otherwise familiar with the generalization setting(s) in question.

When possible, practitioners should use the same reinforcers during instruction as those typically produced by the target behavior in the generalization environment. Once contacted in the natural environment, the reinforcers themselves may serve as a discriminative stimuli for the target behavior (e.g., Koegel & Rincover, 1977).

If a generalization setting includes important stimuli that cannot be re-created or simulated in the instructional setting, then at least some training trials must be conducted in the generalization setting. However, as pointed out previously, practitioners should not assume that community-based instruction will guarantee students' exposure to all of the important stimuli common to the generalization setting.

Teach Loosely

Applied behavior analysts control and standardize intervention procedures to maximize their direct effects, and so the effects of their interventions can be interpreted and replicated by others. Yet restricting teaching procedures to a "precisely repetitive handful of stimuli or formats may, in fact, correspondingly restrict generalization of the lessons being learned" (Stokes & Baer, 1977, p. 358). To the extent that generalized behavior change can be viewed as the opposite of strict stimulus control and discrimination, one technique for facilitating generalization is to vary as many of the noncritical dimensions of the antecedent stimuli as possible during instruction.

Teach loosely means randomly varying noncritical aspects of the instructional setting within and across teaching sessions. This tactic has two advantages or rationales for promoting generalization. First, teaching loosely reduces the likelihood that a single or small group of noncritical stimuli will acquire exclusive control over the target behavior. A target behavior that inadvertently comes under the control of a stimulus present in the instructional setting but not always present in the generalization setting may not be emitted in the generalization setting. Here are two examples of this type of faulty stimulus control:

- ***Following teachers' directions:*** A student with a history of receiving reinforcement for complying with teachers' directions when they are given in a loud voice and accompanied by a stern facial expression may not follow directions that do not contain one or both of those noncritical variables. The discriminative stimulus for the student's compliance with teacher directions should be the content of the teacher's statements.
- ***Assembling bicycle sprocket sets:*** A new employee at the bicycle factory inadvertently learns to assemble rear sprocket sets by putting a red sprocket on top of a green sprocket and a green sprocket on top of a blue sprocket because the sprocket sets on a particular bicycle model in production on the day she was trained were colored in that fashion. However, proper assembly of a sprocket set has nothing to do with the colors of the individual sprockets; the relevant variable is the relative size of the sprockets (i.e., the biggest sprocket goes on the bottom, the next biggest on top of that one, and so on).

Systematically varying the presence and absence of noncritical stimuli during instruction greatly decreases the chance that a functionally irrelevant factor—a teacher's tone of voice or sprocket color—will acquire control of the target behavior (Kirby & Bickel, 1988).

A second rationale for loose teaching is that including a wide variety of noncritical stimuli during instruction increases the probability that the generalization setting will include some of the stimuli that were present during instruction. In this sense, loose teaching acts as a kind of catchall effort at programming common stimuli and makes it less likely that a student's performance will be impeded or "thrown off" by the presence of a "strange" stimulus.

Loose teaching applied to the previous two examples might entail the following:

- ***Following teachers' directions:*** During instruction, the teacher varies all of the factors mentioned earlier (e.g., tone of voice, facial expression), plus gives directions while standing, while sitting, from different places within the classroom, at different times of the day, while the student is alone and in groups, while looking away from the student, and so on. In each instance, reinforcement is contingent on the student's compliance with the content of the teacher's direction irrespective of the presence or absence of any of the noncritical features.
- ***Assembling bicycle sprocket sets:*** During training, the new employee assembles sprocket sets containing sprockets of widely varying colors, after receiving the component sprockets in varied sequences, when the factory floor is busy, at different times during a work shift, with and without music playing, and so forth. Irrespective of the presence, absence, or values of any of these noncritical factors, reinforcement would be contingent on correct assembly of sprockets by relative size.

Seldom used as a stand-alone tactic, loose teaching is often a recognizable component of interventions when generalization to highly variable and diverse settings or situations is desired. For example, Horner and colleagues (1986) incorporated loose teaching into their training program for table busing by systematically but randomly varying the location of the tables, the number of people at the tables, whether food was completely or partially eaten, the amount and location of garbage, and so forth. Hughes and colleagues (1995) incorporated loose teaching by varying the peer teachers and varying the locations of training sessions. Loose teaching was evident in Bord and colleagues' (2017) study when they varied the genre (e.g., rock, classical, no music) and volume (e.g., 80 db, 60 db, 40 db) of music in the instructional setting to reflect the range of music the learner might encounter in the generalization setting. Loose teaching is often a recognizable feature of language training programs that use milieu, incidental, and naturalistic teaching methods (e.g., Charlop-Christy & Carpenter, 2000; McGee, Morrier, & Daly, 1999; Warner, 1992).

Few studies evaluating the effects of using loose teaching in isolation have been reported. One exception is an experiment by Campbell and Stremel-Campbell (1982), who evaluated the effectiveness of loose teaching as a tactic for facilitating the generalization of newly acquired language by two students with moderate cognitive disabilities. The students were taught the correct use of the words *is* and *are* in "wh" questions (e.g., "What are you doing?"), yes/no reversal questions (e.g., "Is this mine?"), and statements (e.g., "These are mine?"). Each student received two 15-min language training sessions conducted within the context of other instructional activities that were part of each child's individualized education program, one during an academic task and the second during a self-help task. The student could initiate a language interaction based on the wide variety of naturally occurring stimuli, and the teacher could try to evoke a statement or question from the student by intentionally misplacing instructional materials or offering indirect prompts. Generalization probes of the students' language use during two daily 15-min free-play periods revealed substantial generalization of the language structures acquired during the loose teaching sessions.

The learner's performance of the target behavior should be established under fairly restricted, simplified, and consistent conditions, before much "looseness" is introduced. This is particularly important when teaching complex and difficult skills. Only noncritical (i.e., functionally irrelevant) stimuli should be "loosened." Practitioners should not inadvertently loosen stimuli that reliably function in the generalization setting as discriminative stimuli (S^Ds) or as "don't do it" examples (S^Δs). Stimuli known to play important roles in signaling when and when not to respond should be systematically incorporated into instructional programs as teaching examples. A stimulus condition that may be functionally irrelevant for one skill may be a critical S^D for another skill.

Taking the notion of varying noncritical aspects of the instructional setting and procedures to its logical limit, Baer (1999) offered the following advice for loose teaching:

- Use two or more teachers.
- Teach in two or more places.
- Teach from a variety of positions.
- Vary your tone of voice.
- Vary your choice of words.
- Show the stimuli from a variety of angles, using sometimes one hand and sometimes the other.
- Have other persons present sometimes and not other times.
- Dress quite differently on different days.
- Vary the reinforcers.
- Teach sometimes in bright light, sometimes in dim light.
- Teach sometimes in noisy settings, sometimes in quiet ones.
- In any setting, vary the decorations, vary the furniture, and vary their locations.
- Vary the times of day when you and everyone else teach.
- Vary the temperature in the teaching settings.
- Vary the smells in the teaching settings.
- Within the limits possible vary the content of what's being taught.
- Do all of this as often and as unpredictably as possible. (p. 24)

Of course, Baer (1999) was not suggesting that a teacher needs to vary all of these factors for every behavior taught. But building a reasonable degree of "looseness" into teaching is an important element of a teacher's overall effort to program for generalization rather than train and hope.

Comparing Teach Enough Examples, Program Common Stimuli, and Teach Loosely. Teach enough examples, program common stimuli, and teach loosely are three related tactics for promoting generalized outcomes based upon the principle of stimulus control. Each strategy entails the systematic selection, presentation, and variation of antecedent stimuli during instruction. The definition and rationale for each tactic and examples of stimuli that might be included in a program to teach a novice driver how to parallel park are shown in Table 30.2.

The three tactics differ from one another on the basis of how critical a particular antecedent stimulus is to the target behavior and the specificity with which the stimulus is identified and controlled during instruction. The tactics can be compared and contrasted as illustrated in Figure 30.7. At one end of the importance and specificity continuum is *teach loosely*, a tactic in which noncritical stimuli are randomly varied during and across teaching sessions. At the other end lies *teach enough examples*, which requires the identification and precise presentation of instructional examples representing critical features found in the generalization setting/situation. Relatively speaking, *programming common stimuli* falls in the middle of the continuum and overlaps with the tactics on either side.

Judging where a given stimulus belongs on the importance continuum can be puzzling. When teaching parallel parking, should the amount and flow of traffic be incorporated into specific teaching examples or programmed as a common stimulus? Should passengers talking to the driver or one another be programmed as a common stimulus or varied among a collection of other noncritical stimuli as part of loose teaching? A good case could be made for either answer in both examples. That there are no right and wrong answers to these questions poses no hindrance to planning and delivering instruction for generalized behavior change. What is important is taking all potentially relevant stimuli into account. We recommend practitioners integrate stimuli that fall in the overlaps between these strategies with this conservative approach: Build stimuli that might be teaching examples or common stimuli into the instructional plan as specific teaching examples; program as common stimuli those that fall between program common stimuli and teach loosely.

Maximize Contact with Reinforcement in the Generalization Setting

Even though the learner emits a newly acquired target behavior in a generalization setting, generalization and maintenance will be short-lived if the behavior does not contact naturally existing contingencies of reinforcement. Five of the 13 tactics for promoting generalized behavior change described in this

TABLE 30.2 Teach Enough Examples, Program Common Stimuli, and Teach Loosely Compared

Strategy	Rationale	Examples: Teaching Parallel Parking
Teach enough examples—Select and teach examples representing the full range of critically relevant stimulus variations and response requirements typically found in the generalization setting.	To increase the likelihood of correct responses to untaught examples encountered in the generalization setting.	• Available parking spaces of different lengths • Parked car at front, back, or both ends of space • Driving own car, partner's car, rental car • In a hurry/late for appointment • "No Parking" sign or hood over parking meter • Passenger questioning or challenging driver's ability to parallel park
Program common stimuli—Include stimuli in the instructional setting that are known or are likely to exist in the generalization setting.	To increase the likelihood of setting/situation generalization.	• Heavy traffic, little or no traffic • One or more passengers in car • Pedestrians on sidewalk • Radio on/off • Daytime or at night
Teach loosely—Vary functionally irrelevant stimuli within and across teaching sessions.	To (a) minimize the likelihood of an irrelevant stimulus acquiring stimulus control over the target behavior and (b) program common stimuli to the extent the learner encounters any of the "loosened" stimuli in the generalization settings.	• Music, sports, or news on radio at different volumes • Passenger(s) talking to driver or one another • Weather: sun, rain, fog, snow • Expensive car(s) parked in front and/or back of space • Police officer or police car nearby

chapter involve some form of arranging or contriving for the target behavior to be reinforced in the generalization setting.

Teach Behavior to Levels Required by Natural Contingencies

Baer (1999) noted a common mistake by practitioners: failing to teach the behavior change to performance levels sufficient to meet natural contingencies of reinforcement.

> Behavior changes that seem to need generalization may only need better teaching. Try making the students fluent, and see if they still need further support for generalization. Fluency may consist of any or all of the following: high rate of performance, high accuracy of performance, fast latency given the opportunity to perform, and strong response. (p. 17)

A new behavior may occur in the generalization setting but fail to make contact with naturally existing contingencies of reinforcement. Ensuring that a new behavior change meets naturally existing contingencies of reinforcement may require enhancing the learner's performance of the target behavior in one or more of these dimensions: accuracy, rate, duration, latency, magnitude, and topography. For example, when given a worksheet to complete at his desk, a student's behavior that is consistent with the following dimensions is unlikely to contact reinforcement for completing the task, even if the student has the ability to complete each worksheet item accurately.

- ***Latency too long.*** A student who spends 5 minutes "daydreaming" before he begins reading the directions may not finish in time to obtain reinforcement.
- ***Rate too low.*** A student who needs 5 minutes to read the directions for an independent seatwork assignment that his peers read in less than 1 minute may not finish in time to obtain reinforcement.
- ***Duration too brief.*** A student who can work without direct supervision for only 5 minutes at a time will not be able to complete any task requiring more than 5 minutes of independent work.

The solution for this kind of generalization problem, while not always simple, is straightforward. Instruction must bring target behavior performance to levels commensurate with the

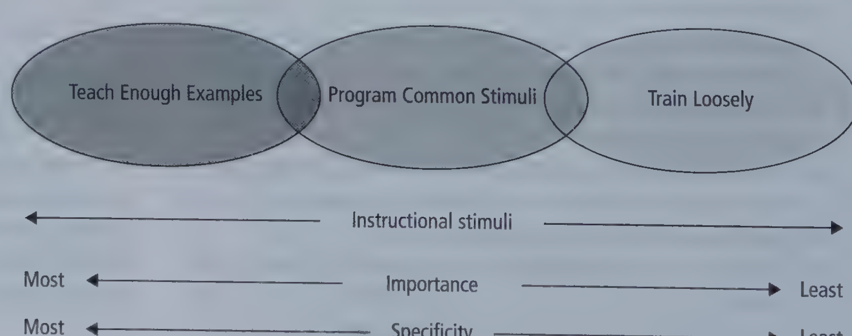

Figure 30.7 Relative importance and specificity of instructional stimuli selected for the generalization-promoting tactics: teach enough examples, program common stimuli, and teach loosely.

naturally occurring contingencies in the generalization setting. A good generalization plan specifies the performance necessary to meet naturally existing criteria for reinforcement.

Program Indiscriminable Contingencies

The clear, predictable, and immediate consequences that are so effective in helping learners acquire new behavior can work against generalized responding. This is most likely to occur when a newly acquired skill has not yet contacted naturally existing contingencies of reinforcement, and the learner can discriminate when the instructional contingencies are absent in the generalization settings. When the presence or absence of the controlling contingencies can be detected in the generalization setting ("The game's off, no need to respond here/now."), the learner may stop responding in the generalization setting, and the behavior change the practitioner worked so hard to develop may cease to occur before it can contact the naturally existing contingencies of reinforcement.

An **indiscriminable contingency** is one in which the learner cannot discriminate whether or not the next response will produce reinforcement. As a tactic for promoting generalization and maintenance, programming indiscriminable contingencies involves contriving a contingency in the generalization setting in which (a) reinforcement is contingent on some, but not all, occurrences of the target behavior, and (b) the learner is unable to predict which responses will produce reinforcement.

The basic rationale for programming indiscriminable contingencies is to keep the learner responding often enough and long enough in the generalization setting for the target behavior to make sufficient contact with the naturally existing contingencies of reinforcement. From that point on, the need to program contrived contingencies to promote generalization will be moot. Applied behavior analysts use two related techniques to program indiscriminable contingencies: intermittent schedules of reinforcement and delayed rewards.

Intermittent Schedules of Reinforcement. A newly learned behavior often must occur repeatedly over a period of time in the generalization setting before it contacts a naturally existing contingency of reinforcement. During that time, an extinction condition exists for responses emitted in the generalization setting. The current or most recent schedule of reinforcement for a behavior in the instructional setting plays a significant role in how many responses will be emitted in the generalization setting prior to reinforcement. Behaviors that have been under continuous schedules of reinforcement (CRF) show limited response maintenance under extinction. When reinforcement is no longer available, responding is likely to decrease rapidly to pre-reinforcement levels. In contrast, behaviors with a history of intermittent schedules of reinforcement often continue to be emitted for relatively long periods after reinforcement is no longer available (e.g., Dunlap & Johnson, 1985; Hoch, McComas, Thompson, & Paone, 2002).

Koegel and Rincover (1977, Experiment II) demonstrated the effects of intermittent schedules of reinforcement on response maintenance in a generalization setting. The participants were six boys diagnosed with autism and severe to profound cognitive disabilities, ages 7 to 12 years, who had participated in a previous study and had shown generalized responding in the extra-therapy setting used in that experiment (Rincover & Koegel, 1975). As in Experiment I by Koegel and Rincover (1977) described earlier in this chapter, one-on-one training trials were conducted with each child and the trainer seated at a table in a small room, and generalization trials were conducted by an unfamiliar adult standing outside on the lawn, surrounded by trees. The target behavior was (a) nonverbal imitation (e.g., raising arm) in response to an imitative model and the verbal instruction "Do this" and (b) touching a body part in response to verbal instructions such as "Touch your nose." After acquiring an imitation response, each child was given additional trials on one of three randomly chosen schedules of reinforcement: CRF, fixed ratio (FR) 2, or FR 5. After these additional training trials, each child was taken outside to assess response maintenance. Once outside, trials were conducted until the child's correct responding had decreased to 0% or maintained at 80% correct or above for 100 consecutive trials.

Behaviors that were most recently on a CRF schedule in the instructional setting underwent extinction quickly in the generalization setting (see Figure 30.8). Generalized responding occurred longer for the FR 2 trained behavior, and longer still for behavior that had been shifted to an FR 5 schedule in the instructional setting. The results showed clearly that the schedule of reinforcement in the instructional setting had a predictable effect on responding in the absence of reinforcement in the generalization setting: The thinner the schedule in the instructional setting, the longer the response maintenance in the generalization setting.

The defining feature of all intermittent schedules of reinforcement is that only some responses are reinforced, which means, of course, that some responses go unreinforced. One possible explanation for the maintenance of responding during periods of extinction for behaviors developed under intermittent schedules is the relative difficulty of discriminating that reinforcement is no longer available. Thus, the unpredictability of an intermittent schedule may account for the maintenance of behavior after the schedule is terminated.

Although *all indiscriminable contingencies of reinforcement involve intermittent schedules, not all schedules of intermittent reinforcement are indiscriminable.* For example, although the FR 2 and FR 5 schedules of reinforcement used by Koegel and Rincover (1977) were intermittent, many learners would soon be able to discriminate whether reinforcement would follow their next response. In contrast, a student whose behavior is being supported by a variable ratio (VR) 5 schedule of reinforcement cannot determine if his next response will be reinforced.

Delayed Rewards. Stokes and Baer (1977) suggested that not being able to discriminate the time when a behavior will be reinforced is similar to not being able to discriminate whether the next response will be reinforced. They cited an experiment by Schwarz and Hawkins (1970) in which each day after school a sixth-grade girl was shown videotapes of her behavior in that day's math class and received praise and token reinforcement for improvements in her posture, reducing the number of times she touched her face, and speaking with sufficient volume to be heard by others. Reinforcement after school was contingent

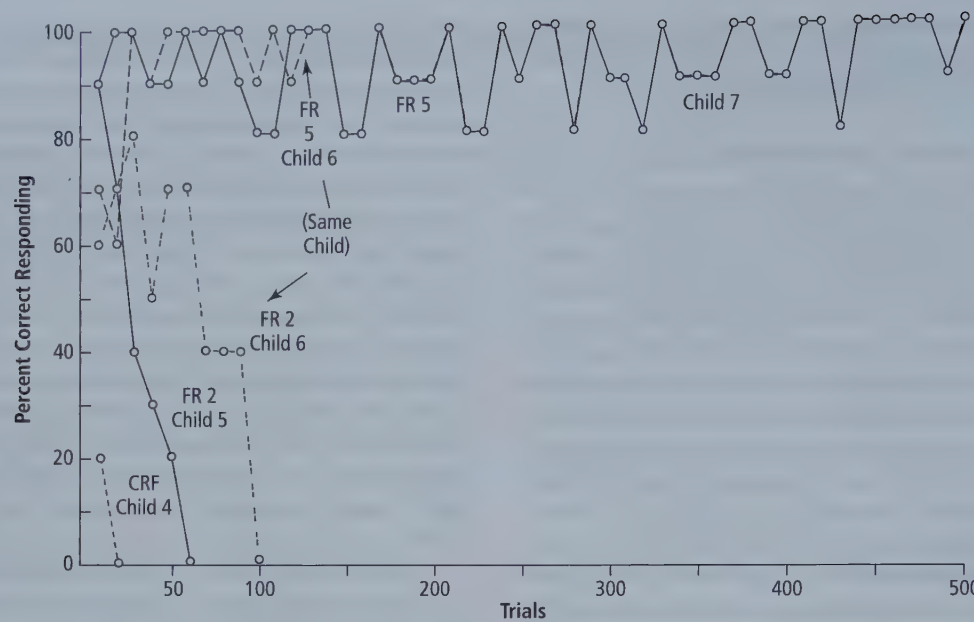

Figure 30.8 Percent of correct responses by three children in a generalization setting as a function of the schedule of reinforcement used during the final sessions in an instructional setting.

From "Research on the Differences between Generalization and Maintenance in Extra-Therapy Responding" by R. L. Koegel and A. Rincover, 1977, *Journal of Applied Behavior Analysis, 10,* p. 8. Reproduced with permission of John Wiley & Sons, Inc.

on behaviors emitted during math class only, but comparable improvements were noted in spelling class as well. The generalization data were taken from videotapes of the girl's behavior in spelling class and were never shown to her. Stokes and Baer hypothesized that because reinforcement was delayed (the behaviors that produced praise and tokens were emitted during math class but were not rewarded until after school), it may have been difficult for the student to discriminate when improved performance was required for reinforcement. They suggested that the generalization across settings of the target behaviors may have been a result of the indiscriminable nature of the response-to-reinforcement delay.

Delayed rewards and intermittent schedules of reinforcement are alike in two ways: (a) Reinforcement is not delivered each time the target behavior is emitted (only some responses are followed by reinforcement), and (b) there are no clear stimuli to signal which responses will produce reinforcement. Delayed reward contingencies differ from intermittent reinforcement in that instead of the consequence immediately following an occurrence of the target behavior, the reward is provided after a period of time has elapsed (i.e., a response-to-reward delay). Receiving the delayed reward is contingent on the learner having performed the target behavior in the generalization setting *during an earlier time period.* With an effective delayed reward contingency, the learner cannot discriminate when (and perhaps where, depending on the details of the contingency) the target behavior must be emitted to obtain a reward later. As a result, the learner's best chance to receive the reward later is to "be good all day" (Fowler & Baer, 1981).

Two similar studies by Freeland and Noell (1999, 2002) investigated the effects of delayed rewards on the maintenance of students' mathematics performance. Participants in the second study were two third-grade girls who had been referred by their teacher for help with mathematics. That target behavior for both students was writing answers to single-digit addition problems with sums to 18. The researchers used a multiple-treatment reversal design to compare the effects of five conditions on the number of correct digits written as answers to single-digit addition problems during daily 5-min work periods (e.g., writing "11" as the answer to "5 + 6 = ?" counted as two digits correct).

- *Baseline:* Green worksheets; no programmed consequences. Students were told they could attempt as many or as few problems as they wanted.
- *Reinforcement:* Blue worksheets with a goal number at the top indicating the number of correct digits needed to choose a reward from the "goody box." Each student's goal number was the median number of correct digits on the last three worksheets. All worksheets were graded after each session, and reinforcement was contingent on meeting the performance goal.
- *Delay 2:* White worksheets with goal number; after every two sessions, one of the two worksheets completed by each student was randomly selected for grading; reinforcement was contingent on meeting highest median of three consecutive sessions up to that point in the study.
- *Delay 4:* White worksheets with goal number and same procedures as Delay 2 except that worksheets were not graded until four sessions had been completed, at which time one of each student's previous four worksheets was randomly selected and graded.

- *Maintenance:* White worksheets with goal number as before; no worksheets were graded and no feedback or rewards for performance were given.

The different-colored worksheets used for each condition in this study made it easy for the students to predict the likelihood of reinforcement. A green worksheet meant no feedback or other consequences no matter how many correct digits were written. A blue worksheet indicated that meeting the performance goal would earn a reward from the "goody box." However, meeting the performance criterion on a white worksheet sometimes produced reinforcement. This study demonstrates the importance of having contingencies in the instructional setting "look like" the contingencies in effect in the generalization setting(s) in two ways: (a) Both students showed large decreases in performance when baseline conditions were reinstated, and stopped responding altogether during a second return to baseline; and (b) the students continued completing math problems at a high rate during the maintenance condition, even though no reinforcement was provided (see Figure 30.9).

When the delayed (indiscriminable) contingencies were implemented, both students demonstrated levels of correct responding at or above levels during the reinforcement phase. When the students were exposed to maintenance conditions, Amy maintained high levels of responding for 18 sessions with variable performance over the final six sessions, and Kristen showed a gradually increasing rate of performance over 24 sessions. The results demonstrated that behavior with an indiscriminable contingency can be maintained at the same rate as with a predictable schedule, and with greater resistance to extinction.

Delayed consequences have been used to promote the setting/situation generalization and response maintenance of a wide range of target behaviors, including academic and vocational tasks by individuals with autism (Dunlap, Koegel, Johnson, & O'Neill, 1987); young children's toy play, social initiations, and selection of healthy snacks (R. A. Baer, Blount, Dietrich, & Stokes, 1987; R. A. Baer, Williams, Osnes, & Stokes, 1984; Osnes, Guevremont, & Stokes, 1986); restaurant trainees' responding appropriately to coworkers' initiations (Grossi et al., 1994); and performance on academic tasks (Brame, 2001; Theodore, Bray, Kehle, & Jenson, 2001).

Effective use of delayed consequences can reduce (or even eliminate in some instances) the learner's ability to discriminate when a contingency is or is not in effect. As a result, the learner needs to "be good" (i.e., emit the target behavior) all the time. If an effective contingency can be made indiscriminable across

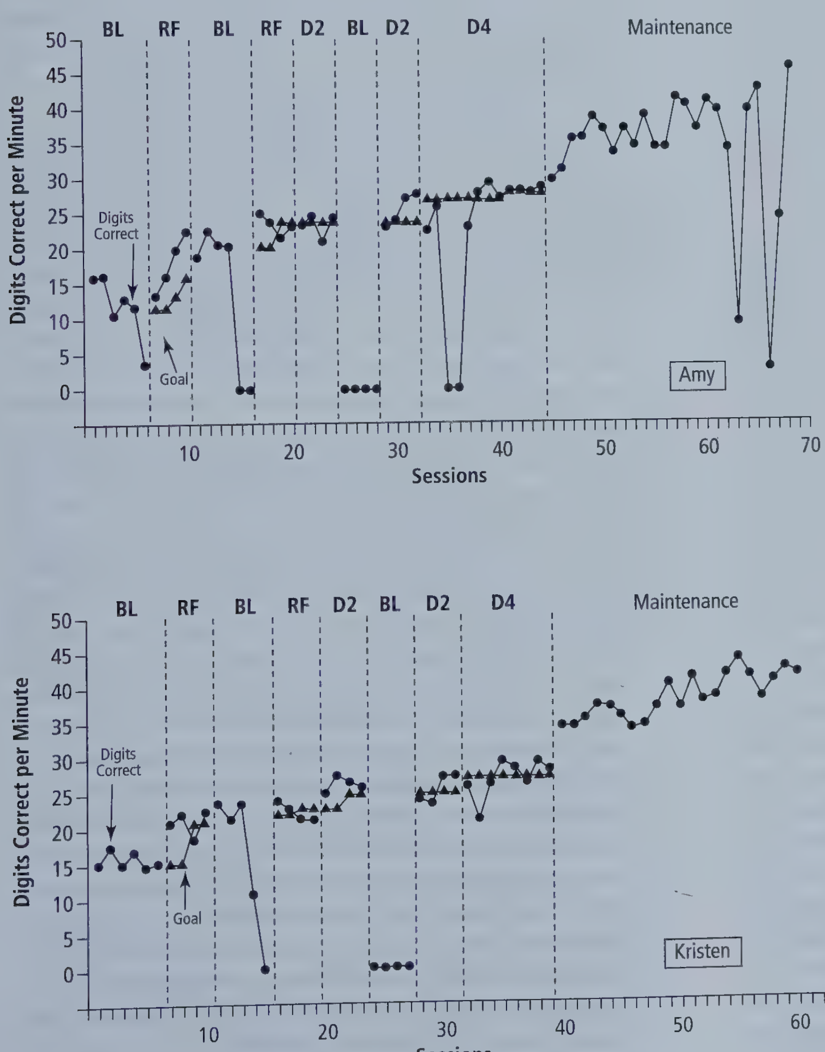

Figure 30.9 Number of correct digits per minute by two third-grade students while answering math problems during baseline (BL), reinforcement contingent on meeting the performance goal on one randomly selected worksheet after each session (RF), reinforcement contingent on meeting the performance goal on one randomly selected worksheet after every two (D2) or four (D4) sessions, and maintenance conditions.

From "Programming for Maintenance: An Investigation of Delayed Intermittent Reinforcement and Common Stimuli to Create Indiscriminable Contingencies," by J. T. Freeland and G. H. Noell, 2002, *Journal of Behavioral Education, 11*, p. 13. Copyright 2002 by Human Sciences Press. Reprinted by permission.

settings and target behaviors, the learner will also have to "be good" everywhere, with all of his or her relevant skills.

Here are two examples of how the supervisor of an office cleaning crew could use an indiscriminable contingency to reinforce quality work by an employee.

- At shift's end, the employee pulls from the supervisor's hat a slip of paper on which a room number and item to be cleaned are written (e.g., #566, carpet vacuumed). If the randomly selected item has been cleaned properly, the employee earns a reward.
- The employee initials and leaves a sticky note on the door of each room she has cleaned. The supervisor collects the notes and initials those from properly cleaned rooms. At shift's end, the employee draws a sticky-note from all the notes she left during that shift. If the randomly drawn note contains the supervisor's initials, she gets a reward.

Following are five examples of classroom applications of indiscriminable contingencies involving delayed rewards. Each application features an interdependent group contingency that makes group rewards contingent on the performance of randomly selected students (see Chapter 28).

- *Spinners and Dice I.* Teachers can make academic seatwork periods more effective with spinners and dice. Every few minutes (e.g., on a variable interval [VI] 5-min schedule), the teacher (a) randomly selects a student's name, (b) walks to that student's desk and has the student twirl a spinner or roll a die, (c) counts backward from the worksheet problem or item the student is currently working on by the number shown on the spinner or die, and (d) gives a token to the student if that problem or item is correct. Students who immediately begin to work on the assignment and work quickly but carefully throughout the seatwork period are most likely to obtain reinforcers under this indiscriminable contingency.
- *Spinners and Dice II.* In a study by L. D. Heward, Park, and Alber-Morgan (2008), second-graders completed a variety of academic tasks on the board. At the end of the timed work session, one student spun a spinner that determined the subject area (reading, time telling, social studies, or language). A second student then rolled dice that indicated the item number. Each student who correctly answered the randomly selected item earned a reward.
- *Story Fact Recall Game.* Many elementary teachers devote 20 to 30 minutes per day to sustained silent reading (SSR), a period when students can read silently from books of their choice (Temple, Ogle, Crawford, & Freppon, 2018). An indiscriminable contingency can encourage students to read with purpose during SSR. At the end of the SSR period, the teacher asks several randomly selected students a question about the book they are reading. A student reading Chapter 3 of Elizabeth Winthrop's *The Castle in the Attic* might be asked, "What did William give the Silver Knight to eat?" (Answer: bacon and toast). Correct answers are praised by the teacher, are applauded by the class, and earn a marble in a jar toward a reward for the whole class. Students do not know when they will be called on or what they might be asked (Brame, Heward, & Bicard, 2002).
- *The Jars.* The teacher arranges three jars containing slips of paper or cards indicating different behaviors, performance criteria, and rewards. At the conclusion of a preannounced time, the teacher randomly selects from one jar the subject area (e.g., math, science, social studies) or classroom rule (e.g., participation, no talk-outs), from a second jar the performance criteria (e.g., 70%, 80%, or 90% accuracy; 10, 15, or 20 problems completed), and from a third jar the reward to be earned if the performance criterion is met. A fourth jar might include names of individual students or subgroups within the class who must meet the performance criterion for the class to earn the reward. Several studies have found "the jars" to be a fun and effective method to improve and generalize students' academic performance and compliance with classroom rules (e.g., Kelshaw-Levering, Sterling-Turner, Henry, & Skinner, 2000; Theodore et al., 2001; Zibreg Hargis, Pattie, Maheady, Budin, & Rafferty, 2017).
- *Numbered Heads Together.* Having small groups of students work together on a joint learning activity can be effective, but teachers should use procedures that motivate all students to participate. A collaborative learning technique called Numbered Heads Together ensures that all students actively participate (Hunter et al., 2015; Kagan & Kagan, 2009). Students are seated in heterogeneous groups of three or four, and each student is given the number 1, 2, 3, or 4. The teacher asks the class a question, and each group discusses the problem and comes up with an answer. Next, the teacher randomly selects a number from 1 to 4 and then calls on one or more students with that number to answer. It is important that every person in the group knows the answer to the question. This strategy promotes cooperation within the group rather than competition. Because all students must know the answer, group members help each other understand not only the answer but also the how and why behind it. Finally, this strategy encourages individual responsibility.
- *Intermittent Grading.* Most students do not receive sufficient practice writing, and when students do write, the feedback they receive is often ineffective. One reason for this may be that providing detailed feedback on a daily composition by each student in the class requires more time and effort than even the most dedicated teacher can give. A procedure called *intermittent grading* offers one solution to this problem (Heward, Heron, Gardner, & Prayzer, 1991). Students write for 10 to 15 minutes each day, but instead of reading and evaluating every student's paper, the teacher provides detailed feedback on a randomly selected 20% to 25% of students' daily compositions. The students whose papers were graded earn points based on individualized performance criteria, and bonus points are given to the class contingent on the quality of the selected and graded papers (e.g., if the authors of four of the five papers that were graded met their individual criteria). Students' papers that were graded can be used as a source of instructional examples for the next lesson.

The effectiveness of a delayed reward tactic in promoting generalization and maintenance rests on (a) the indiscriminability of the contingency (i.e., the learner cannot tell exactly when emitting the target behavior in the generalization setting will produce a reward at a later time) and (b) the learner understanding the relation between emitting the target behavior and receiving a reward at a later time for doing so. Box 30.2 describes how indiscriminable contingencies can be used to foster sustainable practices such as recycling and energy conservation.

Guidelines for Programming Indiscriminable Contingencies. Practitioners should consider these guidelines when implementing indiscriminable contingencies:

- Use continuous reinforcement during the initial stages of developing new behaviors or when strengthening little-used behaviors.
- Systematically thin the schedule of reinforcement based on the learner's performance (see Chapter 13). Remember that the thinner the schedule of reinforcement is, the more indiscriminable it is (e.g., an FR 8 schedule is more indiscriminable than an FR 2 schedule); and variable schedules of reinforcement (e.g., VR and VI schedules) are more indiscriminable than fixed schedules are (e.g., FR and fixed interval [FI] schedules).
- When using delayed rewards, begin by delivering the reinforcer immediately following the target behavior and gradually increase the response-to-reinforcement delay.
- Each time a delayed reward is delivered, explain to the learner that he is receiving the reward for specific behaviors he performed earlier. This helps to build and strengthen the learner's understanding of the rule describing the contingency. A delayed rewards intervention may not be effective with some learners who have significant intellectual disabilities.

Set Behavior Traps

Some contingencies of reinforcement are especially powerful, producing substantial and long-lasting behavior changes. Baer and Wolf (1970b) called such contingencies **behavior traps**. Using a mouse trap as an analogy, they described how a householder has only to exert a relatively small amount of behavioral control over the mouse—getting the mouse to smell the cheese—to produce a behavior change with considerable (in this case, complete) generalization and maintenance.

> A householder without a trap can, of course, still kill a mouse. He can wait patiently outside the mouse's hole, grab the mouse faster than the mouse can avoid him, and then apply various forms of force to the unfortunate animal to accomplish the behavioral change desired. But this performance requires a great deal of competence: vast patience, super-coordination, extreme manual dexterity, and a well-suppressed squeamishness. By contrast, a householder with a trap needs very few accomplishments: If he can merely apply the cheese and then leave the trap where the mouse is likely to smell that cheese, in effect he has guaranteed general(ized) change in the mouse's future behavior.
>
> The essence of a trap, in behavioral terms, is that *only a relatively simple response is necessary to enter the trap, yet once entered, the trap cannot be resisted in creating general behavior change*. For the mouse, the entry response is merely to smell the cheese. Everything proceeds from there almost automatically. (p. 321, emphasis added)

Behavioral trapping is a fairly common phenomenon that everyone experiences from time to time. Behavior traps are particularly evident in the activities students just cannot get (or do) enough of. The most effective behavior traps share four essential features: (a) They are "baited" with virtually irresistible reinforcers that "lure" the student to the trap; (b) only a low-effort response already in the student's repertoire is necessary to enter the trap; (c) interrelated contingencies of reinforcement inside the trap motivate the student to acquire, extend, and maintain targeted academic and/or social skills; and (d) they can remain effective for a long time because students show few, if any, satiation effects.

Consider the case of the "reluctant bowler." A young man is persuaded to fill in as a substitute for a friend's bowling team. He has always regarded bowling as uncool. And bowling looks so easy on television that he does not see how it can be considered a real sport. Nevertheless, he agrees to go, just to help out this one time. During the evening he learns that bowling is not as easy as he had always assumed (he has a history of reinforcement for athletic challenges) and that several people he would like to get to know are avid bowlers (i.e., it is a mixed doubles league). Within a week he has purchased a custom-fitted bowling ball, a bag, and shoes; practiced twice on his own; and signed up for the next league.

The reluctant bowler example illustrates the fundamental nature of behavior traps: easy to enter and difficult to exit. Some naturally existing behavior traps can lead to maladaptive behaviors, such as alcoholism, drug addiction, and juvenile delinquency. The everyday term *vicious circle* refers to the natural contingencies of reinforcement that operate in destructive behavior traps. Practitioners, however, can learn to create behavior traps that help students develop positive, constructive knowledge and skills. Alber and Heward (1996) provided guidelines for creating successful traps and gave the following example of an elementary teacher creating a behavior trap that took advantage of a student's penchant for playing with baseball cards.

> Like many fifth graders struggling with reading and math, Carlos experiences school as tedious and unrewarding. With few friends of his own, Carlos finds that even recess offers little reprieve. But he does find solace in his baseball cards, often studying, sorting and playing with them in class. His teacher, Ms. Greene, long ago lost count of the number of times she had to stop an instructional activity to separate Carlos and his beloved baseball cards. Then one day, when she approached Carlos' desk to confiscate his cards in the middle of a lesson on alphabetization, Ms. Greene discovered that Carlos had already alphabetized all the left-handed pitchers in the National League! Ms. Greene realized she'd found the secret to sparking Carlos' academic development.

BOX 30.2

Fostering Earth-friendly Behavior with Clueless Contingencies

Earth's average temperature in 2016 was the warmest ever recorded, and when 2019 began, the ten warmest years on record had all occurred since 1998 (National Aeronautics and Space Administration [NASA], 2019; National Oceanic and Atmospheric Administration [NOAA], 2019). This global warming has contributed to melting ice sheets and rising sea levels, an increased frequency of catastrophic floods, droughts, and forest fires, and has threatened the survival of some species (Intergovernmental Panel on Climate Change, 2018). Most of the warming results from increased concentrations of carbon dioxide (CO_2) and other greenhouse gases in the atmosphere due to human activity since the mid-20th century, primarily the burning of fossil fuels (Intergovernmental Panel on Climate Change, 2014).

Although some climate change deniers persist in complete disregard of scientific facts, the challenge has shifted from convincing people climate change is real to getting them to change their behavior in response to it (Thompson, 2010). Even if all fossil fuel emissions ceased today, our climate would continue warming for decades (Marcott, Shakun, Clark, & Mix, 2013). Successfully adapting to that reality will require massive shifts to renewable energy sources and changes in transportation infrastructure, food production, environmental conservation, and economic practices on a global scale far beyond the behavior changes any of us can make now. But the changes we do make now can provide a *behavioral wedge* that gives society time to discover the technological fixes and implement the policy changes needed to make realities of carbon neutrality and a truly sustainable society (Dietz, Gardner, Gilligan, Stern, & Vandenbergh, 2009).

Rewarding Green Behavior

Richard Thaler (2012), economist and co-author of *Nudge: Improving Decisions About Health, Wealth, and Happiness*, began a *New York Times* essay, "Making Good Citizenship Fun," as follows: "Governments typically use two tools to encourage citizens to engage in civic behavior like paying their taxes, driving safely, or recycling their garbage: exhortation and fines. These efforts are often ineffective. So it might be a good time to include positive reinforcement." Thaler then described several examples of reinforcement-based government campaigns to promote behavior that many people avoid, including obeying the speed limit in Sweden, paying taxes in China, and picking up dog feces off the sidewalks in Taiwan.

Behavior analysts should be delighted that efforts to reward good behavior are catching on as a way to ameliorate social problems. Lotteries and related incentive systems are practically effective and conceptually consistent with behavioral principles. The overall impact of most such programs, however, is limited by a restricted footprint (limited setting, reward a single type of green behavior, reward individuals,) and predictability: "The game's off. No need to respond now."

An indiscriminable contingency approach to enhancing existing green initiatives can be designed, either for individuals or groups, to address multiple responses in many settings with many rewards. A green behavior change program featuring a well-designed indiscriminable contingency presents a radically different and enticing "if-then" contingency: When you can't tell which of several green behaviors performed exactly where or when will produce a reward, the best strategy for optimizing reward is acting green in every way, everywhere, all the time.

Let's Play Conservation Clue

Conservation Clue is a whodunit competition like the classic board game Clue™, but instead of trying to evade getting caught, players leave clues of their good green deeds all over the place. Examples of target behaviors, measures, rewards, and gaming fun that could be part of Conservation Clue games played in residential, work, and community settings are shown in Figure A.

1. **Target Green Behaviors.** Select oft-repeated behaviors such as turning off lights, unplugging electronics, or taking public transit. Once-only behaviors such as buying a plug-in hybrid or installing solar panels do not lend themselves to this approach (though they can be incentivized in other ways; see Chance & Heward, 2010).
2. **Determine How to Detect and Measure the Behaviors.** Some behaviors leave products that are readily measured, such as the number of outlets or bulbs in use, or the weight or volume in a recycle bin. Other behaviors must be recorded as they occur, such as punches on a bus pass or tickets dispensed for bringing a reusable bag. Recruiting people to monitor and measure green actions can pay off with additional prompts, modeling, or incidental social reinforcement for the targeted behaviors. Members of student or community groups with environmental and sustainability missions would gladly serve as "Conservation Clue Detectives."
3. **Ready the Playing Field.** Just as athletes play better on a well-groomed diamond or rink, Conservation Clue gamers will behave greener in well-prepared environments. Preparation entails two primary actions: minimizing barriers to responding (e.g., putting recycling bins where they are easy to access) and alerting participants to the opportunity to play (in other words, providing prompts to engage in green behavior).
4. **Select Rewards.** Examples of simple, relatively inexpensive rewards for a campus-based game of Conservation Clue include school insignia wear, bookstore discounts, lunch with the dean, concert tickets, and gift certificates for local green businesses. Virtual objects such as stars, trophies, and green leaves that gamers receive and collect online can be effective and fun rewards (Pritchard, 2010; Twyman, 2010).

Settings	 **Where We Live**	 **Where We Work**	 **Where We Shop**
Behaviors	• unplug • reduce water use • reduce heat and A/C • reduce solid waste (recycle & compost) • reuse containers	• recycle paper/waste • carpool/take public transportation • power down idle equipment • use vehicles efficiently • reuse materials	• buy locally sourced food and goods • buy products in bulk or reduced packaging • buy items made with recycled content • shop with reusable bags
Measures	• plugs in use • bulb counts • utility bills • meter readings • weight of recyclables • purchase receipts	• public transit receipts • GPS data from fleet vehicles • employees initial reused materials • green officer verification	• store receipts • bar code scans • cashier verification
Rewards	• discounts at local shops • recycle bin stickers • utility bill discounts • point accrual • virtual rewards	• recognition • extra breaks • lunch with the boss • company gear • cash bonuses	• reduced cost items • gift cards • charity donations in shopper's name • electronic fanfare • public posting
The Game	• jar drawings • dice rolls • dart throws 	• spinners • wheels of chance • lotteries 	• random item on sales receipts half-off • raffles 
Figure A Target behaviors, measures, rewards, and game methods that could be used in Conservation Clue, played where we live, work, and shop.

5. **Make It a Game.** The centerpiece of Conservation Clue is a game-like procedure for randomly determining which green behaviors, emitted where and when, will earn what rewards. The jars technique described earlier is one of countless ways of implementing this multidimensional indiscriminable contingency. Game rules and materials—spinners or dice or dart boards—should be selected to suit the setting and players' interests; the crucial element is that multiple forms of green behavior are rewarded in a way that is utterly unpredictable . . . and fun.

(continued)

BOX 30.2 (continued)

6. **Evaluate, Revise, and Play Again.** In the spirit of the science from which it is derived, Conservation Clue should be an empirical endeavor. Gather baseline data on target behaviors against which to compare any gains that subsequently come as a result of the playing. The game includes many variables to monitor and experiment with, such as which green behaviors are more malleable, which rewards are more preferred, and what time intervals between drawings are optimal. Player satisfaction should be assessed and suggestions for improvements sought.

Conservation Clue is one way to back good intentions with consequential muscle. The behavior changes may seem trivial at first. But many small actions can redefine what it means to act locally and have global impact. Imagine Conservation Clue being played by the residents of London or Shanghai, drivers on the New Jersey Turnpike, or employees of a major corporation with a global footprint. What if Walmart's more than 2 million employees at the company's 4253 stores around the globe engaged in a full-fledged game of Conservation Clue? What if they then invited the 200 million customers who shop at their stores each week to join in the fun?

Adapted from "Sustaining Sustainability with Clueless Contingencies," by W. L. Heward and J. W. Kimball, 2013, *Sustain Magazine*, *28*, 4–15. Used with permission.

Carlos was both astonished and thrilled to learn that Ms. Greene not only let him keep his baseball cards at his desk, but also encouraged him to "play with them" during class. Before long, Ms. Greene had incorporated baseball cards into learning activities across the curriculum. In math, Carlos calculated batting averages; in geography, he located the hometown of every major leaguer born in his state; and in language arts, he wrote letters to his favorite players requesting an autographed photo. Carlos began to make significant gains academically and an improvement in his attitude about school was also apparent.

But school became really fun for Carlos when some of his classmates began to take an interest in his knowledge of baseball cards and all the wonderful things you could do with them. Ms. Greene helped Carlos form a classroom Baseball Card Club, giving him and his new friends opportunities to develop and practice new social skills as they responded to their teacher's challenge to think of new ways to integrate the cards into the curriculum. (p. 285)

Ask People in the Generalization Setting to Reinforce the Target Behavior

The problem may be simply that the natural community [of reinforcement] is asleep and needs to be awakened and turned on.

—Donald M. Baer (1999, p. 16)

Sometimes a potentially effective contingency of reinforcement in the generalization setting is not operating in a form available to the learner no matter how often or well she performs the target behavior. The contingency is there, but dormant. One solution for this kind of problem is to inform key people in the generalization setting of the value and importance of their attention to the learner's efforts to acquire and use new skills and ask them to help.

For example, a special education teacher who has been helping a student learn how to participate in class discussions by providing repeated opportunities for practice and feedback in the resource room could inform the teachers in the general education classes that the student attends about the behavior change program and ask them to look for and reinforce any reasonable effort by the student to participate in their classrooms. A small amount of contingent attention and praise from these teachers may be all that is needed to achieve the desired generalization of the new skill.

This simple but often effective technique for promoting generalized behavior was evident in the study by Stokes and colleagues (1974) in which staff members responded to the children's waving response by saying, "Hello, (name)." Approximately 20 such generalization probes were conducted each day with each child.

Williams, Donley, and Keller (2000) gave mothers of two preschool children with autism explicit instructions on providing models, response prompts, and reinforcement to their children who were learning to ask questions about hidden objects (e.g., "What's that?" "Can I see it?").

Contingent praise and attention from significant others can add to the effectiveness of other strategies already in place in the generalization environment. Broden, Hall, and Mitts (1971) showed this in the self-monitoring study described in Chapter 29. After self-recording had improved eighth-grader Liza's study behavior during history class, the researchers asked Liza's teacher to praise Liza for study behavior whenever he could during history class. Liza's level of study behavior during this Self-Recording Plus Praise condition increased to a mean of 88% and was maintained at levels nearly as high during a subsequent Praise Only condition (see Figure 29.3).

Teach the Learner to Recruit Reinforcement

Another way to "wake up" a potentially powerful but dormant natural contingency of reinforcement is to teach the learner to recruit reinforcement from significant others. For example, Seymour and Stokes (1976) taught delinquent girls to work more productively in the vocational training area of a residential institution. However, observation showed that staff at the institution gave the girls no praise or positive interaction regardless of the quality of their work. The much-needed natural community of reinforcement to ensure the generalization of the girls' improved work behaviors was not functioning. To get around

this difficulty, the experimenters trained the girls to use a simple response that called the attention of staff members to their work. With this strategy, staff praise for good work increased. Thus, teaching the girls an additional response that could be used to recruit reinforcement enabled the target behavior to contact natural reinforcers that would extend and maintain the desired behavior change.

Students of various ages and abilities have learned to recruit teacher and peer attention in classroom and community settings: preschoolers with developmental delays for completing preacademic tasks and staying on task during transitions (Connell, Carta, & Baer, 1993; Stokes, Fowler, & Baer, 1978); and elementary and secondary students with learning disabilities (Alber, Heward, & Hippler, 1999; Wolford, Alber, & Heward, 2001), behavioral disorders (Alber, Anderson, Martin, & Moore, 2004; Morgan, Young, & Goldstein, 1983), and cognitive disabilities (Mank & Horner, 1987; Rouse, Everhart-Sherwood, & Alber-Morgan, 2014) who need help completing various academic and social tasks and improving vocational skills. A study by Craft, Alber, and Heward (1998) provides a representative example of this research.

Craft and colleagues (1998) assessed the effects of recruitment training on academic assignments for which students recruited teacher attention. Four elementary students were trained by their special education teacher (the first author) when, how, and how often to recruit teacher attention in the general education classroom. Training consisted of modeling, role playing, error correction, and praise in the special education classroom. The students were taught to show their work to the teacher or ask for help 2 to 3 times per session, and to use appropriate statements such as "How am I doing?" or "Does this look right?"

Data on the frequency of student recruiting and teacher praise statements were collected during a daily 20-min homeroom period in a general education classroom. During this period, the general education students completed a variety of independent seatwork tasks (reading, language arts, math) assigned by the general education teacher, while the four special education students completed spelling worksheets assigned by the special education teacher, an arrangement that had been established prior to the experiment. If students needed help with their assignments during homeroom, they took their work to the teacher's desk and asked for help.

The effects of recruitment training on the children's frequency of recruiting and on the number of praise statements they received from the classroom teacher are shown in Figure 30.10. Recruiting across students increased from a mean rate of 0.01 to 0.8 recruiting response per 20-min session during baseline to a mean rate of 1.8 to 2.7 after training. Teacher praise statements received by the students increased from a mean rate of 0.1 to 0.8 praise statement per session during baseline to a mean rate of 1.0 to 1.7 after training. The ultimate meaning and outcome of the intervention was in the increased amount and accuracy of academic work by each student (see Figure 6.8).

For a review of research on recruiting and suggestions for teaching children to recruit reinforcement from significant others, see Alber and Heward (2000). Box 30.3: "Look, Teacher, I'm All Finished!" provides suggestions for teaching students to recruit teacher attention.

Mediate Generalization

Another strategy for promoting generalized behavior change is to arrange for some thing or person to act as a medium that ensures the transfer of the target behavior from the instructional setting to the generalization setting. Two tactics for implementing this strategy are contriving a mediating stimulus and teaching the learner to mediate her own generalization through self-management.

Contrive a Mediating Stimulus

One tactic for mediating generalization is to bring the target behavior under the control of a stimulus in the instructional setting that will function in the generalization setting to reliably prompt or aid the learner's performance of the target behavior. The stimulus selected for this important role may exist already in the generalization environment, or it may be a new stimulus added to the instructional program that subsequently goes with the learner to the generalization setting. Whether it is a naturally existing component of the generalization setting or an added element to the instructional setting, to effectively mediate generalization, a **contrived mediating stimulus** must be (a) made functional for the target behavior during instruction and (b) easily transported to the generalization setting (Baer, 1999). The mediating stimulus is *functional* for the learner if it reliably prompts or aids the learner in performing the target behavior; the mediating stimulus is *transportable* if it easily goes with the learner to all important generalization settings.

Naturally existing features of generalization settings that are used as contrived mediating stimuli may be physical objects or people. Van den Pol and colleagues (1981) used paper napkins, a common feature of any fast-food restaurant, as a contrived mediating stimulus. They taught students that a paper napkin was the only place to put food. In this way, the researchers eliminated the added challenge and difficulty of teaching the students to discriminate clean tables from dirty tables, to sit only at clean tables, or to wipe dirty tables, and then programming the generalization and maintenance of those behaviors. By contriving the special use of the napkin, only one response had to be trained, and napkins then served as a mediating stimulus for that behavior.

Cariveau and Kodak (2017) contrived a common stimulus to promote the generalization and maintenance of academic engagement by second-graders during small-group writing and writing lessons. At the start of each lesson during intervention, the instructor placed in front of the students a yellow paper with a numeral written on it representing a performance goal (e.g., 8 indicated a goal of academic engagement for 80% of the session). At the end of each lesson, if a randomly selected student met the performance criterion, the entire group earned a reward. After a reversal design demonstrated a functional relation between the intervention and increased academic engagement, the researchers implemented a maintenance condition that incorporated the common stimulus. "The instructor placed the yellow card with a goal written on it (i.e., the common stimuli) in view of all participants and said, 'This is your goal for today.' At the end of each session, the instructor did not provide information about whether the participants met their goal and did not deliver reinforcement." (p. 126)

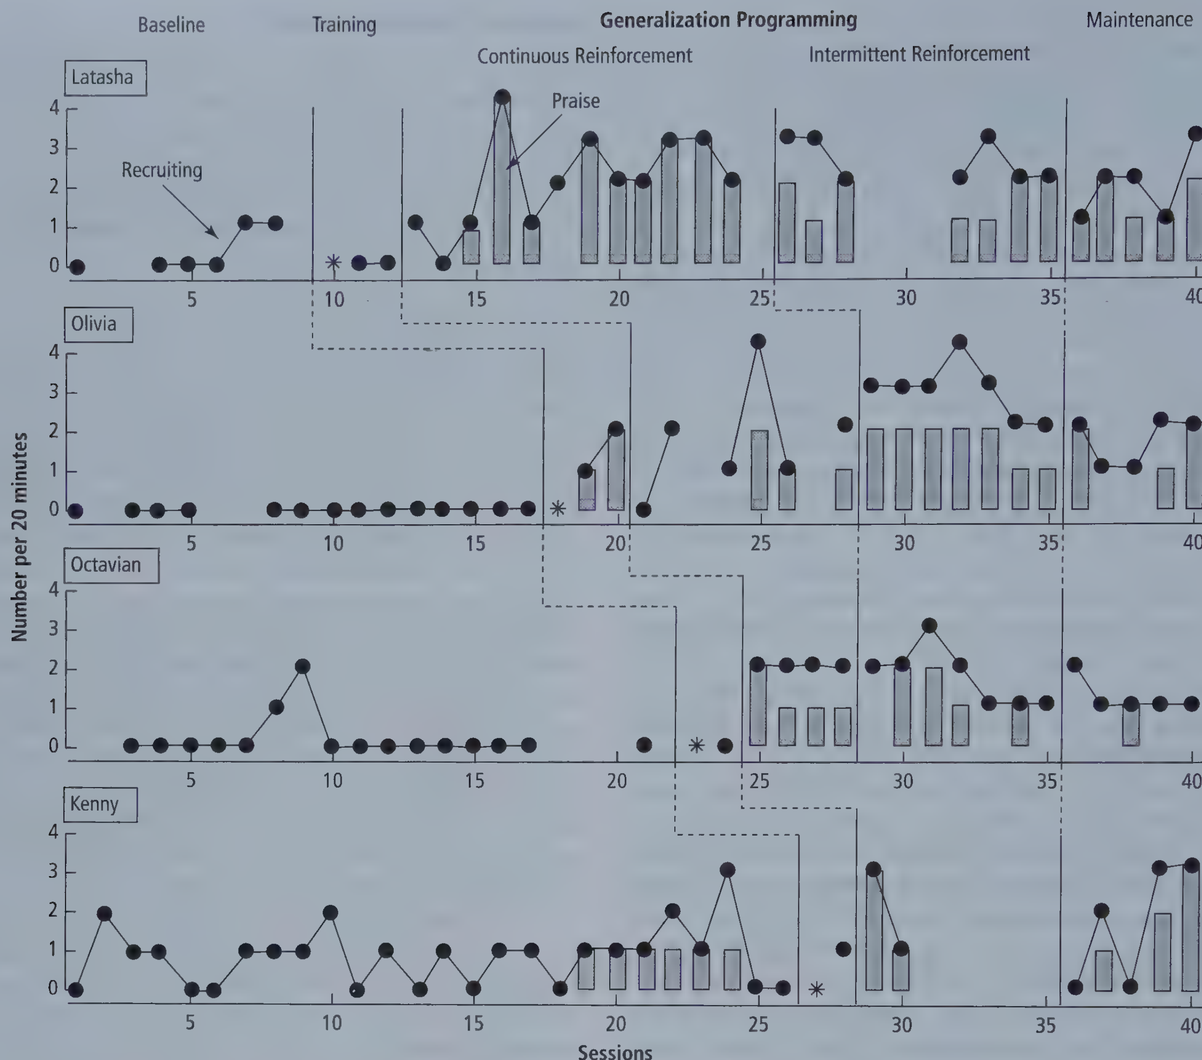

Figure 30.10 Number of recruiting responses (data points) and teacher praise statement (bars) per 20-min session. Target recruiting rate was two to three responses per session. Asterisks indicate when each student was trained in the resource room.

BOX 30.3

"Look, Teacher, I'm All Finished!" Teaching Students to Recruit Teacher Attention

Classrooms are extremely busy places, and even the most conscientious teachers can easily overlook students' important academic and social behaviors. Research shows that teachers are more likely to pay attention to a disruptive student than to one who is working quietly and productively (Walker, 1997). It can be hard for teachers to recognize students who need help, especially low-achieving students who are less likely to ask for help (Newman & Golding, 1990).

Although teachers in general education classrooms are expected to adapt instruction to serve students with disabilities, this is not always the case. Most secondary teachers interviewed by Schumm and colleagues (1995) believed that students with disabilities should take responsibility for obtaining the help they need. Thus, knowing how to politely recruit teacher attention and assistance can help students with disabilities function more independently and actively influence the quality of instruction they receive.

Who Should Be Taught to Recruit?

Although most students would probably benefit from learning to recruit teacher praise and feedback, here are some ideal candidates for recruitment training:

Withdrawn Willamena. Willamena seldom asks a teacher anything. Because she is so quiet and well behaved, her teachers sometimes forget she's in the room.

In-a-Hurry Harry. Harry is usually half-done with a task before his teacher finishes explaining it. Racing through his work allows him to be the first to turn it in. But his work is often incomplete and filled with errors, so he doesn't hear much praise from his teacher. Harry would benefit from recruitment training that includes self-checking and self-correction.

Shouting Shelly. Shelly has just finished her work, and she wants her teacher to look at it—right now! But Shelly doesn't raise her hand. She gets her teacher's attention—and disrupts most of her classmates—by shouting across the room. Shelly should be taught appropriate ways to solicit teacher attention.

Pestering Pete. Pete always raises his hand, waits quietly for his teacher to come to his desk, and then politely asks, "Have I done this right?" But he repeats this routine a dozen or more times in a 20-min period, and his teachers find it annoying. Positive teacher attention often turns into reprimands. Recruitment training for Pete will teach him to limit the number of times he cues his teachers for attention.

How to Get Started

1. **Identify target behaviors.** Students should recruit teacher attention for target behaviors that are valued and therefore likely to be reinforced, such as writing neatly and legibly, working accurately, completing assigned work, cleaning up at transitions, and making contributions when working in a cooperative group.
2. **Teach self-assessment.** Students should self-assess their work before recruiting teacher attention (e.g., Sue asks herself, "Is my work complete?"). After the student can reliably distinguish between complete and incomplete work samples, she can learn how to check the accuracy of her work with answer keys or checklists of the steps or components of the academic skill, or how to spot-check two or three items before asking the teacher to look at it.
3. **Teach appropriate recruiting.** Teach students when, how, and how often to recruit and how to respond to the teacher after receiving attention.
   - *When?* Students should signal for teacher attention after they have completed and self-checked a substantial part of their work. Students should also be taught when not to try to get their teacher's attention (e.g., when the teacher is working with another student, talking to another adult, or taking the lunch count).
   - *How?* The traditional hand raise should be part of every student's recruiting repertoire. Other methods of gaining attention should be taught depending on teacher preferences and routines in the general education classroom (e.g., have students signal they need help by standing up a small flag on their desks; expect students to bring their work to the teacher's desk for help and feedback).
   - *How often?* While helping Withdrawn Willamena learn to seek teacher attention, don't turn her into a Pestering Pete. How often a student should recruit varies across teachers and activities (e.g., independent seatwork, cooperative learning groups, whole-class instruction). Direct observation in the classroom is the best way to establish an optimal rate of recruiting; it is also a good idea to ask the regular classroom teacher when, how, and with what frequency she prefers students to ask for help.
   - *What to say?* Students should be taught several statements that are likely to evoke positive feedback from the teacher (e.g., "Please look at my work." "Did I do a good job?" "How am I doing?"). Keep it simple, but teach the student to vary her verbal cues so she will not sound like a parrot.
   - *How to respond?* Students should respond to their teacher's feedback by establishing eye contact, smiling, and saying "Thank you." Polite appreciation is very reinforcing to teachers.
4. **Role-play the complete sequence.** Begin by providing students with a rationale for recruiting (e.g., the teacher will be happy you did a good job, you will get more work done, your grades might improve). Thinking aloud while modeling is a good way to show the recruiting sequence. While performing each step, say, "Okay, I've finished my work. Now I'm going to check it. Did I put my name on my paper? Yes. Did I do all the problems? Yes. Did I follow all the steps? Yes. Okay, my teacher doesn't look busy right now. I'll raise my hand and wait quietly until she comes to my desk." Have another student pretend to be the regular classroom teacher and come over to you when you have your hand up. Say, "Mr. Patterson, please look at my work." The helper says, "Oh, you did a very nice job." Then smile and say, "Thank you, Mr. Patterson." Role-play with praise and offer corrective feedback until the student correctly performs the entire sequence on several consecutive trials.
5. **Prepare students for alternate responses.** Of course, not every recruiting attempt will result in teacher praise; some recruiting responses may even be followed by criticism (e.g., "This is all wrong. Pay better attention the next time."). Use role playing to prepare students for these possibilities and have them practice polite responses (e.g., "Thank you for helping me with this").
6. **Promote generalization to the regular classroom.** The success of any recruitment training effort depends on the student actually using his or her new skill in the regular classroom.

The maintenance condition was continued until the students' mean level of academic engagement was 20% below the mean level during the second treatment phase for five consecutive sessions. Results for three of the study's six participants are shown in Figure 30.11. Although their experimental design did not include an analysis of the yellow paper's effect on maintenance of academic engagement, Cariveau and Kodak (2017) provided a promising demonstration of the potential power of a contrived common stimulus to mediate generalized behavior change.

When choosing a stimulus to be made common to both teaching and social generalization setting(s), practitioners should consider using people. In addition to being a requisite feature of social settings, people are transportable and important sources of reinforcement for many behaviors. A study by Stokes and Baer (1976) is a good example of the potential influence of the evocative effects of the presence of a person in the generalization setting who had a functional role in the learner's acquisition of the target behavior in the instructional setting. Two preschool children with learning disabilities learned word-recognition skills while working as reciprocal peer tutors for one another. However, neither child showed reliable generalization of those new skills in nontraining settings until the peer with whom he had learned the skills was present in the generalization setting.

Some contrived mediating stimuli serve as more than response prompts; they are prosthetic devices that assist the learner in performing the target behavior. Such devices can be especially useful in promoting generalization and maintenance of complex behaviors and extend response chains by simplifying a complex situation. Three common forms are cue cards, visual activity schedules, and self-operated prompting devices.

Cue Cards. Sprague and Horner (1984) gave the students in their study cue cards to aid them in operating a vending machine without another person's assistance. The cue cards, which had food and drink logos on one side and pictures of quarters paired with prices on the other, not only were used during instruction and generalization probes but also were kept by the students at the end of the program. A follow-up 18 months after the study was completed revealed that five of the six students still carried a cue card and were using vending machines independently.

In a study in which middle school students with learning disabilities learned to recruit peer assistance during cooperative learning group activities in the general education classroom, their special education teacher provided each student with a 3- × 5-in. laminated cue card that listed the recruiting steps (Wolford et al., 2001; see Figure 30.12). The students practiced using the card in the special education class where recruiting training took place. They were encouraged to put the cue cards in their language arts notebooks used in the general education classroom and, if necessary, to look at the card during cooperative learning group activities as a reminder of when and how to recruit.

Visual Activity Schedules. Visual activity schedules use icons, photos, illustrations, and real objects to depict a sequence of events the learner will experience or tasks to complete. Some schedules also include performance criteria and a way to check off completed activities and tasks. Figure 30.13 shows two examples of visual activity schedules. Visual activity schedules can facilitate transitions from one activity to the next, provide structure for down time, help the learner understand what activities are associated with different physical spaces, and promote social interactions and communication skills (Banda, Grimmett, & Hart, 2009; Morrison, Sainato, Benchaaban, & Endo, 2002; Pierce, Spriggs, Gast, & Luscre, 2013). A visual schedule can promote independence and self-determination. Individuals who learn to use visual activity schedules no longer require a teacher, parent, or staff member to tell them when to initiate one activity and when to move on to the next. Beyond a simple prompting tool, a visual schedule can promote independence and self-determination.

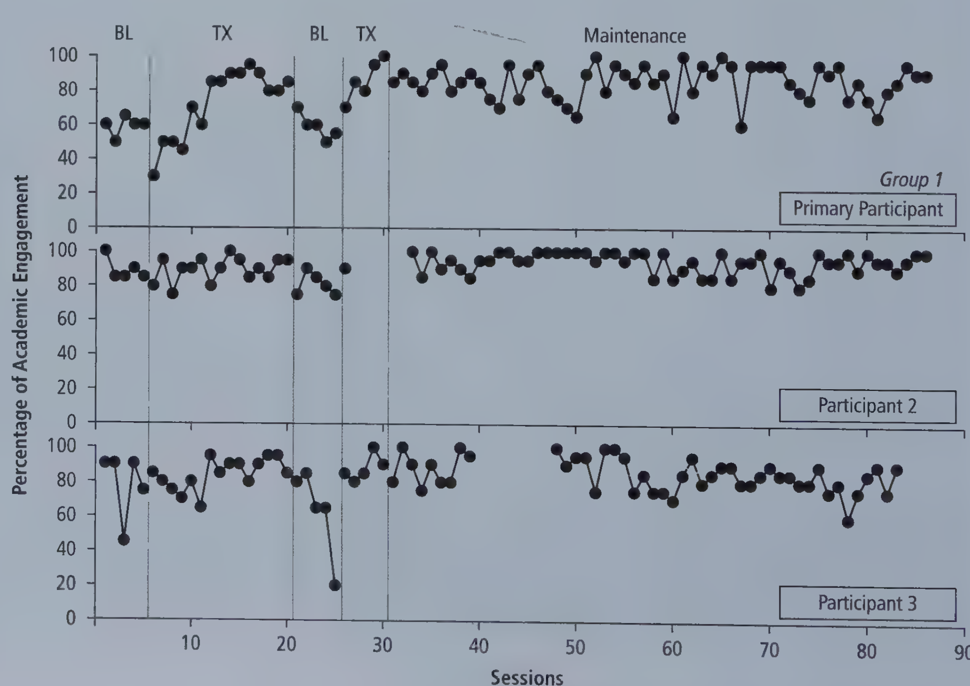

Figure 30.11 Academic engagement by second-grade students during small-group instruction across baseline (BL), treatment (TX), and maintenance conditions. The Primary Participant was the student with the lowest mean level of engagement during baseline. Phase changes were determined by the Primary Participant's data.

From "Programming Randomized Dependent Group Contingency and Common Stimuli to Promote Durable Behavior Change" by T. Cariveau and T. Kodak, 2017, *Journal of Applied Behavior Analysis, 50,* p. 127. Reproduced with permission of John Wiley & Sons, Inc.

Figure 30.12 Middle school students could refer to a laminated card when seeking help from classmates during collaborative learning group activities.

How to Ask for Help

1. Is the teacher talking?
2. Is the student talking to somone else?
3. Get student's attention.
   - say their name quietly
   - say "Excuse me."
   - tap them on shoulder
4. Ask your question clearly.
   - Can you explain what we are supposed to do?
   - How does this look so far?
   - Can you see if I am doing this right?
5. Say "Thank you."

Described in "Teaching Middle School Students with Learning Disabilities to Recruit Peer Assistance During Cooperative Learning Group Activities," by T. Wolford, S. R. Alber, and W. L. Heward, 2001, *Learning Disabilities Research & Practice*, *16*, 161–173.

MacDuff, Krantz, and McClannahan (1993) conducted one of the first behavior analytic experiments evaluating visual activity schedules. They taught four boys with autism, ages 9 to 14, to use visual activity schedules when performing domestic-living skills such as vacuuming and table setting and for leisure activities such as using manipulative toys. The researchers reported that prior to training with photographic activity schedules, the boys required continuous supervision and verbal prompts to complete self-help, housekeeping, and leisure activities. They summarized the results and suggested a possible explanation for the maintenance and generalization as follows.

> When the study ended, all 4 boys were able to display complex home-living and recreational repertoires for an hour, during which time they frequently changed tasks and moved to different areas of their group home without adults' prompts. Photographic activity schedules, . . . became functional discriminative stimuli that promoted sustained engagement after training ceased and fostered generalized responding to new activity sequences and novel leisure materials. (p. 97)

Self-operated Prompting Devices. Numerous studies have shown that learners across a wide range of age and cognitive levels can learn to use mobile audio and video playback devices to independently perform a variety of academic, self-care, domestic, and employment tasks (e.g., Bouck, Satsangi, Muhl, & Bartlett, 2013; Grossi, 1998; Mays & Heflin, 2011; Montgomery, Storey, Post, & Lemley, 2011; Trask-Tyler et al., 1994). The popularity of personal mobile devices such as smartphones and tablets enables a person to listen to or view a series of self-delivered response prompts in a private, normalized manner that does not impose on or bother others (Mechling 2007; Savage, 2014).

Teach Self-management Skills

The most potentially effective approach to mediating generalized behavior changes rests with the one element that is always present in every instructional and generalization setting—the learner herself. Chapter 29 described a variety of self-management tactics that people can use to modify their own behavior. The logic of using self-management to mediate generalized behavior changes goes like this: If the learner can be taught a behavior (not the original target behavior, but another behavior—a controlling response from a self-management perspective) that serves to prompt or reinforce the target behavior in all the relevant settings, at all appropriate times, and in all of its relevant forms, then the generalization of the target behavior is ensured. But as Baer and Fowler (1984) warned:

> Giving a student self-control responses designed to mediate the generalization of some critical behavior changes does not ensure that those mediating responses will indeed be used. They are, after all, just responses: they, too, need generalization and maintenance just as do the behavior changes that they are meant to generalize and maintain. Setting up one behavior to mediate the generalization of another behavior may succeed—but it may also represent a problem in guaranteeing the generalization of two responses, where before we had only the problem of guaranteeing the generalization of one! (p. 149)

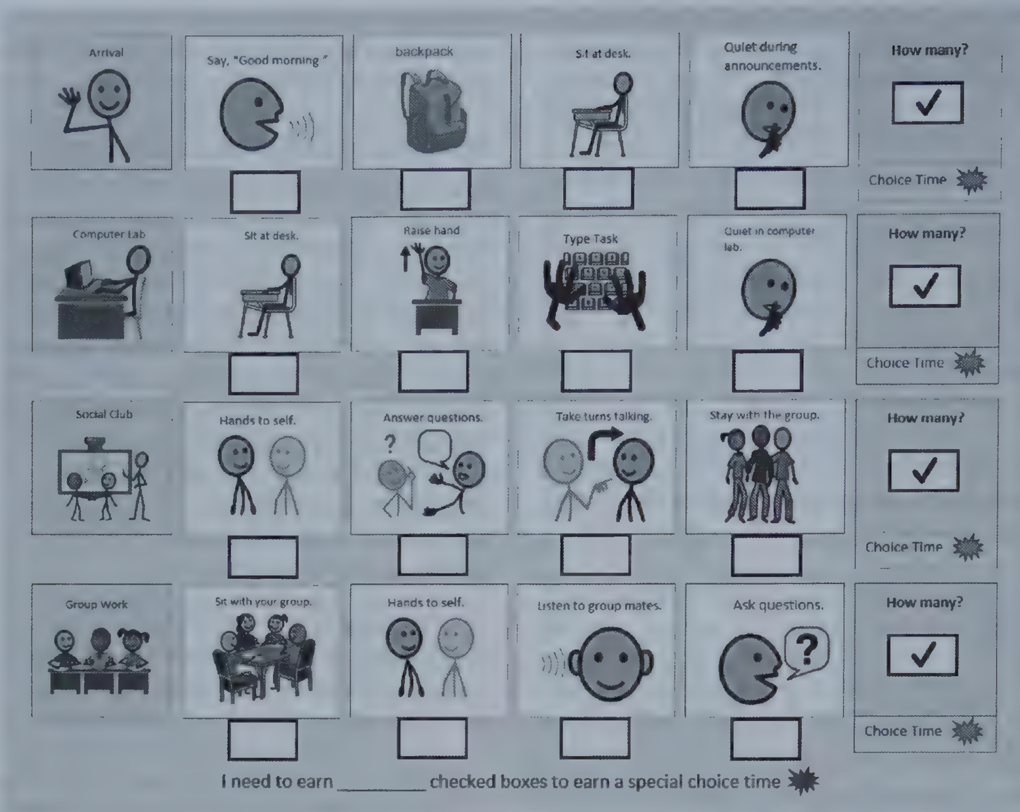
Train to Generalize

> *If generalization is considered as a response itself, then a reinforcement contingency may be placed on it, the same as with any other operant.*
>
> —Stokes and Baer (1977, p. 362)

Training "to generalize" was one of the eight proactive strategies for programming generalized behavior change in Stokes and Baer's (1977) conceptual scheme. The quotation marks around "to generalize" signified that the authors were hypothesizing about the possibilities of treating "to generalize" as an operant response and that they recognized "the preference of behaviorists to consider generalization to be an outcome of behavioral change, rather than as a behavior itself" (p. 363). Although considerable debate surrounds the validity of variable responding being an operant in its own right (e.g., de Souza Barba, 2012; Holth, 2012; Neuringer, 2003, 2004; Peleg, Martin, & Holth, 2017), basic and applied research has demonstrated the pragmatic value of reinforcing varied responding (e.g., Neuringer & Jensen, 2013; Shahan & Chase, 2002). Two tactics that applied behavior analysts have used are reinforcing response variability and instructing the learner to generalize.

Reinforce Response Variability

Response variability can help a person solve problems. A person who can improvise by emitting a variety of responses is more likely to solve problems encountered when a standard response



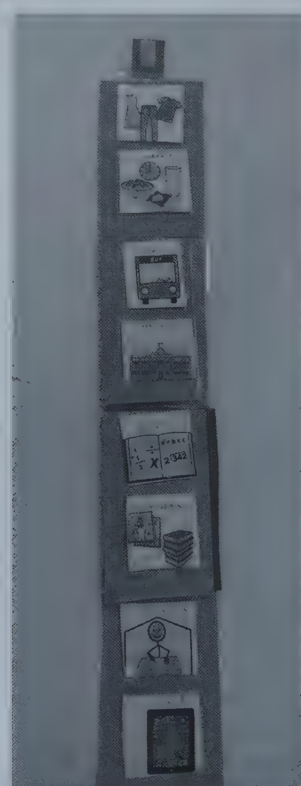


Figure 30.13 The visual activity schedule at the top identifies the sequence of morning activities and criteria for earning the choice of preferred activities during free time. The transportable schedule at the bottom includes changeable icons.

From "Visual Activity Schedules for Students with Autism Spectrum Disorder," by A. Aspen and L. Stack, California Autism Professional Training and Information Network (2017). Used by permission.

form fails to obtain reinforcement (e.g., Arnesen, 2000; Marckel, Neef, & Ferreri, 2006; Miller & Neuringer, 2000; Neuringer, 2004; Shahan & Chase, 2002). Response variability also may result in behavior that is valued because it is novel or creative (e.g., Holman, Goetz, & Baer, 1977; Neuringer, 2003; Pryor, Haag, & O'Reilly, 1969). Response variability may expose a person to sources of reinforcement and contingencies not accessible by more constricted forms of responding. The additional learning that results from contacting those contingencies further expands the person's repertoire.

One direct way to promote desired response generalization is to reinforce response variability when it occurs. The simplest approach entails differential reinforcement of new response forms as Goetz and Baer (1973) did by attending to children when they constructed different blockbuilding forms (see Figure 8.7). Systematic replications of this procedure have ranged from increasing diverse block building by children with autism (Napolitano, Smith, Zarcone, Goodkin, & McAdam, 2010) to varied punching and kicking techniques by martial arts students (Harding, Wacker, Berg, Rick, & Lee, 2004).

The contingency between response variability and reinforcement can be formalized with a lag reinforcement schedule. Reinforcement on a lag schedule is contingent on a response being different in some defined way from the previous response (a Lag 1 schedule) or a specified number of previous responses (Lag 2 or more). Lag reinforcement schedules have produced varied verbal responding by children with disabilities (Contreras & Betz, 2016; Heldt & Schlinger, 2012; see Wiskow & Donaldson's 2016 study discussed in Chapter 13).

Cammilleri and Hanley (2005) used a lag reinforcement contingency to increase varied selections of classroom activities by two typically developing girls, ages 5 and 7, who were selected to participate in the study because they spent the vast majority of their time engaged in activities not systematically designed to result in a particular set of skills within the curriculum. At the beginning of each 60-min session, the children were told they could select any activity and could switch activities at any time. A timer sounded every 5 minutes to prompt activity choices. During baseline, there were no programmed consequences for selecting any of the activities. Intervention consisted of a lag reinforcement schedule in which the first activity selection and each subsequent novel selection were followed by the teacher handing the student a green card that she could exchange later for 2 minutes of teacher attention (resulting in a Lag 12 contingency, which was reset if all 12 activities were selected within a session).

Activity selections during baseline showed little variability, with both girls showing strong preferences for stackable blocks (Figure 30.14 shows results for one of the girls). When the lag contingency was introduced, both girls immediately selected and engaged in more diverse activities. The researchers noted that "an indirect but important outcome of this shift in time allocation was a marked increase in the number of academic units completed" (p. 115).

Instruct the Learner to Generalize

The simplest and least expensive of all tactics for promoting generalized behavior change is to "tell the subject about the possibility of generalization and then ask for it" (Stokes & Baer, 1977, p. 363). For example, Ninness, Fuerst, and Rutherford (1991) explicitly told three middle school students with emotional disturbance to use self-management procedures they had learned in the classroom to self-assess and self-record their behavior while walking from the lunchroom to the classroom. Hughes and colleagues (1995) used a similar procedure to promote generalization: "At the close of each training session, peer teachers reminded participants to self-instruct when they wished to talk to someone" (p. 207). Likewise, at the conclusion of each training session conducted in the special education classroom on how to recruit assistance from peers during cooperative learning groups, Wolford and colleagues (2001) prompted middle school students with learning disabilities to recruit peer assistance at least 2 times but not more than 4 times during each cooperative learning group in the language arts classroom.

To the extent that generalizations occur and are themselves generalized, a person might then become skilled at generalizing newly acquired skills or, in the words of Stokes and Baer (1977), become a "generalized generalizer."

MODIFYING AND TERMINATING SUCCESSFUL INTERVENTIONS

With most successful behavior change programs it is impossible, impractical, or undesirable to continue the intervention indefinitely. Withdrawal of a successful intervention should be carried out in a systematic fashion, guided by the learner's performance of the target behavior in the most important generalization settings. Gradually shifting from the contrived conditions of the intervention to the typical, everyday environment will increase the likelihood that the learner will maintain the new behavior patterns. When deciding how soon and how swiftly to withdraw intervention components, practitioners should consider factors such as the complexity of the intervention, the ease or speed with which behavior changed, and the availability of naturally existing contingencies of reinforcement for the new behavior.

This shift from intervention conditions to the postintervention environment can be made by modifying one or more of the following components, each representing one part of the three-term contingency:

- Antecedents, prompts, or cue-related stimuli
- Task requirements and criteria
- Consequences or reinforcement variables

Although the order in which intervention components are withdrawn may make little or no difference, in most programs it is probably best to make all task-related requirements as similar as possible to those of the postintervention environment before withdrawing significant antecedent or consequence components of the intervention. In this way, the learner will be emitting the target behavior at the same level of performance that will be required after the complete intervention has been withdrawn.

A behavior change program carried out many years ago by a graduate student in one of our classes illustrates how the components of a program can be gradually and systematically withdrawn. A man with developmental disabilities took an inordinate amount of time to get dressed each morning (40 to 70 minutes during baseline), even though he possessed the skills needed to dress himself. Intervention began with a construction paper clock hung by his bed with the hands set to indicate the time by which he had to be fully dressed to receive reinforcement. Although the man could not tell time, he could discriminate whether the position of the hands on the real clock nearby matched those on his paper clock. Two task-related intervention elements were introduced to increase the likelihood of initial success. First, he was

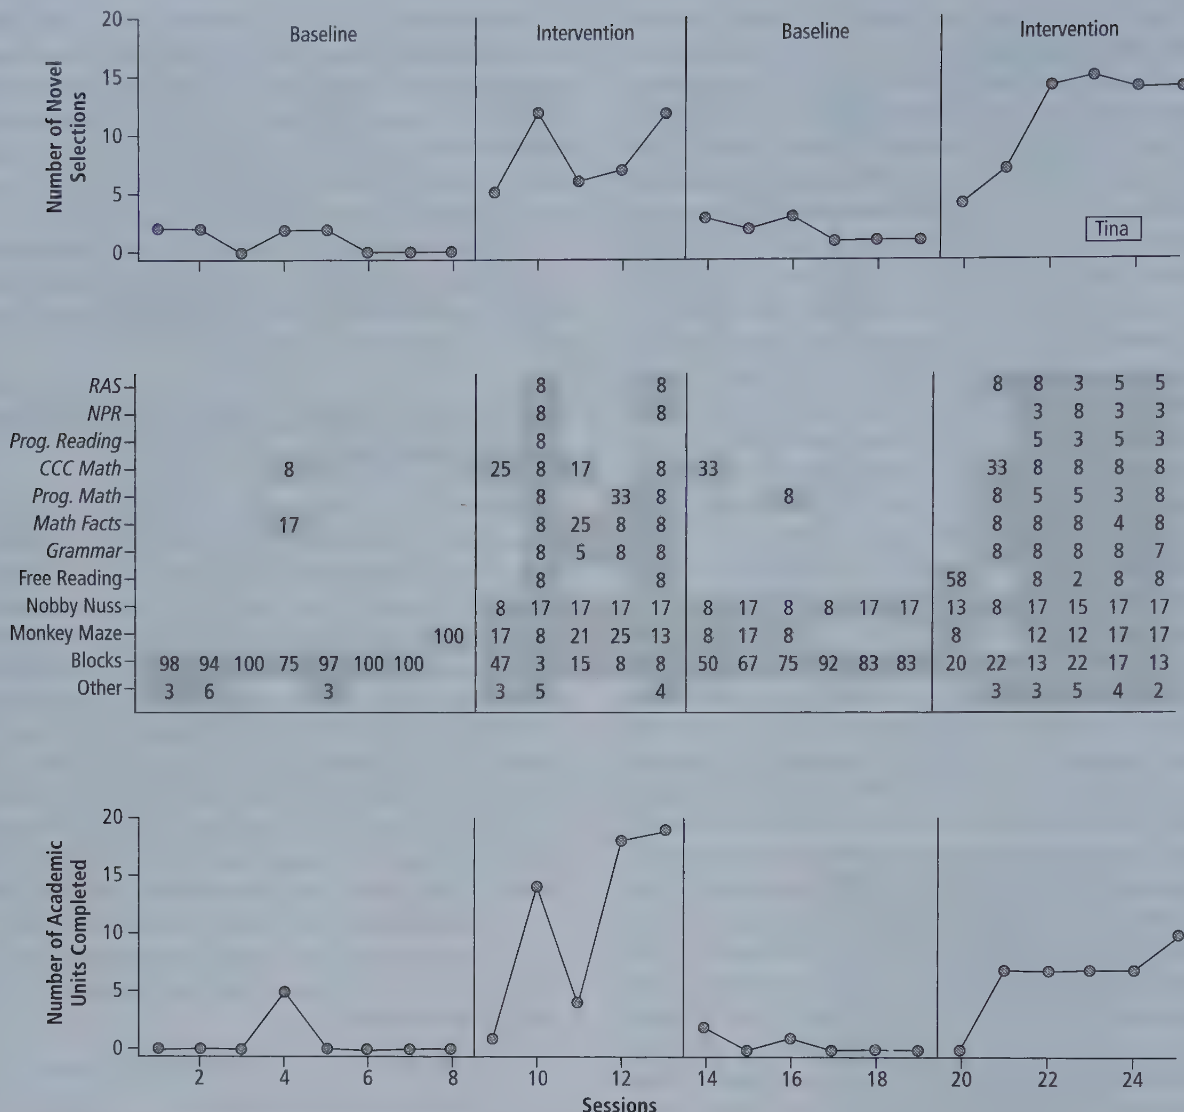

Figure 30.14 Number of novel activity selections (top panel), percentage of intervals of engagement in programmed (italicized) and nonprogrammed activities (middle panel; shaded cells indicate activities for which there was some engagement), and number of academic units completed (bottom panel).

From "Use of a Lag Differential Reinforcement Contingency to Increase Varied Selections of Classroom Activities" by A. P. Cammilleri and G. P. Hanley, 2005, *Journal of Applied Behavior Analysis, 38,* p. 114. Reproduced with permission of John Wiley & Sons, Inc.

given fewer and easier clothes to put on each morning (e.g., no belt, slip-on loafers instead of shoes with laces). Second, based on his baseline performance, he was initially given 30 minutes to dress himself, even though the objective of the program was for him to be completely dressed within 10 minutes. An edible reinforcer paired with verbal praise was used first on a continuous schedule of reinforcement. Figure 30.15 shows how each aspect of the intervention (antecedent, behavior, and consequence) was modified and eventually withdrawn completely, so that by the program's end the man was dressing himself completely within 10 minutes without the aid of extra clocks or charts or contrived reinforcement other than a naturally existing schedule of intermittent praise from staff members.

Rusch and Kazdin (1981) described a method for systematically withdrawing intervention components while simultaneously assessing response maintenance that they called "partial-sequential withdrawal." Martella, Leonard, Marchand-Martella, and Agran (1993) used a partial-sequential withdrawal of various components of a self-monitoring intervention they had implemented to help Brad, a 12-year-old student with mild cognitive disabilities, reduce the number of negative statements (e.g., "I hate this @#!%ing calculator," "Math is crappy") he made during classroom activities. The self-management intervention consisted of Brad (a) self-recording negative statements on a form during two class periods, (b) charting the number on a graph, (c) receiving his choice from a menu of "small" reinforcers (items costing 25 cents or less), and (d) being allowed to choose a "large" reinforcer (more than 25 cents) when his self-recorded data were in agreement with the trainer and at or below a gradually reducing criterion level for four consecutive sessions. After the rate of Brad's negative statements was reduced, the researchers began

Antecedents (cues, prompts)	Behavior (task criteria/ modifications)	Consequences (reinforcers, punishers)
A: Mock clock showing when must be dressed	A: Fewer clothes	A: Edible reinforcer
B: No clock	B: Full set of clothes	B: Token reinforcer
	C: Time gradually reduced	C: Chart (self-record)
	D: Criterion time limit	D: Praise on intermittent schedule
	E: Variety of clothes	

Phase	Antecedents	Behavior	Consequences
1	A	A	A
2	A	A	B
3	A	B	B
4	A	B/C	C
5	A	B/D	C
6	B	B/D	C
7	B	D/E	C
8	B	D/E	D

Figure 30.15 Modification and withdrawal of intervention components to facilitate maintenance and generalization of independent morning dressing by an adult with developmental disabilities.

a four-phase partial-sequential withdrawal of the intervention. In the first phase, charting and earning of "large" reinforcers were withdrawn; in the second phase, Brad was required to have zero negative statements in both periods to receive a daily "small" reinforcer; in the third phase, Brad used the same self-monitoring form for both class periods instead of one form for each period, as before, and the small reinforcer was no longer provided; and in the fourth phase (the follow-up condition), all components of the intervention were withdrawn except for the self-monitoring form without a criterion number highlighted. Brad's negative statements remained low throughout the gradual and partial withdrawal of the intervention (see Figure 30.16).

Another approach to terminating an effective intervention is gradually thinning the schedule of days or sessions in which the full intervention operates. For example, after Falkenberg and Barbetta (2013) determined that homework completion and accuracy by four elementary students had increased and remained high for several weeks as a function of an intervention consisting of self-monitoring and a brief daily conference with their special education teacher to review their self-monitoring sheets, the researchers moved to Fading I and II conditions. In Fading I, the students continued to self-monitor their homework performance daily but met with their teacher only twice per week; in Fading II, self-monitoring continued but conference with the teacher occurred just once per week. Students' homework completion accuracy remained high throughout the two fading conditions and a final maintenance phase in which the students were no longer prompted to self-monitor and no teacher conferences took place.

A word of caution is in order regarding the termination of successful behavior change programs. Achieving socially significant improvements in behavior is a defining purpose of applied behavior analysis. Additionally, those improved behaviors should be maintained and should show generalization to other relevant settings and behaviors. In most instances, achieving optimal generalization of the behavior change will require most, if not all, of the intervention components to be withdrawn. However, practitioners, parents, and others responsible for helping children learn important behaviors are sometimes more concerned with whether and with how a potentially effective intervention will eventually be withdrawn than they are with whether it will produce the needed behavior change. Considering how a proposed intervention will lend itself to eventual withdrawal or blending into the natural environment is important and consistent with everything recommended throughout this book. And clearly, when the choice is between two or more interventions of potentially equal effectiveness, the intervention that is most similar to the natural environment and the easiest to withdraw and terminate should be given first priority. However, an important behavior change should not be forsaken because complete withdrawal of the intervention required to achieve it is considered unlikely. Some level of intervention may always be required to maintain certain behaviors.

GUIDING PRINCIPLES FOR PROMOTING GENERALIZED OUTCOMES

Regardless of the specific tactics selected and applied, we believe that practitioners' efforts to promote generalized behavior change will be enhanced by adherence to five guiding principles:

1. Minimize the need for generalization as much as possible.
2. Conduct generalization probes before, during, and after instruction.
3. Involve significant others whenever possible.
4. Promote generalization with the least intrusive, least costly tactics possible.
5. Contrive intervention tactics as needed to achieve important generalized outcomes.

Minimize the Need for Generalization

Practitioners should reduce the need for generalization to untaught skills, settings, and situations as much as possible. Doing so requires thoughtful, systematic assessment of what behavior changes are most important. Practitioners should

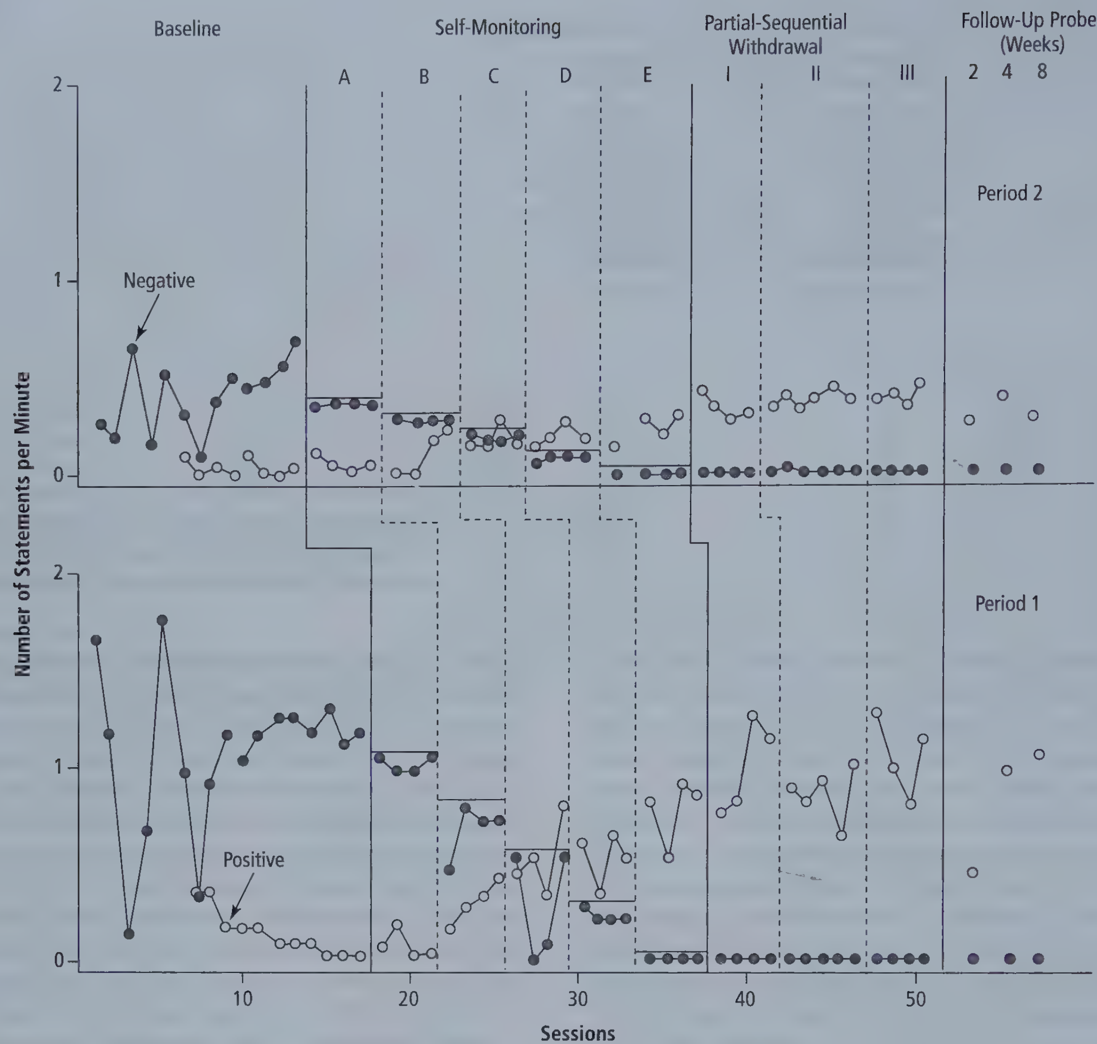

Figure 30.16 Number of negative (solid data points) and positive (open data points) statements in two class periods by a 12-year-old boy with disabilities during baseline, self-monitoring, and partial-sequential withdrawal conditions. Horizontal lines during the self-monitoring condition show changing criteria for teacher-delivered reinforcement.

"Self-Monitoring Negative Statements" by R. Martella, I. J. Leonard, N. E. Marchand-Martella, and M. Agran, 1993, *Journal of Behavioral Education, 3,* p. 84. Copyright 1993 by Human Sciences Press. Reprinted by permission.

prioritize the knowledge and skills that will most often be required of the learner and the settings and situations in which the learner will most often benefit from using those skills. In addition to the environment(s) in which the learner is currently functioning, practitioners should consider the environments in which the learner will function in the immediate future and later in life.

The most critical behavior changes should not be relegated to the not-for-certain technology of generalization. The most important skill-setting-stimulus combinations should always be taught directly and, when possible, taught first. For example, a training program to teach a young adult with disabilities to ride the public bus system should use the bus routes the person will take most often (e.g., to and from her home, school, job site, and community recreation center) as teaching examples. Instead of providing direct instruction on routes to destinations the learner may visit only occasionally after training, use those routes as generalization probes. Achieving a high level of response maintenance on the trained routes will still be a challenge.

Probe for Generalization Before, During, and After Instruction

Generalization probes should be conducted prior to, during, and after instruction.

Probe Before Instruction

Probes conducted prior to instruction may reveal that the learner already performs some or all of the needed behaviors in the generalization setting, thereby reducing the scope of the teaching task. It is a mistake to assume that because a learner does not perform a particular behavior in the instructional setting, she does not or cannot do it in the generalization setting(s). Preinstruction probe data are the only objective basis for knowing that the learner's performance of the target behavior *after instruction* is, in fact, a generalized outcome.

Additionally, probes before instruction enable observation of the contingencies that operate in the generalization setting.

Knowledge of such information may contribute to a more effective treatment or instruction.

Probe During Instruction

Probes during instruction reveal if and when generalization has occurred and if and when instruction can be terminated or shifted in focus from acquisition to maintenance. A teacher who finds that a student can solve untaught examples of a particular type of algebraic equation after receiving instruction on just a few examples, and shifts instruction to the next type of equation in the curriculum, will cover more of the algebra program effectively than will a teacher who continues to present additional examples.

Probes during instruction also show whether generalization is not occurring, thereby indicating that a change in instructional strategies is needed. When Sprague and Horner (1984) observed that one student's poor performance on a generalization probe was caused by a ritualistic pattern of inserting coins, they incorporated repeated practice on the coin insertion step during a training session and the student's performance on the generalization task improved greatly.

In a study on teaching children with autism to respond with empathy to others, Sivaraman (2017) randomly interspersed generalization probes during all treatment sessions. Probes were presented in the same manner as during baseline. The nontraining discriminative stimuli presented during each probe trial belonged to the same antecedent emotion category (frustration, sadness, or happiness) that was being trained. To assess the extent to which tackling by high school football players generalized from practice with a dummy bag at walking speed to tackling a live ball carrier, Harrison and Pyles (2013) conducted probe sessions of four-tackle generalization probes at each stage of a shaping program (see Figure 22.4).

Generalization probes can often be made more efficient by contriving opportunities for the learner to use her new knowledge or skill. For example, instead of waiting for (and perhaps missing) naturally occurring opportunities for the learner to use her new conversational skills in the generalization environment, a practitioner could enlist the assistance of a "confederate" peer to approach the learner. Ninness et al. (1991) used contrived generalization probes in which students were provoked or distracted to test the extent to which they used a set of self-management skills.

Contrived generalization probes can also be used as the primary measure of acquisition and generalization. For example, Miltenberger and colleagues (2005) contrived opportunities to measure and teach children's use of gun safety skills by placing a gun in home and school locations where the children would find it. If a child did not execute the target safety skills when finding a gun (i.e., do not touch it, get away from the gun, and tell an adult), the trainer entered the room and conducted an *in situ* training session, asking the child what he should have done and rehearsing the entire sequence 5 times.

Probe After Instruction

Probes after instruction has ended reveal the extent of response maintenance. The question of how long probes should be conducted after instruction has ended should be answered by factors such as the severity of the target behavior, the importance of the behavior change to the person's quality of life, the strength and consistency of the response maintenance obtained by probes to date, and so forth. The need for long-term assessment of maintenance is especially critical for severe behavior problems. In some cases, maintenance probes over many months and several years may be indicated (e.g., Derby et al., 1997; Wagman, Miltenberger, & Woods, 1995). Reid, Parsons, and Jensen (2017) reported that after intensive staff training at a center for adolescents and adults with severe disabilities brought about desired performance (increased participant involvement in functional tasks), supervisors observed staff and provided performance feedback approximately once per week for 12 weeks and thereafter monthly. This program of ongoing monitoring and feedback maintained high levels of staff performance over follow-up observations spanning 30 years.

If conducting systematic generalization and maintenance probes seems too difficult or too contrived, the practitioner should consider the relative importance of the target behavior to the student or client. If a behavior is important to target for intervention, then assessing the generalized outcomes of that intervention is worth whatever effort that assessment requires.

Involve Significant Others

> *All persons are potential teachers of all sorts of behavior changes. Just because you are designated as "teacher" or "behavior analyst" does not mean that you have an exclusive franchise on the ability to make deliberate behavior changes. In fact, there is no possibility of such a franchise. Everyone in contact contributes to everyone else's behavior, both to its changes and its maintenance.*
>
> —Donald M. Baer (1999, p. 12)

Teaching for generalized outcomes is a big job, and practitioners should try to get as much help as they can. People are almost always around where and when important behaviors need to be prompted and reinforced; and when social behaviors are targeted, people are there by definition.

In virtually every behavior change program, people other than the participant and the behavior analyst are involved, and their cooperation is crucial to the success of the program. Foxx (1996) stated that in programming successful behavior change interventions, "10% is knowing what to do; 90% is getting people to do it. . . . Many programs are unsuccessful because these percentages have been reversed" (p. 230). Although Foxx was referring to the challenge and importance of getting staff to implement programs with the consistency and fidelity needed for success, the same holds for the involvement of significant others.

Baer (1999) suggested identifying others who will or may be involved in a behavior change program as active supporters or tolerators. An active supporter is someone naturally present in the generalization setting who helps promote the generalization and maintenance of the target behavior by doing specific things. Active supporters help facilitate the desired generalized outcomes by arranging opportunities for the learner to use or practice the new skill, giving cues and response prompts for the behavior, and providing reinforcement for performance of the target behavior.

Active supporters for a behavior change program to teach independent eating to a child with severe disabilities might include one or two key people in the school's cafeteria, a volunteer or aide who works regularly with the child, the child's parents, and an older sibling. These people are vital parts of the teaching team. If optimal generalization is to occur, the active supporters must see to it that the learner has many opportunities to use the new skill in the generalization environments they share, and the natural reinforcers they control in those environments (e.g., praise, touch, smiles, companionship) must be used as consequences for the target behavior. It is not necessary, and probably not desirable, to limit an active supporters list to school staff, family members, and peers. They may not be regularly available in all the environments and situations in which generalization is desired.

A tolerator is someone in the generalization setting who agrees not to behave in ways that would impede the generalization plan. Tolerators should be informed that the learner will be using a new skill in the generalization environment and asked to be patient. In an independent eating program, a list of tolerators would likely include some members of the child's family, school cafeteria staff, and peers. Beyond the home and school environments, the behavior analyst should consider the possible role of the general public with whom the child may find herself sharing a table or dining area in a public restaurant. The learner's initial sloppiness and slowness (she may always be sloppier and slower than most people) as she makes the first attempts beyond the familiar contingencies of home and school might result in various responses from strangers that could punish the new eating skills. Being stared at, laughed at, talked about, told to hurry up, or even offered assistance could reduce the possibility of generalization. Certainly, the behavior analyst can inform various school staff and family members of the ongoing eating program and request that they not interfere with the child's attempts to eat independently. But the public at large is another issue. It is impossible to inform everyone of the program. However, by considering the types of intolerant behaviors that the learner may encounter in the generalization setting, the teaching program can be constructed to include practice under such intolerant conditions. Instructional trials might be contrived to reinforce the learner for ignoring rude remarks and continuing to eat independently.

Use the Least Intrusive, Least Costly Tactics Possible

Behavior analysts should use less intrusive and less costly tactics to promote generalization before using more intrusive and more costly tactics. As noted previously, simply reminding students to use their new skills in the generalization setting is the easiest and least expensive of all methods that might promote generalization. Although practitioners should never assume that telling the learner to generalize will produce the desired outcomes, neither should they fail to include such a simple and cost-free tactic. Similarly, incorporating some of the most relevant features of the generalization setting into the instructional setting (i.e., programming common stimuli) often helps produce the needed generalization and is less costly than conducting instruction in the natural setting (e.g., Neef, Lensbower et al., 1990; van den Pol et al., 1981).

Not only is using less costly tactics good conservation of the limited resources available for teaching, but also less intrusive interventions with fewer moving parts are easier to withdraw. Systematic generalization probes will determine whether generalization has occurred and whether more elaborate and intrusive intervention and supports are needed.

Contrive Intervention Tactics as Needed to Achieve Important Generalized Outcomes

A practitioner should not be so concerned about intrusiveness that she fails to implement a potentially effective intervention or procedures that will achieve important outcomes for the learner. Therefore, if necessary, practitioners should disregard the previous guideline and contrive as many instruction and generalization tactics as necessary to enable the learner to generalize and maintain critical knowledge and skills.

Rather than lament the lack of generalization or blame the learner for his inability to show generalized behavior changes, the behavior analyst should work to arrange whatever socially valid contingencies may be needed to extend and maintain the target behavior.

Some Final Words of Wisdom from Don Baer

The most difficult and important challenge facing behavioral practitioners is helping learners achieve generalized change in socially significant behaviors. A behavior change—no matter how important initially—is of little value to the learner if it does not last over time, is not emitted in appropriate settings and situations, or occurs in restricted form when varied topographies are desired.

Research during the past 40 years has developed and advanced the knowledge base of what Stokes and Baer (1977) described as an "implicit technology of generalization" into an increasingly explicit and effective set of strategies and tactics for promoting generalized behavior change. Knowledge of these methods, combined with knowledge of the basic principles and behavior change tactics described throughout this book, provides behavior analysts with a powerful approach for helping people enjoy healthy, happy, and productive lives.

We end this chapter with a dually wise observation by Don Baer (1999), in which he pointed out a fundamental truth about the relation between a person's experience (in this case, the nature of a lesson) and what is learned or not learned from that experience. Like Skinner before him, Baer wisely reminded us not to blame the learner for not behaving as we think he should.

> Learning one aspect of anything never means that you will automatically know the rest of it. Doing something skillfully now never means that you will always do it well. Resisting one temptation consistently never means that you now have character, strength, and discipline. Thus, it is not the learner who is dull, learning disabled, or immature, because all learners are alike in this regard: *no one learns a generalized lesson unless a generalized lesson is taught.* (p. 1) [emphasis in original]

SUMMARY

Generalized Behavior Change: Definitions and Key Concepts

1. Generalized behavior change has taken place if trained behavior occurs at other times or in other places without having to be retrained completely in those times or places, or if functionally related behaviors occur that were not taught directly.
2. Response maintenance refers to the extent to which a learner continues to perform a behavior after a portion or all of the intervention responsible for the behavior's initial appearance in the learner's repertoire has been terminated.
3. Setting/situation generalization refers to the extent to which a learner emits the target behavior in settings or situations that are different from the instructional setting.
4. The instructional setting is the environment where instruction occurs and encompasses all aspects of the environment, planned or unplanned, that may influence the learner's acquisition and generalization of the target behavior.
5. A generalization setting is any place or stimulus situation that differs from the instructional setting in some meaningful way and in which performance of the target behavior is desired.
6. Response generalization refers to the extent to which a learner emits untrained responses that are functionally equivalent to the trained response.
7. Some interventions yield significant and widespread generalized effects across time, settings, and other behaviors; others produce circumscribed changes in behavior with limited endurance and spread.
8. Undesirable setting/situation generalization takes two common forms: overgeneralization, in which the behavior has come under control of a stimulus class that is too broad, and faulty stimulus control, in which the behavior comes under the control of an irrelevant antecedent stimulus.
9. Undesired response generalization occurs when any of a learner's untrained but functionally equivalent responses produce undesirable outcomes.
10. Other types of generalized outcomes (e.g., stimulus equivalence, contingency adduction, and generalization across subjects) do not fit easily into categories of response maintenance, setting/situation generalization, and response generalization.
11. The generalization map is a conceptual framework for combining and categorizing the various types of generalized behavior change.

Planning for Generalized Behavior Change

12. The first step in promoting generalized behavior changes is to select target behaviors that will meet naturally existing contingencies of reinforcement.
13. A naturally existing contingency is any contingency of reinforcement (or punishment) that operates independent of the behavior analyst's or practitioner's efforts, including socially mediated contingencies contrived by other people and already in effect in the relevant setting.
14. A contrived contingency is any contingency of reinforcement (or punishment) designed and implemented by a behavior analyst to achieve the acquisition, maintenance, and/or generalization of a targeted behavior change.
15. Planning for generalization includes identifying all the desired behavior changes and all the environments in which the learner should emit the target behavior(s) after direct training has ceased.
16. Benefits of developing the planning lists include a better understanding of the scope of the teaching task and an opportunity to prioritize the most important behavior changes and settings for direct instruction.

Strategies and Tactics for Promoting Generalized Behavior Change

17. Researchers have developed and advanced what Stokes and Baer (1977) called an "implicit technology of generalization" into an increasingly explicit and effective set of methods for promoting generalized behavior change.
18. The strategy of teaching enough examples requires teaching a subset of all of the possible stimulus and response examples and then assessing the learner's performance on untrained examples.
19. A generalization probe is any measurement of a learner's performance of a target behavior in a setting and/or stimulus situation in which direct training has not been provided.
20. Teaching enough stimulus examples involves teaching the learner to respond correctly to more than one example of an antecedent stimulus and probing for generalization to untaught stimulus examples.
21. As a general rule, the more examples the practitioner uses during instruction, the more likely the learner will be to respond correctly to untrained examples or situations.
22. Having the learner practice a variety of response topographies helps ensure the acquisition of desired response forms and promotes response generalization. Often called multiple-exemplar training, this tactic typically incorporates numerous stimulus examples and response variations.
23. General case analysis is a systematic method for selecting teaching examples that represent the full range of stimulus variations and response requirements in the generalization setting.

24. Negative, or "don't do it," teaching examples help learners identify stimulus situations in which the target behavior should not be performed.

25. Minimum difference negative teaching examples, which share many characteristics with positive teaching examples, help eliminate "generalization errors" due to overgeneralization and faulty stimulus control.

26. The greater the similarity between the instructional setting and the generalization setting, the more likely the target behavior will be emitted in the generalization setting.

27. Programming common stimuli means including in the instructional setting stimulus features typically found in the generalization setting. Practitioners can identify possible stimuli to make common by direct observation in the generalization setting and by asking people who are familiar with the generalization setting.

28. Teaching loosely—randomly varying noncritical aspects of the instructional setting within and across teaching sessions—(a) reduces the likelihood that a single or small group of noncritical stimuli will acquire exclusive control over the target behavior and (b) makes it less likely that the learner's performance will be impeded or "thrown off" by the presence of a "strange" stimulus in the generalization setting.

29. A newly learned behavior may fail to contact an existing contingency of reinforcement because it has not been taught well enough. The solution for this kind of generalization problem is to teach the learner to emit the target behavior at the rate, accuracy, topography, latency, duration, and/or magnitude required by the naturally occurring contingencies of reinforcement.

30. The use of intermittent schedules of reinforcement and delayed rewards can create indiscriminable contingencies, which promote generalized responding by making it difficult for the learner to discriminate whether the next response will produce reinforcement.

31. Behavior traps are powerful contingencies of reinforcement with four defining features: (a) They are "baited" with virtually irresistible reinforcers; (b) only a low-effort response already in the student's repertoire is needed to enter the trap; (c) interrelated contingencies of reinforcement inside the trap motivate the student to acquire, extend, and maintain targeted skills; and (d) they can remain effective for a long time.

32. One way to wake up an existing but inoperative contingency of reinforcement is to ask key people in the generalization setting to attend to and praise the learner's performance of the target behavior.

33. Another tactic for waking up a natural contingency of reinforcement is to teach the learner how to recruit reinforcement in the generalization setting.

34. One tactic for mediating generalization is to bring the target behavior under the control of a contrived stimulus in the instructional setting that will reliably prompt or aid the learner's performance of the target behavior in the generalization setting.

35. Teaching a learner self-management skills with which he can prompt and maintain targeted behavior changes in all relevant settings at all times is the most potentially effective approach to mediating generalized behavior changes.

36. The strategy of training to generalize is predicated on treating "to generalize" as an operant response class that, like any other operant, is selected and maintained by contingencies of reinforcement.

37. One tactic for promoting response generalization is to reinforce response variability. On a lag reinforcement schedule, reinforcement is contingent on a response being different in some defined way from the previous response (a Lag 1 schedule) or a specified number of previous responses (Lag 2 or more).

38. The simplest and least expensive tactic for promoting generalized behavior change is to tell the learner about the usefulness of generalization and then instruct him to do so.

Modifying and Terminating Successful Interventions

39. With most successful behavior change programs it is impossible, impractical, or undesirable to continue the intervention indefinitely.

40. The shift from formal intervention procedures to a normal everyday environment can be accomplished by gradually withdrawing elements constituting the three components of the training program: (a) antecedents, prompts, or cue-related stimuli; (b) task modifications and criteria; and (c) consequences or reinforcement variables.

41. An important behavior change should not go unmade because complete withdrawal of the intervention required to achieve it may never be possible. Some level of intervention may always be required to maintain certain behaviors, in which case attempts must be made to continue necessary programming.

Guiding Principles for Promoting Generalized Outcomes

42. Efforts to promote generalized behavior change will be enhanced by adhering to five guiding principles:
    - Minimize the need for generalization as much as possible.
    - Conduct generalization probes before, during, and after instruction.
    - Involve significant others whenever possible.
    - Promote generalized behavior change with the least intrusive, least costly tactics possible.
    - Contrive intervention tactics as needed to achieve important generalized outcomes.

KEY TERMS

behavior trap
contrived contingency
contrived mediating stimulus
general case analysis
generalization
generalization across subjects
generalization probe

MULTIPLE-CHOICE QUESTIONS

1. This is the extent to which a learner emits the target behavior in a setting or stimulus situation that is different from the instructional setting.
   a. Setting/situation maintenance
   b. Response generalization
   c. Setting/situation generalization
   d. Response maintenance
   Hint: (See "Generalized Behavior Change: Definitions and Key Concepts")

2. This is the extent to which a learner emits untrained responses that are functionally equivalent to the trained target behavior
   a. Setting/situation maintenance
   b. Response generalization
   c. Setting/situation generalization
   d. Response maintenance
   Hint: (See "Generalized Behavior Change: Definitions and Key Concepts")

3. A learner's untrained but functionally equivalent responses result in poor performance. This would be an example of:
   a. Overgeneralization
   b. Faulty stimulus control
   c. Undesirable outcome of setting/situation generalization
   d. Undesirable outcome of response generalization
   Hint: (See "Generalized Behavior Change: Definitions and Key Concepts")

4. When a target behavior comes under the restricted control of an irrelevant antecedent stimulus, it is an example of:
   a. Overgeneralization
   b. Faulty stimulus control
   c. Undesirable outcome of response maintenance
   d. Undesirable outcome of response generalization
   Hint: (See "Generalized Behavior Change: Definitions and Key Concepts")

5. A contingency that operates without social mediation is referred to as:
   a. Natural contingency
   b. Contrived contingency
   c. Unplanned contingency
   d. Generalized contingency
   Hint: (See "Planning for Generalized Behavior Change")

6. Choosing only those behaviors to change that will produce reinforcers in the post-intervention environment is referred to as:
   a. Teaching loosely
   b. Contrived contingency planning
   c. Programming common stimuli
   d. Relevance-of-behavior rule
   Hint: (See "Planning for Generalized Behavior Change")

7. The actual number of examples needed to be taught when teaching sufficient stimulus examples to a learner will depend on:
   a. The learner's opportunities to emit the target behavior under various conditions
   b. Naturally existing contingencies of reinforcement
   c. The learner's history of reinforcement for generalized responding
   d. All of these
   Hint: (See "Strategies and Tactics for Promoting Generalized Behavior Change")

8. When using multiple exemplar training,
   a. Only stimulus variations should be used
   b. Only response variations should be used
   c. Both stimulus and response variations should be used
   d. Neither stimulus nor response variations should be used
   Hint: (See "Strategies and Tactics for Promoting Generalized Behavior Change")

9. Including typical features of the generalization setting into the instructional setting is referred to as:
   a. Teaching loosely
   b. Teaching negative examples
   c. General case analysis
   d. Programming common stimuli
   Hint: (See "Strategies and Tactics for Promoting Generalized Behavior Change")

10. Shifting from intervention to post-intervention conditions can be accomplished by modifying:

a. Antecedents, prompts, or cue-related stimuli

b. Task requirements and criteria

c. Consequences or reinforcement variables

d. All of these

Hint: (See "Modifying and Terminating Successful Interventions")

11. A guiding principle for promoting generalized behavior change includes:

a. Involving significant others whenever possible

b. Promoting generalization with the least intrusive, least costly tactics possible

c. Contriving intervention tactics as needed to achieve important generalized outcomes

d. All of these

Hint: (See "Guiding Principles for Promoting Generalized Outcomes")

ESSAY-TYPE QUESTIONS

1. Name and discuss the three major types of generalized behavior change.

Hint: (See "Generalized Behavior Change: Definitions and Key Concepts")

2. Discuss overgeneralization and faulty stimulus control, and how each can be detrimental to the generalized behavior change for a learner.

Hint: (See "Generalized Behavior Change Is not always desirable")

3. Explain the most important criterion that the text discusses when planning for generalized behavior change.

Hint: (See "Planning for Generalized Behavior Change")

4. There are a number of strategies and tactics that can be utilized to promote generalized behavior change. What are three of these strategies, and how does each one aim to promote generalized behavior change for the learner?

Hint: (See "Strategies and Tactics for Prompting Generalized Behavior Change")

5. When deciding how soon to withdraw an intervention or components of the intervention, what should be considered?

Hint: (See "Modifying and Terminating Successful Interventions")

6. What are the five guiding principles for promoting generalized behavior change?

Hint: (See "Guiding Principles for Promoting Generalized Outcomes")

NOTES

1. Wacker and colleagues (2017) proposed another conception of maintenance: the persistence of treatment effects when treatment is challenged.
2. Because the majority of the examples in this chapter are school based, we use the language of education. To help generalize the examples beyond schooling, read *instruction* as a synonym for *treatment, intervention,* or *therapy; instructional setting* as a synonym for *clinical setting* or *therapy setting;* and *teacher* as a synonym for *practitioner, clinician,* or *therapist.*
3. The unintended maintenance of problem behavior that may result from the manner in which interventions are withdrawn is an undesirable outcome (Ringdahl & St. Peter, 2017). See discussion of resurgence in Chapter 24.
4. Examples of faulty stimulus control caused by flaws in the design of instructional materials, and suggestions for detecting and correcting those flaws, can be found in J. S. Vargas (1984).
5. Teaching a new behavior without developing and implementing a plan to facilitate its maintenance and generalization is so common that Stokes and Baer (1977) called it the "train and hope" approach to generalization.
6. Other terms commonly used for this strategy for promoting generalized behavior change are *training sufficient exemplars, training diversely,* and *multiple-exemplar training.*
7. LaFrance, Tarbox, and Holth (2019) proposed the term *mixed operant instruction* for teaching that features a rapid rotation between consecutive trials that target different operants. Teaching the same target (e.g., water) across verbal operants (e.g., mand, tact, intraverbal) can promote functional interdependence between verbal operants and between speaker and listener repertoires (Fiorile & Greer, 2007; Greer, Stolfi, Chavez-Brown, & Rivera-Valdes, 2005; Nuzzolo-Gomez & Greer, 2004; Olaff, Ona, & Holth, 2017).
8. Holth (2017) identifies two situations in which multiple-exemplar training is ineffective: when (a) there are no physical dimensions along which generalized responding can emerge, or (b) the relation between an antecedent stimulus and an effective response is complex.
9. For a thorough and sophisticated treatment of the selection and sequencing of teaching examples for optimally effective and efficient curriculum design, see Engelmann and Carnine's (1982) *Theory of Instruction: Principles and Applications.* Critchfield and Twyman (2014) and Twyman, Layng, Stikeleather, and Hobbins (2004) also discuss curriculum design from the standpoint of maximizing learning outcomes.
10. Teaching examples used to help students discriminate when not to respond (i.e., S^{Δ}s) are sometimes called *negative examples* and contrasted with positive examples (i.e., S^{D}s). However, in our work in teaching this concept, practitioners have told us that the term *negative teaching example* suggests that the teacher is modeling or showing the learner *how* not to perform the target behavior. Instruction on the desired topography for some behaviors may be aided by providing students with models on how not to perform certain behavior (i.e., negative examples), but the function of "don't do it" examples is to help the learner discriminate antecedent conditions that signal an inappropriate occasion for responding.
11. Coach Hill's effort to simulate the din opposing teams must deal with at "The Shoe" may have helped; his team scored twice. A bit of programming for generalization, however, could not overcome other variables, most notably the home team's overwhelming prowess. Final score: Buckeyes 43, Bulldogs 10.

PART 13

Ethics

In Chapter 31, Tom Freeman, Linda LeBlanc, and Jose Martinez-Diaz help behavior analysts address three fundamental questions concerning ethical practice: What is the right thing to do? What is worth doing? and What does it mean to be a good behavior analyst? The authors define ethics; outline standards of professional practice and a code of conduct for behavior analysts; describe strategies and tactics for providing ethically sound client services; and recommend how behavior analysts can achieve, maintain, and extend their professional competence.

CHAPTER 31

Ethical and Professional Responsibilities of Applied Behavior Analysts

Thomas R. Freeman, Linda A. LeBlanc, and Jose A. Martinez-Diaz

LEARNING OBJECTIVES

- Define ethics and state why ethical practice and codes are important.
- Define and explain standards of professional practice relevant to behavior analysts.
- Explain how professional competence can be ensured.
- Identify and explain ethical issues in client services.
- Explain considerations important to advocating for clients.

Ethical dilemmas surface frequently in the practice of applied behavior analysis. Consider these situations:

- Lee resides in a private, rural, for-profit community-based home for persons with intellectual disabilities. He informs Dr. Han, the facility director, that he wants to move to an affordable apartment in a nearby town. Such a move would represent a loss of income to the agency, might generate additional transition costs (e.g., moving expenses, future on-site supervision), and has the potential to be dangerous, given the spike in the crime rate in the area of town that Lee is considering. How could Dr. Han respond ethically to Lee's request about moving without being biased by a conflict of interest?
- Raluca has begun her supervised fieldwork in preparation for becoming a Board Certified Behavior Analyst (BCBA®). Her supervisor, Anca, is already a BCBA. Recently, Anca has directed Raluca to do more advanced tasks (e.g., assessments, designing programs) that are beyond the material that she has encountered in her coursework. She has not been explicitly taught how to do the tasks that Anca is directing her to complete with clients. Further, given circumstances, Anca is not directly observing her work or providing specific feedback. Raluca is concerned that she will make errors that could impact the quality of her client's programming. What should Raluca do to ensure that she is learning new behavior analytic skills fluently and that her clients have optimal programming? What should Anca have done to mitigate this situation from developing in the first place?
- Ms. Dougherty is a second-year teacher who is also pursuing experience hours toward certification in behavior analysis. During an annual individualized education program (IEP) meeting, she perceives that a school district administrator, Mr. Doyle, is trying to "steer" the parents of a student with emotional disabilities into accepting a revised IEP. Mr. Doyle has removed the recommendation from the team for applied behavior analysis services and replaced it with his own suggestion for sensory-based calming techniques to be provided by a paraprofessional. Ms. Dougherty believes Mr. Doyle's suggestion may be motivated, at least in part, by his desire to contain costs for his tightly budgeted school district, where professional behavior analysis services would represent a costlier intervention for this student. As a second-year teacher, Ms. Dougherty is concerned that if she speaks up, she might upset her principal and possibly lose her job. If she remains silent, however, and does not inform the parents of the team's original recommendation, the student is unlikely to receive needed services. Since she is accruing supervised experience hours, and is, therefore, responsible for behaving in accordance with the Compliance Code of the BACB, how might Ms. Dougherty serve as an effective advocate for the student, while attempting to retain both her faculty position and her credibility with school administrators?

How should the behavior analyst respond in each of these situations? This chapter will help to address that question. We begin by defining ethics and discussing the importance of maintaining ethical and professional standards in the science and practice of applied behavior analysis. We discuss ethical issues within the context of client services (e.g., informed consent, conflict of interest), ethical implications of new technologies, and the need to create professional networks to support ethical behavior.

We thank Timothy E. Heron for his input, and acknowledge Matthew Normand for his contributions to a previous version of this chapter.

WHAT IS ETHICS AND WHY IS IT IMPORTANT?

Ethics Defined

From a behavior analytic viewpoint, **ethics** is defined by specific rules of conduct. These rules can either be broadly stated, as in Koocher and Keith-Speigel's (1998) guiding principles—(1) do no harm; (2) respect autonomy; (3) benefit others; (4) be just; (5) be truthful; (6) accord dignity; (7) treat others with care and compassion; (8) pursue excellence; and (9) accept accountability—or more specifically delineated, as in a professional code of conduct. For applied behavior analysts, The Professional and Ethical **Compliance Code** for Behavior Analysts—hereafter referred to as *The Compliance Code* (see Figure 31.1)—includes 10 sections relevant to professional and ethical behavior across an array of areas.[1]

Figure 31.1 The Professional and Ethical Compliance Code of the Behavior Analyst Certification Board.

1.0 Responsible Conduct of Behavior Analysts
- 1.01 Reliance on Scientific Knowledge
- 1.02 Boundaries of Competence
- 1.03 Maintaining Competence through Professional Development
- 1.04 Integrity
- 1.05 Professional and Scientific Relationships
- 1.06 Multiple Relationships and Conflicts of Interest
- 1.07 Exploitative Relationships

2.0 Behavior Analysts' Responsibility to Clients
- 2.01 Accepting Clients
- 2.02 Responsibility
- 2.03 Consultation
- 2.04 Third-Party Involvement in Services
- 2.05 Rights and Prerogatives of Clients
- 2.06 Maintaining Confidentiality
- 2.07 Maintaining Records
- 2.08 Disclosures
- 2.09 Treatment/Intervention Efficacy
- 2.10 Documenting Professional Work and Research
- 2.11 Records and Data
- 2.12 Contracts, Fees, and Financial Arrangements
- 2.13 Accuracy in Billing Reports
- 2.14 Referrals and Fees
- 2.15 Interrupting or Discontinuing Services

3.0 Assessing Behavior
- 3.01 Behavior-Analytic Assessment
- 3.02 Medical Consultation
- 3.03 Behavior-Analytic Assessment Consent
- 3.04 Explaining Assessment Results
- 3.05 Consent-Client Records

4.0 Behavior Analysts and the Behavior-Change Program
- 4.01 Conceptual Consistency
- 4.02 Involving Clients in Planning and Consent
- 4.03 Individualized Behavior-Change Programs
- 4.04 Approving Behavior-Change Programs
- 4.05 Describing Behavior-Change Program Objectives
- 4.06 Describing Conditions for Behavior-Change Program Success
- 4.07 Environmental Conditions that Interfere with Implementation
- 4.08 Considerations Regarding Punishment Procedures
- 4.09 Least Restrictive Procedures
- 4.10 Avoiding Harmful Reinforcers
- 4.11 Discontinuing Behavior-Change Programs and Behavior-Analytic Services

(continued)

Figure 31.1 (continued)

5.0 Behavior Analysts as Supervisors
- 5.01 Supervisory Competence
- 5.02 Supervisory Volume
- 5.03 Supervisory Delegation
- 5.04 Designing Effective Supervision and Training
- 5.05 Communication of Supervision Conditions
- 5.06 Providing Feedback to Supervisees
- 5.07 Evaluating the Effects of Supervision

6.0 Behavior Analysts' Ethical Responsibility to the Profession of Behavior Analysts
- 6.01 Affirming Principles
- 6.02 Disseminating Behavior Analysis

7.0 Behavior Analysts' Ethical Responsibility to Colleagues
- 7.01 Promoting an Ethical Culture
- 7.02 Ethical Violations by Others and Risk of Harm

8.0 Public Statements
- 8.01 Avoiding False or Deceptive Statements
- 8.02 Intellectual Property
- 8.03 Statements by Others
- 8.04 Media Presentations and Media-Based Services
- 8.05 Testimonials and Advertising
- 8.06 In-Person Solicitation

9.0 Behavior Analysts and Research
- 9.01 Conforming with Laws and Regulations
- 9.02 Characteristics of Responsible Research
- 9.03 Informed Consent
- 9.04 Using Confidential Information for Didactic or Instructive Purposes
- 9.05 Debriefing
- 9.06 Grant and Journal Reviews
- 9.07 Plagiarism
- 9.08 Acknowledging Contributions
- 9.09 Accuracy and Use of Data

10.0 Behavior Analysts' Ethical Responsibility to the BACB
- 10.01 Truthful and Accurate Information Provided to the BACB
- 10.02 Timely Responding, Reporting, and Updating of Information Provided to the BACB
- 10.03 Confidentiality and BACB Intellectual Property
- 10.04 Examination Honesty and Irregularities
- 10.05 Compliance with BACB Supervision and Coursework Standards
- 10.06 Being Familiar with This Code
- 10.07 Discouraging Misrepresentation by Non-Certified Individuals

Rules of ethics describe the personal behavior of individuals, not vague inherent traits or characteristics of individuals or groups. One should not refer to a person or an organization as being either ethical or unethical; these terms describe the behavior of an individual.

The two main approaches to ethics are termed the *deontological* (i.e., acts-oriented) approach and the *utilitarian* or *teleological* (i.e., results-oriented) approach. The deontological approach evaluates the ethicality of behavior based solely on the nature of the act itself regardless of consequences (O'Donohue & Ferguson, 2011; White, 1993). The utilitarian approach judges the rightness or wrongness of a behavior based on its consequences or results.

Both approaches are important for behavior analysts. The deontological approach creates a firm and necessary set of rules

to guide ethical behavior. For example, *The Compliance Code* states that behavior analysts must not accept gifts. However, the utilitarian approach provides needed flexibility when implementing those rules of conduct. In relation to the prohibition regarding acceptance of gifts, it is not difficult to envision a situation where an adult with a developmental disability excitedly presents her behavior analyst with a picture she has drawn, or a young client, shyly gives the behavior analyst a clay statue he made at school as a holiday gift. The behavior analyst may unnecessarily damage the clinical relationship by rejecting such gifts on the grounds of maintaining ethical purity. However, as Lattal and Clark (2007) stated, "Rules alone are neither specific enough nor comprehensive enough to cover all aspects of a difficult ethical decision" (p. 6). The utilitarian approach thus provides a principled way to analyze and resolve ethical questions that are not answered with a simple "yes" or "no." One might consider the deontological approach to be analogous with "the letter of the law," while the utilitarian approach attempts to address "the spirit of the law."

From a philosophical perspective, Skinner (1978, 2005) tended toward the utilitarian view, repeatedly suggesting that ethics govern behavior, and are therefore functionally related to the survival of the individual, group, culture, and species (de Melo, de Castro & de Rose, 2015). When various interests across groups or cultures are not in full agreement, or when different ethical rules conflict, complexities arise. For instance, a behavior that might serve the long-term survival interests of a group may nonetheless work to the short-term detriment of an individual. When a behavior analyst is confronted with a complex ethical question that presents competing, contradictory, or potentially harmful contingencies, effective navigation toward a fair outcome requires a well-calibrated ethical compass and reliable anchor. The behavior analyst must carefully consider who is likely to benefit, who might be potentially harmed, and what guidance is provided by the professional and ethical code of conduct.

Behavior analysts' decisions and actions must always be ethically grounded in the answers to three fundamental questions: What is the right thing to do? What is worth doing? and What does it mean to be a good behavior analyst? (Reich, 1988; Smith, 1987, 1993). The answers to these questions guide each behavior analyst's personal and professional practices based on an overriding principle: to help others learn how to improve their physical, emotional, social, and overall personal condition. As Corey, Corey, and Callanan (1993) stated, "The basic purpose of practicing ethically is to further the welfare of the client" (p. 4).

What Is the Right Thing to Do?

The answer to this question is influenced by many factors, including personal learning histories of right and wrong, the context within which applied behavior analysis is practiced, and the applicable ethical and legal rules of conduct. One makes a determination based on established principles, validated methods, and contact with effective decisions made by other applied behavior analysts and professionals in related fields. The goal is to ensure the welfare of those entrusted to one's care, the integrity and robust growth of the profession, and ultimately the survival of the culture (Skinner, 1953, 2002).

Ethics is ultimately related to cultural practices. Ethical codes may vary between cultures or within a single culture over time. What is acceptable in one culture may not be acceptable in another (e.g., recreational consumption of alcohol). What is acceptable at one point in time may be completely unacceptable 20 years later.

Personal Histories. Each person represents a distinctly different learning history. Thus, each professional should strive to obtain initial and recurrent training and experiences to offset any bias or predisposition that may carry over from our personal or cultural background. For example, a behavior analyst who grew up watching her brother engage in self-injurious behavior (SIB) is now providing services to a child who exhibits similar SIB. She may recall her parents' use of various procedures to help her brother (e.g., use of punishment, exclusion from family outings, psychotropic medication). The potential influence of such personal experience can be reduced effectively, in favor of an unbiased exploration of clinically appropriate treatment alternatives, if the analyst has had proper training in a range of assessment and treatment options.

A practitioner's cultural or religious background may also influence decisions about the right course of action. An individual reared in a family culture based on a "spare the rod and spoil the child" philosophy may react differently to a child's tantrum than if that same individual was raised by parents who took a "he'll grow out of it" approach. With proper training in behavior analysis, his response will likely be less culturally biased and more reflective of a scientific evidence-based approach.

Finally, a person's professional training and clinical experience can influence decision making through such subtle biases as the practitioner's comfort with the use of familiar treatment options. This may lead to decisions that extend beyond proper discriminative control (i.e., the same interventions are used in cases where those treatment options are not best practice). Thus, the practitioner must remain vigilant, aware that personal history, cultural background, and even clinical experience may exert undue influence on the proper delivery of professional service. To counteract these influences, the practitioner should regularly discuss professional issues with colleagues, obtain training, seek supervision or consultation when needed, read recent research literature, and review case studies relating to one's area of professional focus (Bailey & Burch, 2016). If undue influence still presents a problem, the ethical practitioner, after consultation, should consider transferring the case to another provider.

The Context of Practice. Applied behavior analysts work in schools, homes, community settings, job sites, centers, and other environments. Rules within these environments cover myriad response classes (e.g., attendance, use of sick time, use of specific positive or aversive intervention strategies). Included in the rules are policy statements that are designed to help practitioners discriminate between legal issues and ethical issues. For example, some practices may be legal, but unethical. Breaking a professional confidence, accepting valued family "heirlooms" in lieu of payment for services, or engaging in consensual sexual relations with a recently discharged client over age 18 serve as examples of actions that are legal, but unethical. Other actions

are both illegal and unethical. For instance, misrepresenting personal skills or promised services; overbilling for services; stealing the belongings of a client while rendering services; abusing a client physically, emotionally, sexually, or socially; and engaging in consensual sexual interaction with persons under the legal age of consent are all examples of actions that are both illegal and unethical (Greenspan & Negron, 1994). Behavior analysts who can discriminate between these legal and ethical distinctions are more likely to provide effective services, maintain a focused sensitivity toward clients, and not run afoul of the law or professional standards of conduct.

Ethical Codes of Behavior. Professional organizations and associations generate or adopt **ethical codes of behavior**, to provide clear guidelines for their members to follow when deciding a course of proper action in conducting their professional duties. These codes also typically outline the rules and standards by which graduated sanctions may be imposed on members who deviate from the professional code (e.g., reprimand, censure, expulsion from the organization). The Association of Professional Behavior Analysts has adopted the BACB's *Professional and Ethical Compliance Code for Behavior Analysts* (Behavior Analyst Certification Board [BACB], 2014). More discussion of this point is found later in the chapter.

What Is Worth Doing?

Questions related to what is worth doing directly address the goals of practice (i.e., what we hope to accomplish) and the impact of the strategies used to pursue those goals. The answers to these questions are typically based on an evaluation of the existing exigencies, the need for intervention, and an analysis of social validity and cost–benefit ratios that relate to any proposed intervention.

Existing Exigencies. An adult who engages in severe self-injurious behavior, a child with significant feeding problems, or a student who engages in highly disruptive behavior in class each presents a distinct problem-solving challenge to the behavior analyst. Behaviors that are self-injurious or that harm others are unquestionably worthy of swift assessment and intervention. Such dangerous behaviors must ethically be considered as targets for change before other less dangerous or disruptive behaviors are addressed. However, the need to expedite treatment is not an invitation to adopt a form of *situational ethics*, in which the promise of a quick result in the short term compromises one's consideration of the long-term effects of the intervention. For example, a positive punishment procedure may produce an immediate reduction in behavior, but had a careful assessment of the function of the behavior been completed, a less intrusive intervention could have been used. Behavior analysts must, therefore, strike a balance between immediate health and safety concerns, any likely short-term and long-term effects of an intervention, and insuring that any behavioral procedures comply with *The Compliance Code*.

Social Validity. Questions of social validity ask (a) whether the goals of the planned intervention are acceptable; (b) whether procedures are acceptable and aligned with best treatment practices (Peters & Heron, 1993); and (c) whether the obtained results show meaningful, significant, and sustainable change (Wolf, 1978). Most people would agree that teaching a school-age child to read is a desirable goal. Using a measurably effective instructional method such as direct instruction is procedurally sound. Demonstrating marked improvement in reading skill is a socially significant outcome. In every sense, teaching a child or adult to read meets the ethical test for social validity. The new reading skill has a positive effect on the life of the individual.

However, we cannot make the same claim for every skill in every situation. Consider the following real-life examples: A 50-year-old woman with mobility, sight, and hearing problems is being taught to identify various street signs; an elderly patient with Alzheimer's disease is being taught to stack colored rings; a first-grade student with autism receives daily discrete trial instruction on discriminating various sports cars. In each of these cases, the present and future "worth" of the treatment with respect to resources, goals, and outcomes is questionable at best. From an ethical standpoint, the behavior analyst must carefully consider whether a particular goal should be accomplished, and whether the achievement of that goal would be sustainable in the natural environment.

Cost–Benefit Ratio. A cost–benefit analysis is contextual. The behavior analyst must weigh the likely difference between the cost of a treatment or intervention (i.e., resources involved in planning, implementing, monitoring, and evaluating) and the projected benefits (i.e., likely future potential gains by the person). The benefit to the individual should be significant enough to justify the short- and long-term cost of providing the service. For example, we would likely find it ethically difficult to support a plan to transport a student with learning disabilities to an expensive out-of-state private school when comparable services are available as part of the local neighborhood public school system, especially if the move to a different school would not clearly result in significantly improved learning and social behavior outcomes. In another case, an 11th-grade student with developmental disabilities might not be best served by being placed in an academic, college-oriented program, when a more functional individualized curriculum would be far more likely to increase this student's self-sufficiency, independence, and long-term prospects for employment. We would be acting unethically to assign this student to an environment where an overly ambitious academic program is likely to result in escape-related reflexive establishing operations, thereby evoking escape/avoidance behavior—especially when a more functional educational model would effectively help this student meet his individualized short-term and long-term goals. Sprague and Horner (1991) suggested that committees are best suited to address the thorny issues that often arise in a cost–benefit analysis. A committee-based decision-making process can effectively account for a wide range of perspectives that are placed into a hierarchy. This can help ensure that the opinions of those persons with the highest stake in the outcome are given the greatest consideration.

What Does It Mean to Be a Good Behavior Analyst?

Being a good behavior analyst requires more than following professional codes of conduct. While adherence to *The Compliance Code* is necessary, it is not sufficient. Moreover, keeping the client's welfare at the forefront of one's decision-making process is vitally important, but not, in and of itself, sufficient. A good practitioner must be self-regulating (Rosenberg & Schwartz, 2018). This means that the ethical practitioner seeks ways to calibrate decisions over time, making sure to take into consideration a well-informed integration of values, contingencies, rights, and responsibilities (Smith, 1993). In addition, good behavior analysts maintain contact with the evolving professional literature, seek advanced training to improve their skills and practices using a systematic method (Rosenberg & Schwartz, 2018).

Why Is Ethics Important?

Behavior analytic practitioners abide by ethical principles to (a) produce socially significant behavior change that produces contextually relevant and meaningful outcomes for the persons entrusted to their care (Hawkins, 1984), (b) reduce or eliminate specious or questionable interventions and the potential for harm (e.g., poor treatments, injuries to self or others), and (c) conform to the ethical standards of learned societies and professional organizations (https://bacb.com/ethics-code/). Skinner (1953) was concerned with the development of ethics, particularly in relation to those in society who require care and protection. His ethical perspective focused in part on the influence of **countercontrol**, which he defined as occurring when someone responds to coercion or an aversive form of external control by showing "an emotional reaction of anger or frustration including operant behavior which injures or is otherwise aversive to the controller" (p. 321).

Countercontrol is often characterized by the individual "moving out of range, attacking, or passively resisting" (Delprato, 2002, p.192). Skinner stated that countercontrol is naturally evoked in individuals who have the capacity to rebel against exploitative or harsh controlling conditions, but that this capacity is limited or absent in certain groups, such as the elderly, children, individuals with an intellectual disability or a chronic mental health condition, or individuals who are incarcerated. (Skinner, 1976). O'Donohue and Ferguson (2011) extend this conceptualization, concluding that, "in those circumstances where individuals are disadvantaged, such that they have no effective mechanisms of countercontrol, external agencies need to step in to offset this imbalance" (p. 495), which occurs by developing and enforcing ethical codes of conduct.

Ethical codes not only provide guidance on what to do but also help practitioners avoid engaging in "situational ethics" whereby one acts (or does not act) based on expediency, pressure, or misplaced priorities (Maxwell, 2003). By following professional ethical codes, the practitioner increases the likelihood that he or she will deliver appropriate and effective services, which will produce a cumulative social benefit. Over time, these codified rules of conduct are refined through a selection-based process that serves to promote cultural survival. Skinner directly addresses this broader perspective on the importance and function of ethical rules in his discussions on group control and cultural selection.

> Without help a person acquires very little moral or ethical behavior under either natural or social contingencies. The group supplies supporting contingencies when it describes its practices in codes or rules, which tell the individual how to behave, and when it enforces those rules with supplementary contingencies . . . This is all part of the social environment called culture, and the main effect, as we have seen, is to bring the individual under the control of remoter consequences of his behavior. The effect has had survival value in the process of cultural evolution, since practices evolve because those who practice them are as a result better off. (Skinner, 2002, p. 173)

Practitioners should recognize that behaving ethically may not result in direct and immediate reinforcement. Ethical action may in fact disadvantage the practitioner in the short term. For example, a behavior analyst may decline a highly promising business opportunity because it represents a potential conflict of interest, or even the appearance of a conflict. In rejecting this financial opportunity, the behavior analyst exhibits behavior that has come under the control of a set of rules whereby he sets aside immediate gain, choosing instead to abide by ethical standards that, in the long run, elevate the entire community. According to Skinner, such actions promote the survival of the group and, by extension, its cultural practices. Moreover, the benefit to the group redounds back upon the individual behavior analyst in the long run, since "reasonable control over the selfish behavior of the individual is matched by the advantages which he gains as a member of a group which controls the same selfish behavior in others" (Skinner, 1953, p. 327).

STANDARDS OF PROFESSIONAL PRACTICE FOR APPLIED BEHAVIOR ANALYSTS

What Are Professional Standards?

Professional standards are written guidelines or rules that provide direction for conducting the practices associated with an organized profession. Professional societies and certification or licensing boards develop, refine, and revise the standards that govern their profession to provide members with parameters for appropriate behavior in a dynamic and changing environment. In practice, organizations initially form task forces to develop standards that are reviewed and approved by their respective boards of directors and members. In addition to prescribing rules of conduct, most professional organizations exact sanctions on members who fail to follow the rules. Major code violations may result in expulsion from the organization, or revocation of certification or licensure.

Five complementary and interrelated documents describe standards of professional conduct and ethical practice for applied behavior analysts. Two of these documents specify codes of conduct (*Professional and Ethical Compliance Codes for Behavior Analysts, Ethical Principles of Psychologists and Code of*

Figure 31.2 The right to effective behavioral treatment.

The Right to Effective Behavioral Treatment

1. An individual has a right to a therapeutic environment.
2. An individual has a right to services whose overriding goal is personal welfare.
3. An individual has a right to treatment by a competent behavior analyst.
4. An individual has a right to programs that teach functional skills.
5. An individual has a right to behavioral assessment and ongoing evaluation.
6. An individual has a right to the most effective treatment procedures available.

Adapted from "The Right to Effective Behavioral Treatment," by the Association for Behavior Analysis International, 1989. Conduct). Three additional documents are position statements (i.e., *The Right to Effective Behavioral Treatment, Statement on Restraint and Seclusion, The Right to Effective Education*). These documents were published on the following dates.

- *Professional and Ethical Compliance Code for Behavior Analysts* (Behavior Analyst Certification Board [BACB], 2014).
- *Ethical Principles of Psychologists and Code of Conduct* (American Psychological Association, 2010).
- *The Right to Effective Behavioral Treatment* (Association for Behavior Analysis International, 1989).
- *Statement on Restraint and Seclusion* (Association for Behavior Analysis International, 2010).
- *The Right to Effective Education* (Association for Behavior Analysis International, 1990).

Professional and Ethical Compliance Code for Behavior Analysts

According to the preamble in the *Professional and Ethical Compliance Code for Behavior Analysts*, this document "consolidates, updates, and replaces the former BACB's Professional Disciplinary and Ethical Standards and Guidelines for Responsible Conduct for Behavior Analysts" (2014, p. 1). *The Compliance Code* contains 71 elements organized into 10 different sections, "relevant to professional and ethical behavior of behavior analysts, along with a glossary of terms." With an effective date of January 1, 2016, "all BACB applicants, certificants, and registrants will be required to adhere to the Code" (2014, p. 1). (See Figure 31.1.)

The Compliance Code has undergone several revisions over the past decade, changing from unenforceable guidelines, references, and resources to an enforceable document with disciplinary standards. **Disciplinary standards** are statements that affect intellectual property, malpractice, and an expanded compliance system for providing corrective, disciplinary, and revocation actions, depending on the circumstances (BACB, 2014; Carr, Ratcliff, Nosik, & Johnston, in press). The entire *Compliance Code* not only serves as a reference for clients and employers in determining whether a behavior analyst's behavior has been conducted in an appropriate, professional, and ethical manner (Carr et al., in press), but also provides a procedure for the supervised practice of aspiring behavior analysts, handling complaints, and enforcing the code of ethics.

Figure 31.3 Principal areas of endorsement from the ABAI Statement on Restraint and Seclusion.

1. The Welfare of the Individual Served is the Highest Priority
2. Individuals have a Right to Choose
3. The Principle of Least Restrictiveness

Adapted from "Statement on Restraint and Seclusion, 2010," by the Association for Behavior Analysis International. Retrieved October 30, 2017, from https://www.abainternational.org/about-us/policies-and-positions/. Copyright by the Association for Behavior Analysis International. Adapted with permission.

The Right to Effective Behavioral Treatment

The Association for Behavior Analysis International has published two position papers describing client's rights. In 1986, the Association established a task force to examine the rights of persons receiving behavioral treatment and how behavior analysts can ensure that clients are served appropriately. After 2 years of study, the task force outlined six basic client rights as the basis for directing the ethical and appropriate application of behavioral treatment (see Figure 31.2) (Van Houten et al., 1988).

Statement on Restraint and Seclusion

Figure 31.3 shows a portion of the Association for Behavior Analysis International's statement on restraint and seclusion. Overall, this statement underscores ABAI's position that the principles of least restrictiveness, the individual's right to choose, and the overall welfare of the individual are the highest priority.

ENSURING PROFESSIONAL COMPETENCE

Professional competence in behavior analysis is achieved through academic training that involves formal coursework, supervised practica, and mentored professional experience. Even though very few universities house departments of behavior analysis, many excellent behavior analysts have been trained through university-based master's and doctoral-level programs housed in psychology, education, and other human service departments.[2]

Behavior analysis accreditation and credentialing bodies have specified minimum curriculum and supervised experience requirements for behavior analysts. Both the Behavior Analyst Certification Board (BACB) and the Association for Behavior Analysis International Accreditation Board have set minimum standards for what constitutes training in behavior analysis. The BACB credentials individual practitioners, while ABAI Accreditation Board accredits university training programs and verifies that course sequences meet the instructional requirements for certification as set by the BACB. Practitioners must not only meet the certification criteria but also pass a certification examination. The BACB has conducted an extensive occupational analysis and developed the Behavior Analyst Task List, now in its fourth edition—Behavior Analyst Certification Board (BACB), 2012. The Task List specifies the minimum content that all behavior analysts should master (BACB, 2012; Shook, Johnston, & Mellichamp, 2004; cf. Martinez-Diaz, 2003).[3] The fifth edition of the Task List (BACB, 2017) becomes effective January 1, 2022.

Obtaining Certification and Licensure

Potential consumers must be able to identify practicing behavior analysts who have demonstrated at least a minimum standard of training and competence (Moore & Shook, 2001; Shook & Favell, 1996; Shook & Neisworth, 2005). A professional credential publicly identifies those who have met certain requirements in a field (Shook & Favell, 1996). Those seeking professional services often use a profession's credential as a tool in selecting a provider, and employers may use the credential as an efficient means of hiring professionals (Carr et al., in press). This information, combined with the disciplinary action that can occur if a professional acts outside the scope of responsible professional conduct, is designed to enhance public protection. In the past, most behavior analysts in private practice were licensed in psychology, education, or clinical social work. The public had no way to determine whether the licensed professional had specific training in applied behavior analysis (Martinez-Diaz, 2003).

Two distinct categories of professional credentials are important in the field of applied behavior analysis: professional certification and licensure.

Professional Certification

Professional certification is a voluntary credential issued by a private organization that is authorized by members of the profession, not the government. The professional certifying body for applied behavior analysis is the BACB, whose board of directors is composed of behavior analysts and a consumer representative. This international credential crosses state and national borders, offering greater mobility to members of the profession whose credentials might otherwise be restricted to specific areas (Hall & Lunt, 2005). The eligibility requirements for certification are predicated upon educational degree and coursework requirements, supervised experiential training requirements, and passing a psychometrically sound examination (Johnston, Mellichamp, Shook & Carr, 2014). Like other professions, the BACB requires documented continuing educational experiences and professional development, with specific emphasis on the areas of ethics and supervision (Carr et al., in press).

State/National-issued Licenses

A license is a state, provincial, or national government document that is established by law and specifies the privileges and limits of professional practice (Green & Johnston, 2009). A license is a mandatory credential needed to practice, not a voluntary certificate of achievement. Standards for obtaining, maintaining, and legally revoking a license are developed by the designated regulatory board that may or may not include members of the profession. As laws are constantly changing within and across states or nationally, behavior analysts are responsible for remaining up to date with respect to any licensing regulations that govern their practice within that jurisdiction.

Practicing Within One's Areas of Competence

Behavior analysts must practice within their areas of competence, based on professional training, experience, and performance. For example, a behavior analyst with extensive experience working with typically developing adolescents should not begin working with children with autism-related language delays or adults with developmental disabilities without obtaining additional active supervision. The behavior analyst must accrue adequate supervised experience working with any new clinical population. Moreover, an individual with experience only in clinical practice should not begin to provide services in the area of organizational behavior management without additional training and supervision. LeBlanc, Heinicke, and Baker (2012) provide guidance on expanding areas of practice in an ethically responsible manner.

Even when practicing within one's area of competence, situations may arise that exceed one's training or experience. In these cases, the practitioner must either make a referral to another behavior analyst or consultant, or work in close consultation with another provider who has the necessary expertise. Gaps in one's professional training may be addressed by attending workshops, seminars, classes, and other continuing education activities. However, professional situations can arise that are outside a BCBA's experience (see Figure 31.4). At that point, behavior analysts should work with mentors, supervisors, or colleagues who can provide enhanced training, professional development, and guidance.

Developing Competence in Supervision and Mentorship

Recognizing the Need

Behavior analysts often provide supervision for (a) young professionals who are pursuing certification as a behavior analyst, (b) individuals holding paraprofessional-level credentials (e.g., Registered Behavior Technician®), (c) certified behavior analysts who require supervision of their ongoing practice, and (d) non–behavior analysts. Effective supervision of others is critical to the quality of ongoing behavioral services. It contributes to the professional development of the supervisee, the continued growth of the supervisor, and the overall development of our field and its practice, and is recognized in the professional literature (Sellers, Valentino, & LeBlanc, 2016). The supervisor who also fully embraces the role of mentoring is positioned to serve as a life-long counselor through the many challenging professional situations

Figure 31.4 Seeking guidance to handle an unexpected ethical situation.

Presenting Concern	Ethical Problem-solving Strategies
Background: Rhonda recently became employed as a senior behavior analyst for the state. She chairs the local program review committee in District 20, and monitors behavioral services delivered under state authorizations. Voting members of the committee must be *Board Certified Behavior Analysts* (BCBAs). Stanley, a long-time provider in District 20, who was grandfathered under the old state certification rules, always signed his programs in the past as "Certified Behavior Analyst." However, in a recent presentation, Stanley signed his program (which was countersigned by the parents), "Stanley Smith, BCBA." After the program review committee meeting, Rhonda approached Stanley and asked, "Stan, I see that you have signed off as a BCBA. Did you pass the certification exam recently?" Stan answered, "I sent in my certification. You should have it in my file." Rhonda searched and checked the committee files, and other appropriate files, but did not find Stanley's certificate. Rhonda then asked Stanley to provide a copy of his certification, on the chance that it was "lost in the system." He did not comply. Then, she checked the board registry and he was not listed. She asked him to come into the office for a meeting to clarify the situation. He declined. Stanley then filed an age discrimination complaint with the state Equal Employment Opportunity Commission office. What would be Rhonda's best course of action to address this situation?	*Analysis*: Stanley does not appear to be a BCBA, and therefore should not be signing documents as if he were. He did not provide documentation of his certification, he is not listed on the public registry, and he declined to meet with Rhonda to explain the discrepancy between his statement ("I sent in my certification") and the fact that he is not listed in the registry. He is likely in violation of at least *The Compliance Code* 1.04 Integrity, 7.02 Ethical Violations by others and risk of harm, 8.01 Avoiding false or deceptive statements, and possibly 1.02 Boundaries of competence. *Action*: Before taking further action that might escalate the matter, Rhonda would be wise to do two things: (1) She should attempt to verify that Stan indeed does not have a certificate of any kind that could have been legitimately issued in the past under the grandfather clause (basically ruling out that Stan's certificate was lost in the mail or the file somehow); and (2) she should seek guidance from her supervisor in the state service organization to ensure that she follows the proper regulations in dealing with this potential major violation. Under *The Compliance Code* 10.07 Discouraging misrepresentation by noncertified individuals, Rhonda has an ethical responsibility to report Stanley to the BACB immediately. Moreover, Rhonda may have to initiate an investigation by the state of Stanley's billing practices, to be sure that he has been billing appropriately for the level of services he is providing. This may require her to report Stanley directly to the fraud division of a funder. In terms of the discrimination complaint, she would be wise to save and file all documentation of her interactions with Stanley, beginning with the date of her first inquiry. Alerting her supervisor of the disposition of the complaint through *carbon* copies of e-mails or letters would help to ensure total transparency.

that may arise throughout a career. Serving in the role of supervisor requires training, and *The Compliance Code*'s changing standards underscore this need (LeBlanc & Luiselli, 2016).

In response to the need to provide competent training, the BACB convened a workgroup on supervision that recommended several requirements for all certificants providing supervision for those already credentialed, or those pursuing credentials. The requirements were implemented in 2015 and included (a) specific training in supervisory practices prior to supervising others, (b) continuing education in the area of supervision, and (c) a registry that publicly links the BCBA supervisor to his or her supervisee(s).

A special section of the journal *Behavior Analysis in Practice* includes several papers that outline practice recommendations for individual supervision, group supervision, and addressing problems that can arise during the supervisory relationship (LeBlanc & Luiselli, 2016; Sellers, LeBlanc, & Valentino, 2016; Sellers, Valentino, & LeBlanc, 2016; Turner, Fischer, & Luiselli, 2016; Valentino, Sellers, & LeBlanc, 2016).

Developing the Supervisor's Skill Set

The supervisor bears broad responsibility in the supervisory relationship, including the obligation to shape core behavior analytic, conceptual, experimental, and applied repertoires (Sellers, Valentino, & LeBlanc, 2016; Turner et al., 2016). These professional skill sets also include social effectiveness training, public speaking to multiple audiences, time and stress management skills, problem-solving skills, and ethical decision making, among many others (Bailey & Burch, 2010).

Developing these repertoires through in-service training, mentoring experiences, or field-based practica, allows the behavior analyst to be more effective in influencing those who might adopt, implement, or disseminate effective behavioral programming. When these repertoires are actively modeled and explicitly taught to the supervisor-in-training, the likelihood of future professional success of her clients is increased. When these repertoires are compromised, the supervisee does not learn important skills, he may leave the professional altogether, the supervisory relationship may become strained or damaged, and the overall perception of behavior analysis may be hurt (Sellers, Valentino, & LeBlanc, 2016). Sellers, LeBlanc, and Valentino (2016) offer specific suggestions for detecting and remediating these issues throughout the supervisory period (see Figure 31.5).

Section 5.0 of *The Compliance Code* addresses the specific ethical guidelines for supervision by behavior analysts. This section establishes that the "supervisor must take full responsibility for all facets of this undertaking." Sellers, Alai-Rosales, and MacDonald (2016) provide a rationale for each sub-code on supervision with examples of the concerns that might arise if the behavior analyst does not take appropriate action to comply

Figure 31.5 Identifying and managing performance issues in a supervisory context.

Presenting Concern	Ethical Problem-solving Strategies
Background: Jasmina is a BCBA-D who supervises an aspiring behavior analyst, Barry, in his accrual of supervised fieldwork experience hours. Barry has been learning many new concepts and principles along with specific applied procedures to use with clients. Barry implements procedures accurately during therapy sessions, but Jasmina has noticed that Barry is often late to therapy and supervision sessions, makes many errors in data collection, and does not reliably turn in written work products on time. When he does turn in the work, it often has typographical errors or incomplete sentences. This week Jasmina realized that skill acquisition data on a client has not been graphed in several weeks. A casual review of the data sheets indicates that progress stalled over 3 weeks ago, and program changes are well overdue.	*Analysis*: Jasmina realizes that her supervisee has problems in attending, time management and organization skills, and this is affecting his ability to provide appropriate, data-based clinical services. They are failing in their basic ethical responsibilities to clients. While she may catch many of his errors by providing close supervision, she expects that Barry will continue to struggle with these issues once he is no longer closely supervised and is practicing independently. Jasmina identifies her ethical responsibility to her supervisee, the field, and the current and future clients of this supervisee. She must speak with Barry and create a professional development plan to remedy these concerns and help him establish the needed skills. As suggested by Sellers, LeBlanc and Valentino (2016), Jasmina should first reflect on whether she has clearly specified her performance expectations to Barry. If she has not yet given feedback about his late arrivals or poor written work, she should use basic instructions, modeling, rehearsal and feedback to explicitly address his specific problematic repertoires. If she has already provided training and feedback, and his behavior did not change, she may conclude that a more pervasive deficit in time management skills may be having an adverse impact on several of Barry's repertoires. *Action*: Jasmina should talk to him about this in clear and explicit terms, state her desire to help him succeed, and express her concern for the long-term interests of future clients if his problems are not resolved. She might ask whether he has had similar problems in the past. She might also ask to see his time management and scheduling system. If she determines that he has a more global problem with organization, which has a broad impact on his performance (e.g., no system for planning time and tracking tasks and deadlines), Sellers et al. provide recommendations to help develop a support plan. She could assign relevant readings (e.g., David Allen's, *Getting Things Done (2015)*); they could review readings together, and she could help Barry begin to employ new effective strategies. They could select an electronic schedule/notekeeping tool to establish a new system for Barry, with explicit reinforcement contingencies for success at each step in the development plan.

with *The Compliance Code*. For example, sub-code 5.02 refers to appropriate supervisory volume (i.e., a volume of supervisory activities, which is commensurate with the ability to provide high-quality, effective supervision leading to high-quality intervention services). Sellers, Alai-Rosales et al. provide a case example in which a well-intentioned BCBA gradually began to take on too many supervisees. Although her intent was to quickly build to capacity the BCBA-based services in her community, taking on more supervisees than she could effectively oversee resulted in a poor training experience for many of these new professionals. Whether a practitioner overcommits based only on financial pressures or due to a genuine intent to benefit the field, the risk for a poor outcome is equally high.

In another example, Sellers, Alai-Rosales et al. describe the importance of sub-code 5.05, which refers to the importance of communicating the conditions for supervision in writing at the outset of the supervisory relationship (i.e., in a supervision contract) and abiding by those communicated conditions. Conditions and expectations of the relationship must be clearly communicated when the relationship is established. If not, uncertainties arise, leading to disputes regarding required activities, performance criteria and evaluations, and whether or not a supervisor will sign off to verify that experience requirements have been met. If the supervisor and supervisee are not within the same organizational hierarchy (e.g., the supervisor does not directly oversee the clinical work of the supervisee), opportunities for misperception may be even more likely regarding valid activities, actions, and competencies required on the part of the supervisee. Clearly delineated conditions in a contract are critical in producing an effective working relationship. Many ethical dilemmas can arise in supervision, and the supervisor must fully accept the comprehensive responsibility that goes along with this role. The supervisor must proactively seek to ensure the best possible outcome for the supervisee, while ensuring delivery of the highest quality clinical services possible.

The ethics of developing a supervisor's skill set applies to the second scenario at the beginning of the chapter. Anca is not providing Raluca adequate supervision. She would have done far better had she communicated, in writing, the conditions and expectations for both herself and the supervisee at the outset of their supervisory relationship, based on the standards provided by the BACB—and followed those guidelines. Moreover, she should have assigned Raluca only to tasks for which she was adequately trained. At this point in the scenario, Raluca must inform Anca that she requires additional assistance, most likely in the form of hands-on supervision as required by the BACB's own guidelines. If Anca's supervision behavior does not immediately improve, Raluca will probably need to find a new, competent supervisor, and may need to report Anca to the BACB for providing inadequate supervision.

Maintaining and Expanding Professional Competence

Behavior analysts have an ethical responsibility to stay informed of advancements in the field. For example,

conceptual advances and technical innovations in areas such as functional analysis, motivating operations, and applications of the matching law have had profound implications for clinical and educational practice. Behavior analysts can maintain and expand their professional competence by earning continuing education credits, attending and participating in professional conferences, reading professional literature, and presenting cases to peer review and oversight committees.

Continuing Education Units

Behavior analysts can expand their professional competence and keep abreast of new developments by attending training events offering continuing education unit (CEU) credits. The BACB requires a minimum number of CEUs per recertification cycle to maintain certification. Types of continuing education include university coursework, CE issued by BACB-approved continuing education providers, instruction of either of the preceding types, CE issued by the BACB directly, scholarly activities such as publishing or reviewing articles for a journal, and taking and passing the BACB's certification exam again. Continuing education units demonstrate that the behavior analyst has added relevant awareness, knowledge, and/or skills to his or her repertoire. The BACB now requires CEUs in the areas of ethics and supervision during each renewal cycle, which is a testament to the growing importance of these two areas as critical to effective functioning of an applied behavior analyst.

Attending and Presenting at Conferences

Attending and participating in local, state, or national conferences enhance every behavior analyst's skills. The axiom "You never learn something so well as when you have to teach it" continues to have value. Hence, participating in a conference helps practitioners refine their skills.

Professional Reading

Self-study is a fundamental way to maintain currency in an ever-changing field. In addition to routinely reading *Behavior Analysis in Practice*, the *Journal of Applied Behavior Analysis* and *Perspectives on Behavior Science* (formerly published as *The Behavior Analyst*), all behavior analysts should study other behavioral publications specific to their areas of expertise and interest.

Oversight and Peer Review Opportunities

When behavior analysts approach a difficult problem, they apply skills and techniques within their repertoire to address the problem. For example, a behavior analyst may successfully fade out the use of a protective helmet with a child who has long engaged in frequent and severe face-slapping by using differential reinforcement of alternative behavior (DRA) to increase preferred-object holding and play activity by the child. Fading the safety-based helmet presents no ethical problems as long as the technique remains conceptually systematic, is tied to the published research literature, and is effective. However, even the most technically proficient and professionally careful practitioner is subject to contingencies that can lead to treatment drift or error. This is where oversight and peer review come into play.

Many states have laws requiring that oversight be provided under specific circumstances, which are often defined by the type and severity of behaviors being addressed and/or the restrictiveness or intrusiveness of the procedure(s) being proposed. However, the presence or absence of laws in a particular jurisdiction should not determine our dedication to a process of peer review and oversight. This type of professional monitoring protects (1) the consumers of behavior analytic services by ensuring the use of valid and appropriate procedures; (2) the individual behavior analyst, by providing both helpful feedback and administrative support and back-up; and (3) the field in general, in reducing the likelihood of lawsuits or scandal based on the rogue use of untested, inappropriate, and possibly dangerous treatment options.

When findings are presented before a group of colleagues, professionals, or other stakeholders outside the behavior analytic community, the practitioner must outline the use of procedures that comply with clinical and professional standards. Such presentations also provide the behavior analyst an opportunity to clarify behavioral outcomes, present graphic displays that are easy to interpret, and explain the rationale for the various educational or clinical choices in clear language, free of jargon.

Making and Substantiating Professional Claims

Sometimes overzealous or overly confident behavior analysts make preemptive claims that are not realistic. For example, asserting, "I am certain I can help your son" is almost certainly an unethical claim, especially prior to conducting a full functional assessment. A more ethical and appropriate statement may be, "I have had success working with other children who have profiles similar to your son's." A behavior analyst who is experienced in working with a particular population, skilled in the careful process of identifying functional relations, and well acquainted with the salient professional literature is less likely to make unsubstantiated or exceedingly ambitious claims.

This professional standard also relates to those situations where an individual makes a false or deceptive claim to having a certification, license, educational background, or type of training that the individual does not have. Making dishonest statements or claims relating to one's professional experience or credentials is always unethical and, as likely fraudulent conduct, may be illegal. This will be discussed more fully in the section below.

ETHICAL ISSUES IN CLIENT SERVICES

Although applied behavior analysis shares many ethical concerns with other disciplines, ethical considerations that are specific to behavior analysis do arise. Behavior analysts often address skills or problem behavior in contexts where privacy can be a significant concern (e.g., toileting, dressing) or where best-practice guidelines suggest the use of certain evidence-based, but potentially controversial, interventions (e.g., use of an aversive procedure to reduce a life-threatening behavior). Clinical decision making often poses ethical questions, which must be addressed prior to implementation (Herr, O'Sullivan, & Dinerstein, 1999; Iwata, 1988; Repp & Singh, 1990). Reading and referring to *The Compliance Code* and the Task List on a regular basis helps the practitioner maintain a strong ethical foundation.

Informed Consent

Any discussion of service delivery must begin with the issue of consent. A potential recipient of behavioral services, or a participant in a research study, must provide explicit written and signed permission before any assessment, treatment, or research participation may begin. This formal permission to begin any aspect of treatment—assessment, intervention, evaluation—is termed **informed consent**, and requires that full disclosure of all pertinent information be provided to the individual prior to a granting of permission. Figure 31.6 shows a basic example of an informed consent form in which such information is provided.

Three tests must be met before informed consent can be considered valid: (a) The person must demonstrate the *capacity to decide*, (b) the person's decision must be *voluntary*, and (c) the person must have adequate *knowledge* of all salient aspects of the treatment.

Capacity to Decide

To be considered capable of making an informed decision, a participant must have (a) an adequate mental process or faculty by which he or she acquires knowledge, (b) the ability to select and express his or her choices, and (c) the ability to engage in a rational process of decision making. Behavior analysts consider concepts such as "mental process or faculty" to be hypothetical constructs (i.e., mentalism), and there are no widely accepted evaluative tools for testing one's preintervention capacity. However, capacity is most likely to be questioned if an individual "has impaired or limited ability to reason, remember, make choices, see the consequences of actions, and plan for the future" (O'Sullivan, 1999, p. 13). A person is considered mentally incapacitated if a disability affects his or her ability to understand the consequences of his or her actions (Turnbull & Turnbull, 1998).

According to Hurley and O'Sullivan (1999), "Capacity to give informed consent is a fluid concept and varies with each individual and proposed procedure" (p. 39). A person may have the capacity to consent to a positive reinforcement program that poses little or no risk, but may not have the capacity to make decisions on more complex treatment alternatives such as the manipulation of motivating operations or use of punishment. Practitioners should not assume that a person who is capable of giving informed consent in one set of circumstances can provide truly informed consent in all cases.

Evaluation of capacity must be viewed within both a legal and a behavioral context. Courts have held that capacity, in relation to legal competence, requires "the subject to understand rationally the nature of the procedure, its risks, and other relevant information" (*Kaimowitz v. Michigan Department of Mental Health*, 1973, p. 150; Neef, Iwata, & Page, 1986). Thus, operationally, capacity is often determined in relation to the individual meeting the "knowledge" requirement (see below). The determination of capacity in persons with intellectual disabilities poses specific challenges, and the behavior analyst would benefit from consulting a legal expert whenever a question of capacity arises.

When a person is deemed incapacitated, informed consent may be obtained either through a surrogate or a guardian.

Surrogate Consent. *Surrogate consent* is a legal process by which another individual—the surrogate—is authorized to make decisions for a person deemed incompetent, based on the knowledge of what the incapacitated person would have wanted. Family members or close friends most often serve as surrogates.

Figure 31.6 Informed consent form.

(Name of agency/provider)

Informed Consent Form

CLIENT: ______________________________ DOB: __________

STATEMENT OF AUTHORITY TO CONSENT: I certify that I have the authority to legally consent to assessment, release of information, and all legal issues involving the above-named client. Upon request, I will provide (provider/agency) with proper legal documentation to support this claim. I further hereby agree that if my status as legal guardian should change, I will immediately inform (provider/agency) of this change in status and will further immediately inform (provider/agency) of the name, address, and phone number of the person or persons who have assumed guardianship of the above-named client.

TREATMENT CONSENT: I consent for behavioral treatment to be provided for the above-named client by (provider/agency), and its staff. I understand that the procedures used will consist of manipulating antecedents and consequences to produce improvements in behavior. At the beginning of treatment behavior may get worse in the environment where the treatment is provided (e.g., "extinction burst") or in other settings (e.g., "behavioral contrast"). As part of the behavioral treatment, physical prompting and manual guidance may be used. The actual treatment protocols that will be used have been explained to me.

I understand that I may revoke this consent at any time. However, I cannot revoke consent for action that has already been taken. A copy of this consent shall be as valid as the original.

PARENT/GUARDIAN: ______________________________ DATE: __________

WITNESS: ______________________________ DATE: __________

In most states, a surrogate's authority is limited. A surrogate may not authorize treatment when the client is actively refusing treatment (e.g., when an adult with developmental disabilities refuses to sit in a dentist's chair, a surrogate cannot consent to sedation); or for controversial medical procedures such as sterilization, abortion, or certain treatments for mental disorders (e.g., electroconvulsive therapy or psychotropic medication) (Hurley & O'Sullivan, 1999). The surrogate is required to consider specific information when making decisions. For a person who is incapacitated, the landmark case of *Superintendent of Belchertown State School v. Saikewicz* (1977) crystallized factors that surrogates must consider when making informed consent decisions for persons who cannot make their own decisions (Hurley & O'Sullivan, 1999). Figure 31.7 lists necessary information for the two primary areas of concern for surrogates: (a) decision making for a person who is incapacitated and whose wishes may be known or inferred and (b) decision making for a person whose wishes are unknown and probably unknowable (e.g., a person with a profound and lifelong developmental disability).

Guardian Consent. *A guardian is* an individual or organization named by order of the court to exercise any or all powers and rights over the person and/or estate of an individual (National Guardianship Association, 2016). Guardianship is a complex legal issue that varies by jurisdiction. Thus, we will address only two main points regarding guardianship.

First, guardianship may be limited in any way that the court deems appropriate. In most states, a full guardian is responsible for essentially every important decision in a person's life. The court, in protecting the rights of the individual, may determine that limited or temporary guardianship is more appropriate. For example, guardianship may apply only to financial or medical concerns, and may remain in effect only so long as a very specific concern is at issue (e.g., need for surgery). Guardians may not deny basic human rights, such as the right to freedom from abuse or the right to privacy.

Second, when treatment is deemed necessary for an individual who lacks capacity, but that individual refuses treatment, surrogate consent is insufficient. Only a guardian may provide oversight and consent in this situation. The greater the degree of guardianship, the less legal control a person has over his or her own life. Insofar as a major goal of behavior analysis is to increase the independence of those we serve, guardianship of any kind should be considered only when absolutely necessary, and at the most limited level that still resolves the issue.

In all guardianship cases, the court is the ultimate decision-making body and may take any action, including revoking guardianship or determining who should serve as the guardian (O'Sullivan, 1999).

Voluntary Decision

Consent is considered voluntary when it is given in the absence of coercion, duress, or any undue influence and when it is issued with the understanding that it can be withdrawn at any time. "Revocation of consent has the same effects as an initial refusal to consent" (Yell, 1998, p. 274).

Family members, doctors, support staff, or others may exert strong influence over a person's willingness to grant or

Figure 31.7 Factors surrogates must consider when making informed consent decisions for persons who are incapacitated.

<u>FOR A PERSON WHOSE WISHES MAY BE KNOWN OR INFERRED</u>

1. The person's current diagnosis and prognosis.
2. The person's expressed preference regarding the treatment issue.
3. The person's relevant religious or personal beliefs.
4. The person's behavior and attitude toward medical treatment.
5. The person's attitude toward a similar treatment for another individual.
6. The person's expressed concerns about the effects of his or her illness and treatment on family and friends.

<u>FOR A PERSON WHOSE WISHES ARE UNKNOWN AND PROBABLY UNKNOWABLE</u>

1. The effects of the treatment on the physical, emotional, and mental functions of the person.
2. The physical pain that the person would suffer from the treatment or from the withholding or withdrawal of the treatment.
3. The humiliation, loss of dignity, and dependency the person is suffering as a result of the condition or as a result of the treatment.
4. The effect the treatment would have on the life expectancy of the person.
5. The person's potential for recovery, with the treatment and without the treatment.
6. The risks, side effects, and benefits of the treatment.

Adapted from "Informed Consent for Health Care," by A. D. N. Hurley and J. L. O'Sullivan, 1999, in R. D. Dinerstein, S. S. Herr, and J. L. O'Sullivan (Eds.), *A Guide to Consent*, pp. 50–51. Washington DC, American Association on Intellectual and Developmental Disabilities.

deny consent (Hayes, Adams, & Rydeen, 1994). For example, individuals with developmental disabilities may be asked to make major decisions during interdisciplinary team meetings. The way questions are posed to the individual may suggest subtle or not-so-subtle pressure to provide consent (e.g., "This will really help you. You agree with all of us on this, right?"). Therefore, the practitioner should consider discussing issues requiring consent with the individual and an independent advocate in a smaller, private setting. The discussion should not be constrained by time limits, or indicate a need for a quick approval. The prospective service recipient should be given an opportunity to take time to think, discuss, and review all options with a trusted confidant. These steps help ensure that consent is voluntary.

Knowledge of the Treatment

A person considering behavioral services or participation in research must be provided information in clear, nontechnical language regarding: (a) all important aspects of the planned treatment, (b) all potential risks and benefits of the planned procedure or research protocols, (c) all potential evidence-based alternative treatments, and (d) the right to discontinue treatment at any time. Once information has been provided, the individual must demonstrate an understanding of that information, which clearly relates back to an assessment of that individual's capacity. The person must be able to describe the procedures in his or her own words, and correctly answer questions about the plan. For example, if a time-out procedure is suggested, the client should be able to describe how and when the time-out will be implemented. Instead of saying, "I'll get in trouble if I hit another person," the individual should say, "If I hit somebody, I have to go sit over there for 2 minutes, and then I can come back." Figure 31.8 outlines additional information that the behavior analyst should provide to the potential service recipient to ensure voluntary, informed consent (Cipani, Robinson, & Toro, 2003).

As part of providing information for consent, the behavior analyst should always do a **risk–benefit analysis**—that is, weighing the potential harm to the client (or others) versus the benefits likely to result from implementing those procedures—prior to conducting the assessment or intervention.[4] Bailey and Burch (2016) encourage conducting a risk–benefit analysis of four key areas: (1) the general risk factors for behavioral treatment, (2) the benefits of behavioral treatment, (3) the risk factors for each behavioral procedure, and (4) a reconciliation of the risks and benefits with key parties involved. This analysis should occur prior to initial or subsequent requests for informed consent, and repeatedly throughout the delivery of services. For example, a descriptive assessment has few risks, and can help determine factors that trigger or maintain behavior. However, it does not provide a clear demonstration of functional relations.

Alternatively, a full functional analysis, in which antecedents and consequences are systematically manipulated, can clearly demonstrate functional relations, but is also likely to evoke a short-term increase in the problem behavior, with limited potential for triggering a major behavioral episode, possible injury, or other iatrogenic (i.e., intervention-induced) effects.

A risk–benefit analysis must always be done when choosing one evidence-based treatment option over another. This type of analysis assists the practitioner in choosing the least restrictive option that is most likely to be effective.

Treatment Without Consent

Most states have policies authorizing a course of action when an individual cannot, or will not, provide informed consent for a necessary treatment. Typically, consent may be granted in the case

Figure 31.8 Information for clients to ensure informed consent.

The behavior analyst helps to ensure the validity and clarity of informed consent by completing the following tasks:

- Generates appropriate documents that are understandable in the person's primary language and that make clear all elements of the program, including who will deliver the services, their qualifications, under what conditions services will be rendered, the length of the proposed intervention, risks and benefits, and how the program will be evaluated.
- Ensures that all consent documents are discussed in a private setting, and, if necessary, with a family member, third-party advocate, or other witness present, as chosen by the service recipient, who may provide counsel and/or assistance.
- Schedules the consent meeting at a time and location that is convenient for the service recipient. This meeting should allow adequate time for all questions to be addressed, and for adjustments or alternatives to the proposed treatments to be considered.
- Documents in writing the responsibilities of the behavior analyst and the service recipient, including: How confidentiality will be handled (i.e., who has access to records); provisions for a renewed consent if, for example, new data emerge that have the potential to change the proposed intervention; and any issues associated with remuneration, communication (e.g., during and after the intervention), cancellation of appointments, or termination of services.
- Provides a copy of the signed and dated consent form at the conclusion of the meeting.

Adapted from *Ethical and Risk Management Issues in the Practice of ABA*, by E. Cipani, S. Robinson, and H. Toro, 2003. Paper presented at the annual conference of the Florida Association for Behavior Analysis, St. Petersburg, FL. Adapted with permission of the authors.

of a life-threatening emergency, or when a risk of serious harm is imminent. In selected jurisdictions, if a school district determines that certain services are necessary (e.g., special education programming), but the parents refuse, the district may have recourse through a process of progressive administrative review, mediation, and ultimately court action (Turnbull & Turnbull, 1998). As in all aspects of our work, providing treatment without consent requires the practitioner to consult and follow all applicable and current local, state, and national laws and regulations. These may differ across various jurisdictions and are subject to change over time.

Confidentiality

Professional relationships require **confidentiality**, meaning that any information regarding an individual receiving or having received services may not be discussed with, or otherwise made available to, any third party, unless that individual has provided explicit authorization for release of that information. Although confidentiality is a professional ethical standard for behavior analysts, it is also a legal requirement in many jurisdictions (Koocher & Keith-Spiegel, 1998). Figure 31.9 shows a standard release of information (ROI) form. Note that the ROI form clearly specifies what can be shared and released, and the expiration date for such releases.

Limits to Confidentiality and Legal Disclosures

Prior to the initiation of services, the behavior analyst must explain the limits of confidentiality to the client, document the meeting, and ensure that the client signs and dates the document. Disclosure of confidential information may occur without consent for a valid purpose, defined by the following conditions: (1) as mandated by law, (2) to comply with a court order, (3) when credible information suggests imminent harm or danger to the client or another person, (4) when an immediate crisis develops, or (5) when third-party payment for services is involved. For instance, if a student informs a school-based behavior analyst in confidence that another student has a loaded gun in the building, then confidentiality must be breached to protect the safety of students, staff, and administrators (cf. *Tarasoff v. Regents of the University of California, 1976*). Whenever such a disclosure is necessary, one should limit the disclosure to the absolute minimum information necessary to meet the requirement of the valid purpose.

Limits to disclosure also relate to third-party funding sources, which are entities other than the client or client guardian that pay for services. Typically, third-party entities have only limited access to confidential material pertaining to basic client information, the validation of the delivery of services, and payment for those services. Often, other treatment-specific information may only be provided to a third party if a formal release is signed by the "first-party" (i.e., the recipient of services or his or her guardian).

Maintaining Confidentiality

The practitioner must ensure that proper safeguards are in place to protect client confidentiality, including, but not limited to, storing hard-copy records in locked file cabinets, using only password-protected computer files, using encrypted files whenever possible, avoiding transmission of identifiable client information across any wireless systems, and confirming the identity of, and authorization for, any potential recipient of client-specific information.

Figure 31.9 Release of information form.

(Name of agency/provider)

RELEASE OF INFORMATION AND ASSESSMENT CONSENT FORM

CLIENT: ______________________________ DOB: __________

PARENT/GUARDIAN NAME: ______________________________

I consent for the above-named client to participate in an assessment through (provider/agency). I consent to have the assessment with the above-named individual conducted at the following locations (Circle relevant ones)

Home School Other: __________

I understand and consent to have the individuals responsible for care in the above-named locations involved in the assessment of the above-named client. In order to coordinate the assessment with these individuals, I authorize the release of the following confidential records to the individuals responsible for care in the above-named locations:

Evaluations/Assessments: ______________________________

IEP or Other Records: ______________________________

Other: ______________________________

I understand that these records may contain psychiatric and/or drug and alcohol information. I understand that these records may also contain references to blood-borne pathogens (e.g., HIV, AIDS). I understand that I may revoke this consent at any time; however, I cannot revoke consent for action that has already been taken. A copy of this release shall be as valid as the original. THIS CONSENT AUTOMATICALLY EXPIRES 30 DAYS AFTER TERMINATION OF SERVICES or after ONE CALENDAR YEAR.

PARENT/GUARDIAN: ______________________________ DATE: __________

BOX 31.1

When Use of Social Media Results in Breach of Confidentiality

Rebecca, a young BCBA, is excited that her 7-year-old client Jarod is making so much progress in acquiring language. She takes a selfie with Jarod and his family at a school picnic, and posts it on Instagram, with the family's verbal consent. Does this raise an ethical issue? Verbal consent is clearly not sufficient. Others may appear in the background of the photo, and have not given consent. Moreover, the family members might decide that they do not want to advertise to both friends and strangers that their child is the recipient of behavioral services (and thus a potential target for exploitation or abuse).

Louis is an aging BCBA from a state residential facility that closed 30 years ago, who now posts old pictures of staff and clients on a Twitter feed titled "Staff Reunion from State Institution X." Great pictures! Everyone loves to see them and share memories. Many of the individuals in these pictures have already passed away. Has Louis breached confidentiality here? The answer is almost certainly "yes." But is there real harm? What if Louis did a Google search on "images from State Institution X" and found pictures of his old clients already available on the Internet? Would posting those pictures on Twitter be an ethical breach? There is no way to evaluate the potential harm; but without a release from the client, this is an unauthorized breach of confidentiality.

The Health Insurance Portability and Accountability Act of 1996 (HIPAA), Public Law 104-191, specifically pertains to confidentiality of medical information and records. Many ABA-based services are delivered under the umbrella of medically authorized services (e.g., commercial insurance, Medicaid, other state funding). In these cases, practitioners must be careful to follow all HIPAA requirements, lest they sustain hefty fines and legal sanctions.

New and heretofore unforeseen challenges to confidentiality have arisen in recent years with the inexorable growth in the use of social media (see Box 31.1). Later in this chapter we will discuss issues relating to maintaining confidentiality in this expanding global landscape of public communication networks.

Breaches of Confidentiality

Breaches of confidentiality apply to two main response classes: (a) valid disclosures without consent and (b) unintentional breaches resulting from carelessness, misunderstanding of confidentiality requirements, or negligent disregard. For example, an unintentional and careless breach might occur if a behavior analyst provides confidential information to a parent about a child's status, without confirming that the parent requesting the information is the de facto legal guardian for the child. The behavior analyst should have been aware of who has authorized access, and release protected information only after confirming proper authorization.

Legally, all professionals must report suspected child abuse. Even in cases where the child fears repercussions if the abuse is reported, professionals at any level must step forward and report such cases to the authorities. Maintaining confidentiality when a child's health, safety, or welfare is involved does not apply. Figure 31.10 shows a sample form documenting the information provided to the client relating to abuse-reporting requirements.

Figure 31.10 Example of abuse-reporting protocol form.

(Name of agency/provider)

Confidentiality Act/Abuse-Reporting Protocol

Client: ____________________

I understand that all information related to the above-named client's assessment and treatment must be handled with strict confidentiality. No information related to the client, either verbal or written, will be released to other agencies or individuals without the express written consent of the client's legal guardian. By law, the rules of confidentiality do not hold under the following conditions:

1. If abuse or neglect of a minor, disabled, or elderly person is reported or suspected, the professional involved is required to report it to the Department of Children and Families for investigation.
2. If, during the course of services, the professional involved receives information that someone's life is in danger, that professional has a duty to warn the potential victim.
3. If our records, our subcontractor records or staff testimony are subpoenaed by court order, we are required to produce requested information or appear in court to answer questions regarding the client.

This consent expires 1 year after signature date below.

____________________ ____________________

Parent/Legal Guardian Date

Figure 31.11 Defining an acceptable treatment environment.

1. The environment is engaging: Reinforcement is readily available; problem behaviors are reduced; reinforcement contingencies are effective; exploratory play and practice flourish; the environment is by definition humane.
2. Functional skills are taught and maintained: Environments are judged not by paperwork or records, but by observed evidence of training and progress; incidental teaching allows the natural environment to support skill acquisition and maintenance.
3. Behavior problems are ameliorated: A purely functional approach regarding both behaviors and procedures leads to effective interventions; arbitrary labels based on topographies are replaced by individualized definitions based on function.
4. The environment is the least restrictive alternative. Again, this is functionally defined, based on freedom of movement and activity engagement parameters; community settings may actually be more restrictive than institutional ones, depending on their behavioral effects.
5. The environment is stable. Changes in schedules, programs, peers, caregivers, etc., are minimized; skills are maintained; consistency and predictability valued.
6. The environment is safe: Physical safety is paramount; supervision and monitoring are adequate; peer review ensures that proper program procedures are based on function.
7. The client chooses to live there: Efforts are made to determine client choice; alternative environments are sampled.

Protecting the Client's Dignity, Health, and Safety

Dignity, health, and safety issues often center on the contingencies and physical structures present in the environments in which people live and work. The behavior analyst should be acutely aware of these issues. Favell and McGimsey (1993) provided a list of acceptable characteristics of treatment environments to ensure dignity, health, and safety (see Figure 31.11).

Dignity can be examined by addressing the following questions: Do I honor the person's choices? Do I provide adequate space for privacy? Do I look beyond the person's disability and treat the person with respect? Behavior analysts can help to ensure dignity for their clients by defining their own roles. By using operant principles of behavior, they teach skills that will enable learners to establish increasingly effective control over the contingencies in their own natural environments. Everyone has the right to say yes, no, or sometimes nothing at all (cf. Bannerman, Sheldon, Sherman, & Harchik, 1990).

Choice is a central principle in the delivery of ethical behavioral services. In behavioral terms, the act of making a choice requires that both behavioral and stimulus alternatives be possible and available (Hayes et al., 1994). Practitioners must provide the client with behavioral alternatives, and the person must be capable of performing the actions required by the alternatives. To leave a room, a person must be physically capable of opening the door, and the door must not be blocked or locked. The term *stimulus alternatives* refers to the simultaneous presence of more than one stimulus item from which to choose (e.g., choosing to eat an apple instead of an orange or pear). To have a fair choice, a client must have alternatives, must be able to perform each alternative, and must be able to experience the natural consequences of the chosen alternative.

Negligence represents a failure to demonstrate professional integrity on the part of the provider, and threatens the client's health and safety [see *The Compliance Code* 1.04(c)]. Negligence is typically exhibited as nonfeasance—not doing what ought to be done. For instance, a behavior analyst may take on too many cases, and not adequately monitor progress for those cases; or he may not have planned for adequate clinical coverage during his vacation, leaving clients without access to services during those weeks; or perhaps she abruptly terminates a case without consideration for the client's need for a slower fade-out of services. Additionally, negligence can sometimes be demonstrated when acting in an imprudent fashion. For example, an inexperienced analyst might escort too many clients on a community outing, and lacking appropriate supervision, one of the clients wanders away. This was not the intention of the escort, but by not providing adequate supervision, a negligent act occurred.

While negligence is typically unintentional, **fraudulent conduct** is characterized as intentional, willful, and deceitful behavior, and can cause harm to another individual. Misrepresenting one's credentials, training, or background to a recipient of services is a form of fraud, as is overbilling or falsifying client records. Less obvious forms of fraudulent conduct, such as minor falsifications of raw data (e.g., a data collector fills in a data sheet well after the observational period has ended) may or may not result in formal sanctions, but still constitute a clear breach of professional ethics. When an investigation leads to a finding of negligence or fraudulent conduct on the part of a practitioner, professional sanctions are nearly certain, and legal action resulting in fines or even prison is possible, depending on the circumstances and the degree of demonstrated harm.

COORDINATING WITH OTHER PROFESSIONALS

Behavior analysts are often required to work with a myriad of other professionals, many of whom subscribe to scientifically supported treatments. Such collaborations among interdisciplinary team members can result in a variety of positive educational and behavioral outcomes for individuals with disabilities (Brodhead, 2015; Hunt, Soto, Maier, & Doering, 2003) and promote treatment fidelity as well (Kelly & Tincani, 2013).

For example, behavior analysts often coordinate with medical professionals, particularly when the client is receiving psychotropic medication to address problem behavior. Behavior analysts must be sensitive to the fact that the medical professionals follow their own professional ethical code, as does each professional member of any treatment team. Effective coordination between disciplines can only occur if communication among all treatment team members remains clear and frequent, particularly in relation to any proposed "changes in medication regimens, therapies, or programming." (Newhouse-Oisten, Peck, Conway, & Frieder, 2017, p. 148).

Behavior analysts may also interact with staunch proponents of nonbehavioral treatments for which solid evidence of effectiveness is unknown, ignored, or unreliable and therefore invalid. In these situations, behavior analysts must call upon their technical skills, social interaction skills, and *The Compliance Code* when formulating a comprehensive plan for the client. *The Compliance Code* [2.09(d)] states, in part, that behavior analysts have a responsibility to "review and appraise the effects of any treatments about which they are aware that might impact the goals of the behavior-change program" (BACB, 2014, p. 9). Newhouse-Oisten et al. (2017) suggest that behavior analysts must focus on two aspects of each suggested intervention: "whether or not the intervention is supported by research evidence, and whether or not the intervention change is compatible with other interventions" (p. 150). This type of analysis is a clear ethical imperative when determining best practice, but can sometimes cause conflict within a treatment team. Brodhead (2015) provides a series of yes-no questions in a flow chart for evaluating such unknown treatments in an unbiased and objective manner: (1) What is the nonbehavioral treatment? (2) Is the client's safety at risk? (3) Are you familiar with the treatment? (4) Being now familiar with the treatment, have new safety concerns been revealed? (5) Is treatment success possible when nonbehavioral treatment is translated into behavioral processes? (6) Are the impacts to the client sufficient to justify the possibility of compromising the professional relationship? Brodhead also provides a checklist for analyzing proposed treatments and suggests options for ethical action by behavior analysts.

An alternative, but similar, approach is provided by Schreck and Miller (2010), who provide a flow chart to help the practitioner evaluate the validity of three aspects of the proposed but unknown treatment: (1) the underlying theory, (2) the treatment techniques, and (3) the claims of effectiveness.

Box 31.2 offers additional guidelines for professionals to help parents, teachers, and others to evaluate alternative treatment recommendations that may arise.

The best interests of the client will be served when the behavior analyst uses one of these models, or an alternative effective and structured approach, to help guide collaboration with other professionals in a way that enhances client services and reflects well on the field. However, in rare cases, the alternative approach is so disruptive to the effective delivery of behavioral services that the practitioner must withdraw from the case, providing the client with clear and valid reasons for doing so.

This approach to coordinating with other professionals can be applied to the third scenario described in the opening of the chapter. Ms. Dougherty is in a bind, but she only "perceives" the intent of the school administrator with whom she has to coordinate services. She should continue to advocate for the best interests of

BOX 31.2

Guidelines for Professionals to Help Parents, Teachers, and Other Caretakers

Parents, teachers, and other caretakers are not without resources when trying to ascertain whether a particular treatment meets the standard for best practice, or falls within the scope of a fad or untested intervention. Three resources follow.

First, change agents can consult a trusted behavior analyst and the corresponding Code of Conduct that he or she follows. *The Compliance Code* states that, "Behavior analysts always have the obligation to advocate for and educate the client about scientifically supported, most effective treatment procedures" [*The Compliance Code* 2.09(a)]. Moreover, *The Compliance Code* 6.02 states: "Behavior analysts promote behavior analysis by making information about it available to the public through presentations, discussions, and other media." So, when change agents follow the advice of a behavior analyst, they increase the chances that the recommendations they receive meet quality care criteria.

Second, Schreck and Mazur (2008) suggest a series of six strategic techniques to counter the proliferation of fad/alternative treatments: (1) compare the effectiveness of the treatment in question with ABA; (2) emphasize the long-term cost effectiveness of ABA; (3) publicize results of these comparisons via mass media; (4) market ABA to parents and employers; (5) find a way to short-circuit the search for an "easy way out" solution and the influence on this by mass media; and (6) educate BCBAs on the ethical dilemmas and consequences of using nonsupported treatments.

Finally, Heron, Tincani, Peterson, and Miller (2005) suggest that all interventionists develop what noted astronomer, Carl Sagan, termed a "Baloney Detection Kit"—a kind of toolbox of conceptual instruments to promote skeptical thinking and logical analysis. Peters and Heron (1993) add that practitioners, when trying to judge the efficacy of any educational or therapeutic approach, should consider answering these five questions:

1. Does the model or program derive from a sound theoretical base?
2. Is the research methodology convincing and compelling?
3. Is there consensus with existing literature?
4. Is there evidence that outcome data are consistently produced?
5. Is there evidence of social validity?

the student, but also should consult with her supervisor to assist with her advocacy, and suggest a systematic assessment of the suggested treatments to identify the most effective approach.

When a behavior analyst makes a referral to another professional, there must never be referral fees or kick-backs. The practitioner should provide the client with a list of options, a choice of possible providers, and allow the client to make the final choice. No money, gifts, or favors should ever change hands when a referral from one professional results in a client contacting another professional.

SOCIAL MEDIA AND NEW TECHNOLOGIES

The use of social media is pervasive, with compelling evidence to show that a great majority of the world's population has access to, and frequently uses, smartphones, tablets, pads, and other electronic devices to share information and interact with others (Greenwood, Perrin, & Duggan, 2016; Pagoto et al., 2016). In effect, social media and the Internet have become the marketplace and village square of the 21st century, where social interactions flourish. Admittedly, social media present positive opportunities for sharing information and discussing issues pertaining to behavioral science (e.g., *Students of Behavior Analysis* on Facebook). Several media platforms (e.g., Facebook, Twitter) offer private areas where postings may be viewed by an individual, or a select few, who are provided specific and limited access. Thus, a practitioner might send a private message to an individual or limited group, to assist in supporting treatment goals or to help maintain treatment fidelity (e.g., sending reminders to collect data).

Moreover, new technologies provide individuals with the opportunity to view treatment sessions from remote locations, in real time, which can be useful for supervisors, parent/guardians, and behavior analysts in training.

Still, all therapeutic disciplines must come to terms with the proper way to use social media, without breaching confidentiality or falling into ethical quicksand. Unsecured transmission networks are of significant concern, and behavior analysts must be well versed in the nature and scope of the security provided to protect their communications. Even in supposedly secure social media sites, users must be cautious, since data breaches are always possible and security settings are subject to change by the service provider. Thus, client-specific information must always be masked, such that any individual discussed can never be identified by name or location (Pagoto et al., 2016). While codes of professional ethics are only recently beginning to catch up with the challenges posed by these new media, O'Leary, Miller, Olive, and Kelly (2017) have provided useful recommendations for maintaining professional ethics in an emerging social media environment (see Box 31.3). Further, Box 31.4 presents ways to avoid the pitfalls of using social media.

Helping the Client Select Outcomes and Behavior Change Targets

The recipient of behavior analysis services (or the recipient's guardian) should identify the ultimate goal(s) of the service, termed "outcomes." Outcomes must be meaningful to the individual, contextually appropriate, and achievable. The goals should focus on a quality of life issue for the individual (e.g., obtaining employment, establishing long-term relationships, accessing community and educational settings) (Felce & Emerson, 2000; Risley, 1996). The behavior analyst should help the individual express her preferences and life goals, and identify what behaviors she would need to do (and not do) to help accomplish those goals. Behaviors selected for change must benefit the individual recipient of services, not the practitioner or caregiver.

Early on, behavior analysts were rightly criticized for focusing on behaviors that mainly benefited staff (e.g., Winett &

BOX 31.3

Recommendations for Behavior Analysts' Use of Social Media

1. *Real clients should be heavily disguised.* Whenever talking about anything client specific, many details can be changed and the point of the discussion remains intact.
2. *Avoid making treatment recommendations.* There is simply not enough information on social media outlets to give specific advice.
3. *Refer readers back to the literature.* Rather than making a treatment recommendation, recommend a specific paper, or work by particular authors.
4. *Write a disclaimer.* Be sure that anyone reading anything you write, especially an answer to a question, cannot get the idea that there is a professional relationship. Be explicit in stating this.
5. *Provide resources.* Beyond literature references, provide interested parties with ideas for search topics, websites, and the opportunity to discuss a post offline, to prevent misinterpretation by non–behavior analysts.
6. *Provide organizational training.* This fits with *The Compliance Code's* requirement that we create a culture of ethics. Training in a work setting on how to navigate the dangerous currents of social media can be vital in preventing potential problems.

From "Blurred Lines: Ethical Implications of Social Media for Behavior Analysts," by P. N. O'Leary, M. M. Miller, M. L. Olive, and A. N. Kelly, 2017, *Behavior Analysis in Practice, 10*, pp. 45–51. Used with permission.

BOX 31.4

The Pitfalls of Social Media

Guy is a veteran behavior analyst who reads young BCBAs' case-related questions on a Facebook page titled "Behavior Analysis Q&A!" and provides answers and treatment advice to help guide them along. Everyone on the Facebook page tells Guy how much his help is appreciated. Even if the posted questions are carefully written so they contain no hints of client identity or specific setting, are there ethical issues involved here? Yes, many. The young practitioners might begin to rely on the sage advice provided by this "Facebook expert" and possibly others who provide quick answers. Those posing questions may, over time, become less likely to search the literature, seek necessary supervision or mentoring, or obtain consultations. They may eventually engage in the same form of "social media mentoring," since Guy has modeled this as a form of appropriate professional behavior. Any advice given on a case-related question, no matter how wise it may be, is based on incomplete information. Others reading these posts, including non–behavior analysts, might misuse these treatment suggestions by inappropriately applying them to other individuals with other behavior problems in other settings. Everything about Guy's apparently supportive action violates the core focus of our clinical approach: to directly evaluate the behavior of the individual in context, and base treatment on identified functional relations. The behavior of this seasoned adviser may help a few people, but he will almost certainly never know the extent of the damage he may well have caused.

Winkler, 1972). For example, an adult in a work setting might easily have had docile "compliance" identified as a target behavior, even though strengthening work skills and functional social interactions would have been of far greater benefit to that individual. Compliance, once commonly identified in behavior programs, is not an appropriate goal by itself. The question must be posed: compliant to what? Teaching compliance is ethically justifiable only when it facilitates the development of other functional or social skills that will, in turn, contribute to that individual's obtaining long-term self-identified outcomes.

This discussion on appropriate selection of goals, along with prior information on obtaining input from a guardian, surrogate, or advocate may be applied to the first scenario described in the opening of the chapter. Dr. Han could suggest that Lee meet with a trusted adviser or surrogate to review the pros and cons of the move from a residential program to an apartment. In addition, they could discuss the reasons Lee wants to move, to see if the current setting could be adjusted in ways that would meet his needs more effectively, without having to go through a move in residence.

Maintaining Records

Well-maintained records (e.g., assessments, treatment plans, progress notes, data) facilitate the provision of future services, meet agency and/or institutional requirements, ensure accurate billing, allow for future research, and help meet legal requirements. Behavior analysts must typically maintain all case file records for 7 years, subject to individual, state, or jurisdictional requirements. *The Compliance Code* states that the behavior analyst is responsible for maintaining individual client confidentiality in terms of "creating, storing, accessing, transferring, or disposing of records under their control, whether these are written, automated, electronic, or in any other medium" [*The Compliance Code* 2.07(a)]. When destroying paper records, use crosscut shredding. Destruction of electronic records requires that all stored files in all possible storage locations be fully expunged. Be aware that electronic transmission of confidential records across any unsecured medium (e.g., fax lines in public areas, e-mail) is prohibited under Public Law 104-191 (HIPAA).

ADVOCATING FOR THE CLIENT

Providing Necessary and Needed Services

Prior to initiating services, a behavior analyst has the responsibility to validate that a referral warrants further action. This poses the first ethical challenge to the practitioner: deciding whether to accept or reject the case. The decision to provide treatment may be divided into two sequential decisions: (1) Is the presenting problem amenable to behavioral intervention? and (2) Is the proposed intervention likely to be successful?

Is the Problem Amenable to Behavior Treatment?

To determine whether behavioral intervention is necessary and appropriate, the behavior analyst should seek answers to the following questions:

1. Has the problem emerged suddenly?
   a. Might the problem have a medical cause?
   b. Has a medical evaluation been done?
2. Is the problem with the client or with someone else? (For example, a student who has done well through fourth grade suddenly exhibits "behavior problems" in fifth grade, although she remains well behaved at home. Perhaps a simple change of teachers will solve the problem.)
3. Have other interventions been tried?

4. Does the problem actually exist? (For example, a parent has serious concerns about a 3-year-old child who "refuses to eat" everything provided at every meal.)
5. Can the problem be solved simply or informally? (For example, the same 3-year-old "elopes" through a back door that is left wide open all day.)
6. Might the problem be better addressed by another discipline? (For example, a child with cerebral palsy may need adaptive equipment instead of behavioral treatment.)
7. Is the behavioral problem considered an emergency?

Is the Proposed Intervention Likely to Be Successful?

Questions to ask when considering whether the intervention is likely to be successful include the following:

1. Is the client willing to participate?
2. Are the caregivers surrounding the client willing or able to participate?
3. Has the behavior been successfully treated in the research literature?
4. Is public support likely?
5. Does the behavior analyst have the appropriate experience to deal with the problem?
6. Will those most likely to be involved in implementing the program have adequate control of the critical environmental contingencies?

If the answer to all six of the questions posed in this second list is "yes," then the behavior analyst can act. If the answer to any of these six questions is no, the behavior analyst should seriously consider declining to initiate treatment.

Embracing the Scientific Method

General questions related to what constitutes science and how it applies to the study and improvement of behavior were addressed in Chapter 1. The scientific method relates to ethics, at least in part, in its insistence that evidence-based practices utilize direct measurement to establish the effectiveness of methods that are grounded in peer-reviewed literature, and tests any emerging practice to assess its effectiveness before implementation. The importance of embracing evidence-based practices increases as questionable claims regarding effective "alternative" treatments become more widespread, and are seemingly accepted by the general public without critical examination (Shermer, 1997). In Sagan's (1996) view, extraordinary claims require extraordinary evidence, and as space engineer James Oberg wryly quipped, "In science keeping an open mind is a virtue, but not so open that your brains fall out" (cited in Sagan, 1996, p. 187).

Applied behavior analysts should base their practice on two primary sources: scientific literature and frequent direct measurement of behavior in context. Peer-reviewed scientific reports published in reputable journals and well-referenced texts provide objective information on effective intervention strategies. Direct repeated measurement of behavior provides empirical data to inform our assessments and evaluations of the effectiveness of our work. The cornerstone of ethical practice is providing effective services based on solid, replicated research evidence.

Alternative/Fad Treatments

The educational and therapeutic world abounds in a wide variety of teaching techniques and approaches to address problem behavior. Most of these so-called remedies have never been scientifically or empirically validated. As new, untested treatments arise, parents, teachers, and other caregivers who legitimately seek educational, social, or behavioral assistance can easily fall prey to ill-advised and uninformed pied pipers (Heron et al., 2005). For example, Kohn (1997) promotes the notion that repeated practice of a skill is harmful because it destroys a student's motivation to learn, and ultimately results in the student being unhappy with school in general. This assertion has gained traction with the general public despite a complete lack of peer-reviewed evidence to validate the claim. On the contrary, decades of carefully controlled and replicated research have demonstrated that repeated practice is a key determinant in the mastery of a skill (Binder, 1996; Ericsson & Charness, 1994).

Box 31.5 explores several issues and problems related to the continuing emergence of alternative and fad treatments.

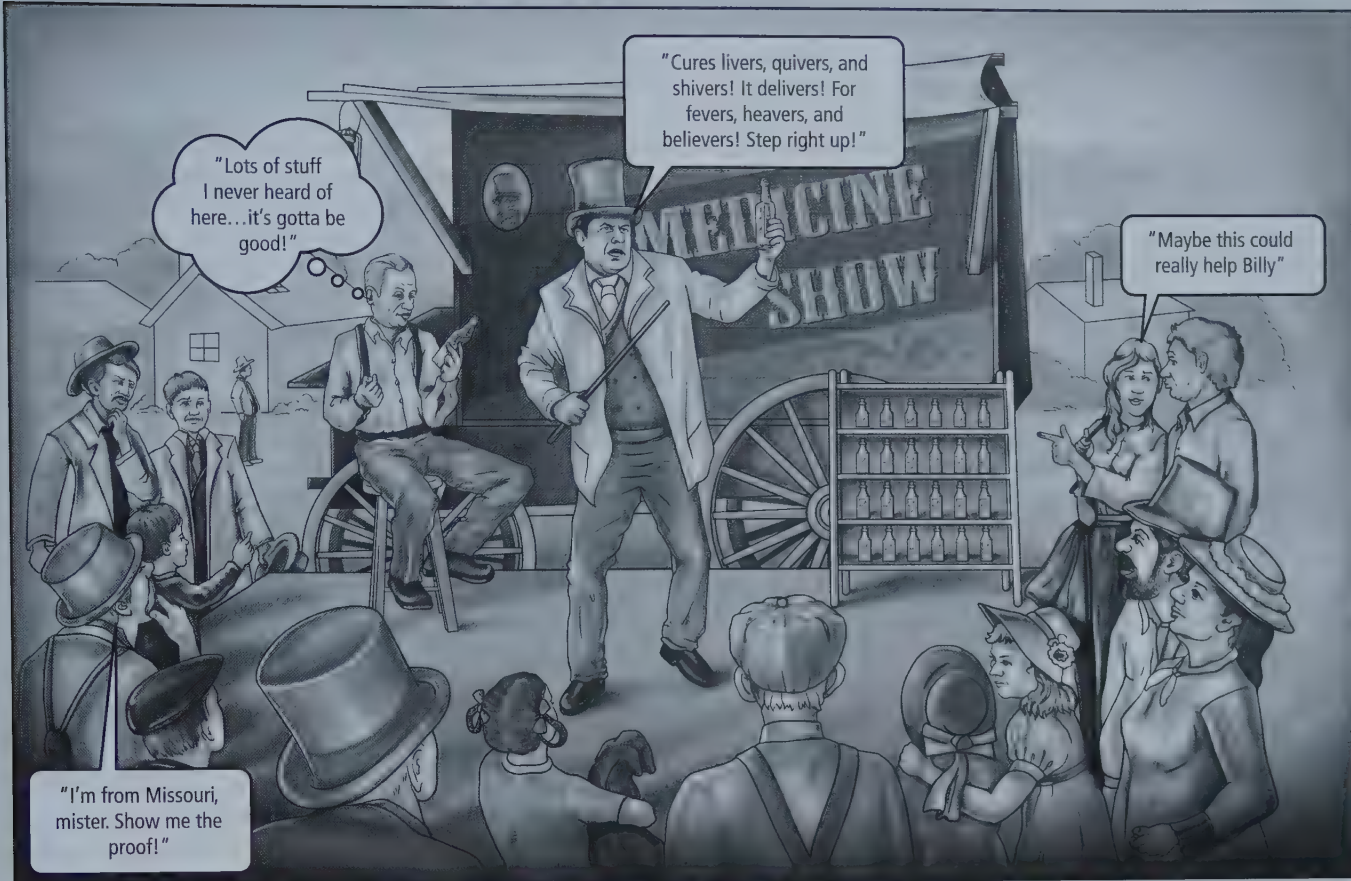
Evidenced-based Best Practice and Least Restrictive Alternatives

Silvestri and Heward (2016) define evidence as "the outcome of the application of the scientific method to test the effectiveness of a claim, a theory, or a practice." Moreover, they state that, "extraordinary evidence requires replication. A single study, anecdote, or theoretical article, no matter how impressive the findings or how complicated the writing, is not a basis for practice" and that "an extraordinary claim based on anything but proportionally strong evidence should bring skepticism" (pp. 149–150).

An essential component of ethically driven behavior analysis is not only that interventions and related practices be evidence-based, but also that the most powerful, yet least intrusive methods be used first. Moreover, intervention plans must be designed, implemented, and evaluated systematically. If the individual fails to show progress, data systems should be reviewed and, if necessary, interventions modified. If progress is made, the intervention should be phased out and assessed for generalization and maintenance. In all phases of an intervention, data and direct observations should drive treatment decisions. Models and programs that meet the above standard are deemed "best practice" and can be judged by their meeting at least five standards: Does the model or program derive from a sound theoretical base? Is the research methodology convincing and compelling? Is there consensus with existing literature? Is there evidence that outcome data are consistently produced? Is there evidence of social validity? (Peters and Heron, 1993). *The Compliance Code* [2.09(c)] also indicates that when "more than one scientifically supported treatment

BOX 31.5

Lotions, Potions, and False Notions



The promotion and sale of ineffective treatments for a variety of ailments has a long history. "Snake-oil salesmen" were so common in the Wild West era of the United States that the term is now used to label any purveyor of fake cures or, more broadly, false solutions to problems. Individuals who are likely to seek behavior analytic services have often been confronted with a dizzying array of claims and counter-claims regarding a wide variety of alternative treatment options. Many promise spectacularly positive results and even total "cures" for everything from confrontational teenage behavior to the full spectrum of autism-related disorders. Most of these claims have no solid foundation in research or peer-reviewed literature. Treatments such as *DIRFloortime*, *Doman-Delacato patterning treatment*, *aromatherapy*, *animal-assisted therapies*, and *auditory integration training* (to name but a few) lack reputable scientific evidence base (Hines, 2001; Koocher & Gill, 2016; Mudford & Cullen, 2016). Other alt-treatments have been extensively studied and soundly debunked, as in the case of *facilitated communication* (Jacobsen, Foxx, & Mulick, 2016; Lilienfeld, Marshall, Todd, & Shane, 2015). We expect other untested treatments to enter the marketplace, many likely to use new technology-based interventions that sound highly scientific but lack a firm basis in research and replication. When a behavior analyst is providing services to an individual who may be tempted to try one or more of these alt-treatments, he or she has a responsibility to assist that individual in evaluating the likely effectiveness and potential costs related to the proposed intervention.

has been established, additional factors may be considered in selecting interventions, including, but not limited to, efficiency and cost-effectiveness, risks and side-effects of the interventions, client preference, and practitioner experience and training" (2014, p. 9). Geiger, Carr, and LeBlanc (2010) describe a similar approach to selecting among function-based treatments for problem behavior, taking into account consideration of implications for safety, the resources of the environment, and prioritization of improved quality of life and skills for the client (see Figure 31.12).

Figure 31.12 Selecting function-based interventions.

Presenting Concern	Ethical Problem-solving Strategies
Background: Marco is a 3-year-old child diagnosed with autism spectrum disorder. He has very minimal verbal skills but is fortunate enough to be enrolled in an early intensive behavioral intervention program. He is making progress in developing new skills more rapidly than others. He often has tantrums with his parents, particularly when they are performing activities of daily living (e.g., dressing him) and hygiene maintenance (e.g., brushing his teeth). During these tantrums, he yells, cries, and engages in self-injurious behavior (e.g., scratching at his own arms) as well as assaultive behavior (e.g., scratching and pinching others). Marco has begun to exhibit these same behaviors with the staff who work with him in his behavioral program. His BCBA has conducted a comprehensive functional assessment, including a functional analysis. The identified function of these behaviors is escape (i.e., negative reinforcement function). The BCBA must now develop a behavior plan to reduce his problem behavior and increase his appropriate completion of tasks. This BCBA has read a number of articles from the literature and discovered that many evidence-based interventions are function-based treatments for escape-maintained problem behavior, and he is unsure which of them would be best suited to this situation.	*Analysis and Action*: Marco's BCBA identified a published clinical decision-making model for selecting function-based treatments for escape-maintained problem behavior (Geiger, Carr & LeBlanc, 2010). This model suggests that five core considerations should guide the determination of which intervention is best suited for a specific situation: Quality of life of the client, safety of everyone involved, resource constraints of the environment, existing skill sets of the client, and remaining skill needs of the client. The BCBA answered the progressive list of questions suggested in this model and determined that the optimal intervention would be functional communication training (FCT). The tasks that are occurring now are necessary and the instructional procedures are generally quite good. Marco's staff and parents felt as though they could remain safe and tolerate a small amount of problem behavior as long as it is decreasing over time. Marco will comply with several demands, and it is acceptable to allow periodic breaks from tasks as part of a treatment plan. This allowed Marco's BCBA to consider the most important skill to prioritize. Since Marco has very limited verbal skills, it is important to teach him a way to ask for a break or assistance when he finds himself in an aversive situation. So FCT is a great first intervention, and other interventions might be added if needed.

CONFLICT OF INTEREST

A **conflict of interest** occurs when a principal party, alone or in connection with family, friends, or associates, has a vested interest in the outcome of the interaction. The most common form of conflict arises in the form of dual- or multiple-role relationships. Conflicts arise when a person acting as a therapist enters into another type of relationship with the client, a family member, or a close associate of the client, or promises to enter into such a relationship in the future. These relationships may be financial, personal, professional (providing another service, for example), or otherwise beneficial to the therapist.

Direct and frequent observations during assessment and intervention phases bring the behavior analyst into close contact with the client (and often family members, other professionals, and caregivers) in various natural settings. Personal relationships can be formed that may imperceptibly cross professional boundaries. For example, family members may offer unsolicited gifts or make invitations to parties or other events. In every interaction related to their professional duties, behavior analysts must monitor their own behavior with vigilance, guarding against blurring the lines between personal and professional conduct. This is especially true when treatment is provided within a private home. In service contexts, personal relationships of any kind can quickly develop ethical complications, and are to be avoided.

Other professional conflicts of interest might arise as well. For example, a teacher should never hire a current student as an employee in a business outside of school. That student's performance in one area could potentially affect the teacher–student interaction in the other. A supervisee should be off limits as a potential romantic partner. A member of a peer review committee must not participate in a review of his own work, or the work of his supervisees. The general rule to follow is that the practitioner should strive to avoid all potential conflicts of interest. A practitioner in doubt should consult with a supervisor or trusted and experienced confidant.

CREATING A CULTURE OF ETHICAL PRACTICE

Ethical or unethical behavior occurs in an environmental context, and environments can be arranged to support behavior that is ethical. Moreover, "the ability to sort through the issues and make decisions that most people would see as ethical is a skill that emphatically can and should be taught" (Lattal & Clark, 2007, p.13). Even the most proficient professionals benefit from robust environmental supports for problem-solving repertoires that help maintain ongoing ethical practice. To foster a culture of ethical practice (*The Compliance Code* 7.01), organizations can commit to providing ethics-related trainings, support systems, and differential reinforcement of ethical behavior. Brodhead and Higbee (2012) outline various strategies for teaching and maintaining ethical behavior in a professional organization. They address the importance of initial training in ethics and ongoing training and supervision

BOX 31.6

Does Your ABA Organization Have an Ethics Director?

The Ethics Network at Linda LeBlanc's clinical service organization includes a position of Ethics Director. This doctoral-level behavior analyst has extensive experience as a supervisor and extensive training in ethics. The Ethics Director serves as a mentor to the ethics and assistant ethics chairpersons, each of whom fosters and supports ethics throughout the organization. The Ethics Network engages in four primary activities designed to sustain continuous discussion about ethics at all levels of the organization.

First, the network director designed the initial ethics training for all members of the organization with a focus on (1) core principles that underlie all aspects of our ethical code and (2) structured practice in a six-step problem-solving process that includes detection and (3) an analysis of situations as potential ethical dilemmas.

Second, the network director monitors an internal ethics hotline that can be accessed by any member of the organization who needs support with a difficult or ambiguous situation. Asking for assistance through this mechanism is differentially reinforced with swift assistance and praise for critical analysis of the situation, as prompted by the submission portal (i.e., the problem-solving steps). The ethics leadership team analyzes topics and situations submitted to the hotline to hone team members' skills in responding to ethical conundrums. Those situations are used monthly to create instructional materials called "discussion starters"; these include specific role plays that can be used in supervision activities throughout the organization.

Third, semi-annual trainings occur with the clinical team to review material that is pertinent to the most challenging situations submitted to the hotline (e.g., ethical issues associated with serving families who are experiencing divorce or separation).

Fourth, the ethics network director leads discussions with the administrative leaders of the organization at least annually to focus on specific parts of *The Compliance Code* that are directly pertinent to their ongoing activities (e.g., review of codes relevant to social media and nonsolicitation of testimonials with the marketing team). Since these individuals generally have very different training and backgrounds than behavior analysts, they may be likely to misrepresent important features of our code and our field unless the behavior analyst accepts the responsibility to educate them about the underlying principles that lead us to value certain actions (Code 10.07).

Establishing the Ethics Network has been personally and professionally rewarding, as it has led to improved communication, enhanced problem solving, team collaboration, and higher quality service to our clients.

that directly incorporates ethics as a professional development topic. In addition, they recommend using previous ethically complex situations as instructional opportunities to prevent recurrence of the same problem.

In sum, continuous education and discussion about ethics and the contingencies that support analysis and assistance seeking are core features of an environment designed to maintain ethical behavior in an organization (see Box 31.6). When individual behavior analysts do not operate within an environment with other behavior analysts, they should initiate connections with other behavior analysts through professional organizations, conference sessions, or seminars to access support and consultation as needed.

CONCLUSION

Practicing ethically poses daily challenges. It requires vigilance, self-monitoring, and the ongoing dynamic application of one's principles and professional code. Our profession has created a code of ethical conduct and set consequences for violating those rules. But we can also create cultures of ethics in a wide variety of settings, to help train practitioners in ethical decision making and to support ongoing discussion of ethical issues. In this way, we take an antecedent approach that promotes ethical action and effectively prepares the behavior analyst for acting ethically at the moment when an ethical dilemma presents itself, the moment when unethical behavior is most likely to occur.

Most ethical challenges, regardless of the details involved, may best be addressed by revisiting the three questions posed early in the chapter: What is the right thing to do? What is worth doing? What does it mean to be a good behavior analyst? These three questions can serve as focal points for effective and ethical decision making. Addressing these questions honestly and without bias will help practitioners avoid many potential ethical pitfalls and keep their efforts centered on the interests of the client, the student, or others receiving their services.

By practicing ethically, and by maintaining adherence to the scientific method and the principles, procedures, and dimensions of applied behavior analysis, practitioners have a ready source of valid, accurate, reliable, and believable data to inform decision making. As a result, they will be more likely to achieve the original and continuing promise of applied behavior analysis: to apply knowledge gained through research in both the experimental analysis of behavior and applied behavior analysis to help solve problems of social importance to each individual recipient of services.

SUMMARY

What Is Ethics and Why Is It Important?

1. For the applied behavior analyst, ethics defines specific rules of conduct.
2. Two approaches to ethics are termed the *deontological* or *"acts-oriented" approach*, which evaluates only the act itself, and the *utilitarian* or *"results-oriented" approach*, which looks at the results or consequences of the act. Both approaches contribute to the ethical conduct of behavior analysts.
3. Ethics describes behaviors, practices, and decisions that address three basic and fundamental questions: What is the right thing to do? What is worth doing? What does it mean to be a good behavior analyst?
4. Ethics is important because it helps practitioners decide whether a course of action related to the professional practice of behavior analysis is appropriate or inappropriate. Codes of ethics guide decisions on how to act even in the presence of outside pressures, priorities, or expediencies.
5. Ethical practices are derived from other behavior analysts and professionals to ensure the well-being of (a) clients, (b) the profession itself, and (c) the culture as a whole. Over time, practices become codified into ethical rules of conduct that may change in response to a changing world.
6. Personal histories, including cultural and religious experiences, influence how practitioners decide on a course of action in any given situation.
7. Practicing behavior analysts must be aware of the settings in which they work and the specific rules and ethical standards applicable to those settings. Behavior analysts are required to be fully familiar with all ethical and legal issues pertaining to their practice.

Standards of Professional Practice for Applied Behavior Analysts

8. Professional organizations adopt formalized statements of conduct, codes of professional behavior, or ethical standards of behavior to guide their members in making decisions. Also, standards exact sanctions when deviations from *The Compliance Code* occur.
9. The client's welfare is at the forefront of ethical decision making.
10. Behavior analysts must take steps to ensure that their professional conduct is self-regulating.
11. Professional standards, guidelines, or rules of practice are written statements that provide direction for conducting the practices associated with an organization.
12. Behavior analysts are guided by position statements and ethical codes such as the *Professional and Ethical Compliance Codes for Behavior Analysts, Ethical Principles of Psychologists and Code of Conduct, The Right to Effective Behavioral Treatment, Statement on Restraint and Seclusion*, and *The Right to Effective Education.*
13. Behavior analysts are now held to *The Compliance Code*, and perceived violations of that code can be reported using a notice of alleged violation.

Ensuring Professional Competence

14. Professional competence in applied behavior analysis is achieved through formal academic training that involves coursework, supervised practica, and mentored professional experience.
15. Behavior analysts must be truthful and accurate in all professional and personal interactions.
16. Competence in supervision is critical, as most behavior analysts supervise the work of others in the context of their practice.
17. Formal certification and/or licensure credentials in behavior analysis allow consumers to identify practitioners who have demonstrated at least a minimum standard of training and competence.
18. Behavior analysts must practice within their areas of competence, training, and experience.
19. Behavior analysts can develop additional competencies through supervised or mentored experience.
20. Behavior analysts take responsibility for all facets of the undertaking when providing supervision and/or mentoring of other behavior analysts, individuals seeking certification in behavior analysis, paraprofessionals, or non–behavior analysts.
21. Behavior analysts have a responsibility to maintain and expand professional competencies, and may do so using continuing education, participation in professional conferences, maintaining contact with current professional literature, and/or participating in peer review committees.

Ethical Issues in Client Services

22. Three tests must be met before informed consent can be considered valid: capacity to decide, voluntary decision, and knowledge of the treatment.
23. Confidentiality refers to the professional standard requiring that the behavior analyst not discuss or otherwise release information regarding someone in his or her care. Information may be released only with formal permission of the individual or the individual's guardian.

24. Practicing behavior analysts have a responsibility to protect a client's dignity, health, and safety. Various rights must be observed and protected, including the right to make choices, the right to privacy, the right to a therapeutic treatment environment, and the right to refuse treatment.

25. Negligence (not doing what one should) and fraudulent conduct (willful deceit likely to cause harm) on the part of the behavior analyst pose a direct threat to the client's health and safety, and can result in professional sanctions and possibly legal penalties.

Coordinating with Other Professionals

26. Behavior analysts must coordinate services with other professionals in a way that best meets the interests of the individuals receiving services, and that represents the field of behavior analysis in a positive and professional manner.

27. Effective coordination between disciplines can only occur if communication among all treatment team members remains clear and frequent.

28. The best interests of the client will be served when the behavior analyst guides collaboration with other professionals in a way that enhances client services, and reflects well on the field.

Social Media and New Technologies

29. The use of social media and the emergence of other new technologies present an increasing array of opportunities, challenges, and potential ethical pitfalls for the behavior analyst. Special care must be taken to protect client confidentiality, and the behavior analyst should avoid making case-specific treatment recommendations in a public forum.

30. New technologies allow practitioners to view treatment sessions from remote locations, in real time, which can be useful for supervisors, parents/guardians, and behavior analysts in training.

31. All therapeutic disciplines must come to terms with the proper way to use social media, without breaching confidentiality or ethical guidelines.

32. The individual receiving services must be given the opportunity to assist in selecting and approving treatment goals. Outcomes must be selected that are primarily aimed at benefiting the individual receiving services.

Advocating for the Client

33. In deciding to provide services, the behavior analyst must determine that services are needed, that medical causes have been ruled out, that the treatment environment will support service delivery, and that a reasonable expectation of success exists.

34. The choice to provide treatment may be divided into two sets of decision rules: (1) determining that the problem is amenable to behavioral intervention and (2) evaluating the likely success of an intervention.

35. The behavior analyst should advocate for the most effective, scientifically supported treatment procedures. The behavior analyst must also take into account the social validity of any proposed treatment procedures. The behavior analyst has the responsibility to objectively evaluate alternative treatments when necessary and appropriate.

36. Behavior analysts embrace the scientific method, and promote evidence-based practices in all consumer-related services.

Conflict of Interest

37. A conflict of interest occurs when a principal party, alone or in connection with family, friends, or associates, has a vested interest in the outcome of the interaction.

38. All sources of conflict of interest, particularly dual relationships, are to be avoided.

Creating a Culture of Ethical Practice

39. When coordinating with other professional service providers, behavior analysts have a responsibility to review and appraise the effects of any treatments that might affect the goals of the behavior change program.

40. To foster a culture of ethical practice, organizations can commit to providing ethics-related trainings, support systems, and differential reinforcement of ethical behaviors.

41. Continuous education and discussion about ethics and the contingencies that support analysis and assistance seeking are core features of an environment designed to maintain ethical behavior in an organization.

ethics
informed consent

MULTIPLE-CHOICE QUESTIONS

1. When trying to determine the right thing to do in a given situation, which factors should you consider?
   - **a.** Your own personal history in similar circumstances
   - **b.** Your professional training and experience
   - **c.** The rules of the local setting
   - **d.** Ethical guidelines published by your professional organization
   - **e.** All of these

   Hint: (See "What Is Ethics and Why Is It Important?")

2. "Ethics" encompasses:
   - **a.** The primary goal is of furthering the welfare of the client
   - **b.** Behaviors and decisions that revolve around the "right thing to do"
   - **c.** Following the rules of professional codes and standards
   - **d.** What is morally right
   - **e.** All of these

   Hint: (See "What Is Ethics and Why Is It Important?")

3. Which of the following organizations does not have ethical guidelines, standards, or position statements that behavior analysts should follow, according to your text?
   - **a.** American Psychological Association
   - **b.** Association for Behavior Analysis
   - **c.** Association for Direct Instruction
   - **d.** Behavior Analyst Certification Board

   Hint: (See "Standards of Professional Practice for Applied Behavior Analysts")

4. Which of the following is not a right to effective education, as delineated by the Association for Behavior Analysis in 1990?
   - **a.** Social and physical school environments that encourage and maintain academic achievement and progress
   - **b.** Curriculum and objectives based on empirically validated hierarchies or sequences of instructional objectives
   - **c.** Financial consequences for the school and its performance are based on subjective measures by the school board
   - **d.** Specific mastery criteria that include both the accuracy and speed dimensions of fluent performance

   Hint: (See "Standards of Professional Practice for Applied Behavior Analysts")

5. Which of these does not help individuals gain professional competence in their field?
   - **a.** Formal coursework
   - **b.** Supervised practica
   - **c.** Mentored professional experience
   - **d.** Attending nonaccredited workshops and training
   - **e.** Successfully completing accredited university training programs

   Hint: (See "Ensuring Professional Competence")

6. What should you do if you are in a situation where the demands of the situation exceed your training?
   - **a.** Reassure the clients that you are a qualified behavior analyst and continue with the intervention you have in place.
   - **b.** Tell the clients that you are not qualified to provide treatment and walk away.
   - **c.** Seek additional training in the area of competence so as to improve your skills.
   - **d.** Make a referral to another behavior analyst or consultant.
   - **e.** The third and fourth answer choices are correct.

   Hint: (See "Ensuring Professional Competence")

7. Joan is a behavior analyst providing services to a child with autism. She has been having a difficult time with the child's family. She is out for coffee one day, when her cell phone rings. It is her mother, who asks how things are going. She tells her mother about her woes with this family, explaining that the intervention she has implemented doesn't seem to be working and that she is having trouble with the parents, who seem to be questioning her skills. Her mother, who is a retired teacher (not a behavior analyst), asks, "Is this the same family that you had trouble with last year?" Joan replies, "No, this is a different family. This is the Jacksons. They are very wealthy and live on the upper side of town. You remember them. You met them at a school board meeting once." Consider Joan's behavior relative to issues of confidentiality. Which of the following statements is true?
   - **a.** Joan committed a breach of confidentiality unintentionally, so this breech of confidentiality is not of concern.
   - **b.** Joan committed a breach of confidentiality intentionally, and this is of great concern.
   - **c.** Joan committed a breach of confidentiality intentionally, but it is not of great concern because her goal was to serve the greater good and avoid future problems for this child.
   - **d.** No breach of confidentiality occurred because Joan did not give out any personally identifiable information.

   Hint: (See "Ethical Issues in Client Services")

8. Michael is a behavior analyst working at an adult day treatment program, where the staff always involves their clients in planning their day programs. Today, Michael is holding a meeting with one of his clients, Dan, who has moderate mental disabilities and has been having trouble with his behavior during work periods. Dan has been getting up partway through the day and running out of the room, screaming. While he is out of the room, he often tears papers off the wall and destroys the agency's property. The team is meeting with Dan today to determine how his intervention will be revised. Michael is proposing that a response cost intervention be imposed, where Dan will lose some of the money he has earned for every minute

he is out of the room. Dan is opposed to this intervention because he doesn't want to be fined. Michael and the team say to Dan, "But this intervention is trying to help you. I guess if you don't want to do this, we will have to revise your intervention so that you don't earn as much money. We need to pay for all the damage you have caused." After discussing some other options that the team didn't feel would be as effective, Dan says he'd like to think about it, but his bus just pulled up and he needs to leave for the day. The team tells him this needs to be decided today, or he cannot return to the facility tomorrow. What ethical issue has the team violated?

a. They have implemented intervention and assessment without Dan's consent.

b. They are attempting to coerce Dan into the intervention, interfering with his right to voluntarily participate in the intervention.

c. They have breeched confidentiality by sharing this information with Dan and staff.

d. Michael has not shared all of the relevant treatment information with Dan so that he can make an informed decision.

Hint: (See "Ethical Issues in Client Services")

9. Which of these are important considerations in deciding whether or not an intervention is likely to be successful?

a. Is the client willing to participate?

b. Has the behavior been successfully treated in the research literature?

c. Is public support likely?

d. Will those involved in the treatment have control over the critical contingencies?

e. All of these

Hint: (See "Advocating for the Client")

10. What is a conflict of interest?

a. When a behavior analyst, either alone or in tandem with a client, family, friends or associates of the client has a vested interest in the outcome of the interaction.

b. When all members of a team have a similar treatment goal for an individual.

c. When one member of a team has a negative history with the behavior analyst and the two do not get along well.

d. When parents hire a behavior analyst to consult with their child and to provide recommendations to a local school.

Hint: (See "Advocating for the Client")

ESSAY-TYPE QUESTIONS

1. Why are ethics important? Specifically, what do ethical principles do to help guide the practitioner?

Hint: (See "What Is Ethics and Why Is It Important?")

2. Explain the role of professional organizations in creating and enforcing professional ethical codes.

Hint: (See "Standards of Professional Practice for Applied Behavior Analysts")

3. Give an example of individuals practicing within their area of competence and an example of persons practicing outside their area of competence.

Hint: (See "Ensuring Professional Competence")

4. Give an example of a situation where you might provide treatment without consent from either an individual or a guardian.

Hint: (See "Ethical Issues in Client Services")

5. Prior to initiating treatment, the behavior analyst must take into account a number of important considerations. List those considerations.

Hint: (See "Advocating for the Client")

NOTES

1. The Behavior Analyst Certification Board's (BACB's) Professional and Ethical Compliance Code for Behavior Analysts (the "Code") consolidates, updates, and replaces the BACB's Professional Disciplinary and Ethical Standards and Guidelines for Responsible Conduct for Behavior Analysts. *The Compliance Code* includes 10 sections relevant to professional and ethical behavior of behavior analysts, along with a glossary of terms. Effective January 1, 2016, all BACB applicants, certificants, and registrants will be required to adhere to *The Compliance Code*. Source: www.BACB.com.
2. For a list of colleges and universities with graduate programs in behavior analysis, see the *ABAI's Behavior Analysis Training Directory* [https://www.abainternational.org/constituents/educators/training-directory.aspx].
3. Information on the BACB's certification requirements and process is available at: www.BACB.com.
4. Readers interested in early literature on risk–benefit analysis should see Spreat (1982) and Axelrod, Spreat, Berry, & Moyer (1993).

Epilogue

From its earliest days, the story of applied behavior analysis has been one of continuous advancements in understanding how behavior works and how to change it for the better. Today's behavior analysts help more people learn new skills, achieve performance goals, and replace problem behaviors with healthy alternatives in a wider range of settings and circumstances than ever before. We are confident tomorrow's behavior analysts will be even more skillful and effective in improving the quality of people's lives.

Some of you will earn advanced degrees in behavior analysis. Your research, writing, and teaching will expand the knowledge base and practice of the science. Many of you will become professionals whose practice is informed by applied behavior analysis. Your skillful and ethical use of behavioral interventions will enhance the quality of the lives you touch. We hope all of you will bring what you have learned about behavior to your everyday lives.

We cannot express our perspective on the potential of, and necessity for, applied behavior analysis to contribute to a healthier and happier human experience more eloquently than did Ellen Reese (1966) more than 50 years ago:

> The pertinent question is how to use our increasing knowledge of behavior to best advantage. . . . It is a question that concerns all of us, as all of us exercise control over our families and friends, and all of us delegate control to professionals in education, government, and law. We can close our eyes to the techniques of behavior control and risk everything, or we can use these techniques effectively to create the kind of world we want to live in. The latter course requires that we keep informed. Fortunately, the science of behavior is neither esoteric nor obscure. It is a young science, an exciting one, and an important one; for surely a proper study of mankind is his behavior. (p. 63)

Applied behavior analysis is still a young, exciting, and vital science. Given humanity's current challenges, its potential for good is more important than ever before.

Thank you for reading our book. We hope you will continue learning about applied behavior analysis and use your growing knowledge to help make the world a better place. These endeavors are worthy of your talent, time, and effort.

GLOSSARY

A

A-B design A two-phase experimental design consisting of a pretreatment baseline condition (A) followed by a treatment condition (B).

A-B-A design A three-phase experimental design consisting of an initial baseline phase (A) until steady state responding (or counter-therapeutic trend) is obtained, an intervention phase in which the treatment condition (B) is implemented until the behavior has changed and steady state responding is obtained, and a return to baseline conditions (A) by withdrawing the independent variable to see whether responding "reverses" to levels observed in the initial baseline phase. (See also **A-B-A-B design, reversal design,** and **withdrawal design.**)

A-B-A-B design An experimental design consisting of (1) an initial baseline phase (A) until steady state responding (or counter-therapeutic trend) is obtained, (2) an initial intervention phase in which the treatment variable (B) is implemented until the behavior has changed and steady state responding is obtained, (3) a return to baseline conditions (A) by withdrawing the independent variable to see whether responding "reverses" to levels observed in the initial baseline phase, and (4) a second intervention phase (B) to see whether initial treatment effects are replicated. (Also called *reversal design* and *withdrawal design.*)

abative effect (of a motivating operation) A decrease in the current frequency of behavior that has been reinforced by some stimulus, object, or event whose reinforcing effectiveness depends on the same motivating operation. For example, food ingestion abates (decreases the current frequency of) behavior such as opening the fridge that has been reinforced by food.

ABC recording See **anecdotal observation.**

abolishing operation (AO) A motivating operation that decreases the reinforcing effectiveness of a stimulus, object, or event. For example, the reinforcing effectiveness of food is abolished as a result of food ingestion.

acceptance and commitment therapy (ACT) An evidence-based behavior therapy focusing on general well-being, defined as making reliable contact with high-priority positive reinforcers.

accuracy (of measurement) The extent to which observed values, the data produced by measuring an event, match the true state, or true values, of the event as it exists in nature. (See also **observed value** and **true value.**)

adapted alternating treatments design A variation of the multielement design for comparing the efficiency of instructional procedures. The comparison phase of the design features the alternating application of two (usually) or more different teaching methods, each method applied to different but equivalent sets of instructional items. All items are topographically different members of the same response or skill class, such as reading printed words, defining vocabulary terms, spelling words, answering math problems, and stating history facts.

add-in component analysis A method for conducting a component analysis in which components are assessed individually or in combination before the complete treatment package is presented. The add-in method can identify sufficient components. Sequence and floor or ceiling effects may mask the effects of components added in toward the end of the analysis.

adjunctive behavior Behavior that occurs as a collateral effect of a schedule of periodic reinforcement for other behavior; time-filling or interim activities (e.g., doodling, idle talking, smoking, drinking) that are induced by schedules of reinforcement during times when reinforcement is unlikely to be delivered. (Also called *schedule-induced behavior*.)

affirmation of the consequent A three-step form of reasoning that begins with a true antecedent–consequent (if-A-then-B) statement and proceeds as follows: (1) If A is true, then B is true; (2) B is found to be true; (3) therefore, A is true. Although other factors could be responsible for the truthfulness of A, a sound experiment affirms several if-A-then-B possibilities, each one reducing the likelihood of factors other than the independent variable being responsible for the observed changes in behavior.

alternating treatments design See **multielement design.**

alternative schedule (alt) Provides reinforcement when the response requirements of any of two or more simultaneously available component schedules are met.

anecdotal observation A form of direct, continuous observation in which the observer records a descriptive, temporally sequenced account of all behavior(s) of interest and the antecedent conditions and consequences for those behaviors as those events occur in the client's natural environment. (Also called *ABC recording*.)

antecedent An environmental condition or stimulus change existing or occurring prior to a behavior of interest.

antecedent exercise An antecedent intervention, implemented independently of occurrences of the problem behavior, that usually has clients engage in some effortful form of aerobic activity (e.g., walking, jogging, dancing, calisthenics, roller skating). Applied behavior analysts have used antecedent exercise in the treatment of many maladaptive behaviors such as self-injurious behavior (SIB), aggression, and diverse behaviors such as inappropriate vocalizations, repetitive movements, talking-out, out-of-seat, and stereotypic behaviors.

antecedent intervention A behavior change strategy that manipulates antecedent stimuli based on (a) motivating operations (evocative and abative effects), (b) stimulus control (differential availability of reinforcement), and (c) contingency-independent interventions (e.g., protective equipment, and restraint). (See also **functional communication training, high-probability request sequence,** and **noncontingent reinforcement.** Contrast with **antecedent control,** a behavior change intervention that manipulates contingency-dependent consequence events to affect stimulus control.)

antecedent stimulus class A set of stimuli that share a common relationship. All stimuli in an antecedent stimulus class evoke the same operant behavior, or elicit the same respondent behavior. (See also **arbitrary stimulus class** and **feature stimulus class.**)

applied behavior analysis (ABA) The science in which tactics derived from the principles of behavior are applied to improve socially significant behavior and experimentation is used to identify the variables responsible for the improvement in behavior.

arbitrarily applicable relational responding (AARR) Forming new stimulus classes with little or no reinforced practice.

arbitrary relations Stimuli to which people respond in interlocked ways, not because of physical similarity, but because social-verbal reinforcement contingencies teach people to respond to them in this way.

arbitrary stimulus class Antecedent stimuli that evoke the same response but do not resemble each other in physical form or share a relational aspect such as bigger or under (e.g., peanuts, cheese, coconut milk, and chicken breasts are members of an arbitrary stimulus class if they evoke the response "sources of protein"). (Compare to **feature stimulus class.**)

artifact An outcome or result that appears to exist because of the way it is measured but in fact does not correspond to what actually occurred.

ascending baseline A data path that shows an increasing trend in the response measure over time. (Compare to **descending baseline.**)

audience Anyone who functions as a discriminative stimulus evoking verbal behavior. Different audiences may control different verbal behavior about the same topic because of a differential reinforcement history. Teens may describe the same event in different ways when talking to peers versus parents.

autoclitic The autoclitic relation involves two interlocking levels of verbal behavior emitted in one utterance. One level is a primary response (e.g., "The ice is solid"), while the other type is the secondary autoclitic response (e.g., adding "I think"). Autoclitic behavior benefits the listener by providing additional information regarding the primary response.

autoclitic frame Provide structure among verbal operants in terms of order, agreement, grouping, and composition of larger units of verbal behavior such as sentences (see Palmer, 2016). Autoclitic frames help speakers generate novel

utterances. For example, experience with the frame "the girl's (ball, dog, coat) may enable a child to say "the girl's hat" without prior teaching.

autoclitic mand An autoclitic mand involves supplemental control by an MO related to some aspect of the speaker's primary verbal response. The autoclitic mand (e.g., "Believe me, they are wrong.") enjoins a listener to take some specific action regarding the primary response, and the autoclitic behavior is reinforced by that action.

autoclitic tact An autoclitic tact is controlled by some nonverbal feature of the primary response or its controlling variables, and the autoclitic response informs the listener of that feature. This behavior is reinforced by listeners who provide generalized reinforcement.

automatic contingencies Skinner (1957) used "automatic" to identify circumstances in which behavior is evoked, shaped, maintained, or weakened by environmental variables occurring without direct manipulation by other people. All behavioral principles (e.g., reinforcement, extinction, punishment) can affect our behavior automatically.

automatic punishment Punishment that occurs independent of the social mediation by others (i.e., a response product serves as a punisher independent of the social environment).

automatic reinforcement Reinforcement that occurs independent of the social mediation of others (e.g., scratching an insect bite relieves the itch).

automaticity (of reinforcement) Refers to the fact that behavior is modified by its consequences irrespective of the person's awareness; a person does not have to recognize or verbalize the relation between her behavior and a reinforcing consequence, or even know that a consequence has occurred, for reinforcement to "work." (Contrast with **automatic reinforcement.**)

aversive stimulus In general, an unpleasant or noxious stimulus; more technically, a stimulus change or condition that functions (a) to evoke a behavior that has terminated it in the past, (b) as a punisher when presented following behavior, and/or (c) as a reinforcer when withdrawn following behavior.

avoidance contingency A contingency in which a response prevents or postpones the presentation of a stimulus. (Compare to **escape contingency.**)

B

B-A-B design A three-phase experimental design that begins with the treatment condition. After steady state responding has been obtained during the initial treatment phase (B), the treatment variable is withdrawn (A) to see whether responding changes in the absence of the independent variable. The treatment variable is then reintroduced (B) in an attempt to recapture the level of responding obtained during the first treatment phase.

backup reinforcers Preferred items, activities, or privileges that participants obtain by exchanging earned tokens in a token economy.

backward chaining A teaching procedure in which a trainer completes all but the last behavior in a chain, which is performed by the learner, who then receives reinforcement for completing the chain. When the learner shows competence in performing the final step in the chain, the trainer performs all but the last two behaviors in the chain, the learner emits the final two steps to complete the chain, and reinforcement is delivered. This sequence is continued until the learner completes the entire chain independently.

backward chaining with leaps ahead A backward chaining procedure in which some steps in the task analysis are skipped; used to increase the efficiency of teaching long behavior chains when there is evidence that the skipped steps are in the learner's repertoire.

bar graph A simple and versatile graphic format for summarizing behavioral data; shares most of the line graph's features except that it does not have distinct data points representing successive response measures through time. (Also called a *histogram*.)

baseline A condition of an experiment in which the independent variable is not present; data obtained during baseline are the basis for determining the effects of the independent variable; a control condition that does not necessarily mean the absence of instruction or treatment, only the absence of a specific independent variable of experimental interest.

baseline logic A term sometimes used to refer to the experimental reasoning inherent in single-subject experimental designs; entails three elements: prediction, verification, and replication. (See also **steady state strategy.**)

behavior That portion of an organism's interaction with its environment that involves movement of some part of the organism (Johnston & Pennypacker, 2009, p. 31). (See also **operant behavior, respondent behavior, response,** and **response class.**)

Behavior Analyst Certification Board's (BACB's) Professional and Ethical Compliance Code for Behavior Analysts Consolidates, updates, and replaces the BACB's Professional Disciplinary and Ethical Standards and Guidelines for Responsible Conduct for Behavior Analysts. *The Compliance Code* includes 10 sections relevant to professional and ethical behavior of behavior analysts, along with a glossary of terms. Effective January 1, 2016, all BACB applicants, certificants, and registrants will be required to adhere to *The Compliance Code*.

behavior chain A sequence of responses in which each response produces a stimulus change that functions as conditioned reinforcement for that response and as a discriminative stimulus for the next response in the chain; reinforcement for the last response in a chain maintains the reinforcing effectiveness of the stimulus changes produced by all previous responses in the chain.

behavior chain interruption strategy An intervention that relies on the participant's skill to initially perform all the critical elements of a chain independently, but the chain is then interrupted, or a link in the chain is made unavailable at a predetermined time, so that another behavior can be prompted or emitted.

behavior chain with a limited hold A contingency that specifies a time interval by which a behavior chain must be completed for reinforcement to be delivered.

behavior change tactic A technologically consistent method for changing behavior derived from one or more principles of behavior (e.g., response cost is derived from the principle of negative punishment); possesses sufficient generality across subjects, settings, and/or behaviors to warrant its codification and dissemination.

behavior checklist An itemized list that provides descriptions of specific skills (usually in hierarchical order) and the conditions under which each skill should be observed. Some checklists are designed to assess one particular behavior or skill area. Others address multiple behaviors or skill areas. Most use a Likert scale to rate responses.

behavior trap An interrelated community of contingencies of reinforcement that can be especially powerful, producing substantial and long-lasting behavior changes. Effective behavior traps share four essential features: (a) They are "baited" with virtually irresistible reinforcers that "lure" the student to the trap; (b) only a low-effort response already in the student's repertoire is necessary to enter the trap; (c) once inside the trap, interrelated contingencies of reinforcement motivate the student to acquire, extend, and maintain targeted academic and/or social skills; and (d) they can remain effective for a long time because students show few, if any, satiation effects.

behavior-altering effect (of a motivating operation) Either (a) an increase in the current frequency of behavior that has been reinforced by some stimulus, object, or event, called an evocative effect; or (b) a decrease in the current frequency of behavior that has been reinforced by some stimulus, object, or event, called an abative effect. For example, the current frequency of behavior that has been reinforced with food, such as opening the fridge, is evoked (increased) or abated (decreased) by food deprivation or food ingestion, respectively.

behavioral assessment A form of assessment that includes indirect and direct procedures such as interviews, checklists, and tests to identify and define the specific target behavior. In addition to identifying behavior(s) to change, comprehensive behavioral assessment can uncover functional relations between variables; it provides context on the resources, assets, significant others, competing contingencies, maintenance and generalization factors, and reinforcers (or punishers) that can be combined to improve the efficiency of an intervention.

behavioral contract See **contingency contract.**

behavioral contrast The phenomenon in which a change in one component of a multiple schedule that increases or decreases the rate of responding on that

component is accompanied by a change in the response rate in the opposite direction on the other, unaltered component of the schedule.

behavioral cusp A behavior that has sudden and dramatic consequences that extend well beyond the idiosyncratic change itself because it exposes the person to new environments, reinforcers, contingencies, responses, and stimulus controls. (See also **pivotal behavior.**)

behavioral inflexibility An insensitivity to external stimuli occurring when private events interfere with well-being behaviors on which high-priority positive reinforcers are contingent.

behavioral momentum Describes the resistance to change in a behavior's rate of responding following an alteration in reinforcement conditions. The momentum metaphor has also been used to describe the effects produced by the **high-probability (high-*p*) request sequence.**

behaviorism The philosophy of a science of behavior; there are various forms of behaviorism. (See also **methodological behaviorism** and **radical behaviorism.**)

believability The extent to which the researcher convinces herself and others that the data are trustworthy and deserve interpretation. Measures of interobserver agreement (IOA) are the most often used index of believability in applied behavior analysis. (See also **interobserver agreement [IOA].**)

bidirectional naming (BiN) A higher-order verbal cusp consisting of the fusing together of the speaker and listener repertoires in bidirectional relations (Horne & Lowe, 1996). A new word acquired as listener can generate a tact without further training, and a new word acquired as a tact can generate a listener relation without further training (these effects are consistent with emergent symmetry and mutual entailment).

bonus response cost A procedure for implementing response cost in which the person is provided a reservoir of reinforcers that are removed in predetermined amounts contingent on the occurrence of the target behavior.

brief functional analysis An analysis in which only one or two 5- to 10-min sessions are conducted for each condition. A convincing demonstration of function may be achieved by either alternating a condition that produces problem behavior with one that does not or conducting a contingency reversal. Brief functional analysis may reveal a functional relation in fewer sessions than a full functional analysis.

C

calibration The process of comparing the data produced by a measurement system to a known standard or true value and, when sources of error are found, using that information to correct or improve the measurement system.

causal relations If-then relationships (e.g., if A, then B; if B, then C) that are a central feature of understanding and doing science. With respect to stimulus relations, causal relations can define the structure of a stimulus class or define the behavior function through which stimuli in a class are transformed.

celeration The change (acceleration or deceleration) in rate of responding over time; based on count per unit of time (rate); expressed as a factor by which responding is accelerating or decelerating (multiplying or dividing); displayed with a trend line on a Standard Celeration Chart. *Celeration* is a generic term without specific reference to accelerating or decelerating rates of response. (See also **Standard Celeration Chart.**)

celeration time period A unit of time (e.g., per week, per month) in which celeration is plotted on a Standard Celeration Chart. (See also **celeration** and **celeration trend line.**)

celeration trend line The celeration trend line is measured as a factor by which rate multiplies or divides across the celeration time periods (e.g., rate per week, rate per month, rate per year, and rate per decade). (See also **celeration.**)

chained schedule A schedule of reinforcement in which the response requirements of two or more basic schedules must be met in a specific sequence before reinforcement is delivered; a discriminative stimulus is correlated with each component of the schedule.

chaining Various methods for linking specific sequences of stimuli and responses to form new performances. (See also **backward chaining, backward chaining with leaps ahead, behavior chain**, and **forward chaining.**)

changing criterion design An experimental design in which an initial baseline phase is followed by a series of treatment phases consisting of successive and gradually changing criteria for reinforcement or punishment. Experimental control is evidenced by the extent the level of responding changes to conform to each new criterion.

class expansion A new member is added to a demonstrated stimulus equivalence class as the result of teaching a new conditional discrimination.

class merger Independent equivalence classes are combined as the result of teaching a new but interrelated conditional discrimination.

class-specific reinforcement A match-to-sample procedure in which not only is the correct comparison choice conditional on the sample stimulus, but the type of consequence delivered is, too; class-specific consequences themselves become members of the equivalence classes.

clicker training A term popularized by Pryor (1999) for shaping behavior using conditioned reinforcement in the form of an auditory stimulus. A handheld device produces a click sound when pressed. The trainer pairs other forms of reinforcement (e.g., edible treats) with the click sound so that the sound becomes a conditioned reinforcer.

codic A type of verbal behavior where the form of the response is under the functional control of a verbal stimulus with point-to-point correspondence, but without formal similarity. There is also a history of generalized reinforcement.

combinatorial entailment A relation involving two stimuli that both participate in mutual entailment with some common third stimulus (See also **mutual entailment**).

Compliance Code See the **Behavior Analyst Certification Board's (BACB's) Professional and Ethical Compliance Code for Behavior Analysts.**

component analysis Any experiment designed to identify the active elements of a treatment condition, the relative contributions of different variables in a treatment package, and/or the necessary and sufficient components of an intervention. Component analyses take many forms, but the basic strategy is to compare levels of responding across successive phases in which the intervention is implemented with one or more components left out.

compound schedule A schedule of reinforcement consisting of two or more elements of continuous reinforcement (CRF), the four intermittent schedules of reinforcement (FR, VR, FI, VI), differential reinforcement of various rates of responding (DRH, DRL), and extinction. The elements from these basic schedules can occur successively or simultaneously and with or without discriminative stimuli; reinforcement may be contingent on meeting the requirements of each element of the schedule independently or in combination with all elements.

compound verbal discrimination Involves two or more verbal S^Ds (convergent multiple control) that each independently evoke behavior, but when they both occur in the same antecedent configuration, a different S^D is generated, and a more specific behavior is evoked.

concept A stimulus class whose members share a common set of features.

concept formation A complex example of stimulus control that requires stimulus generalization within a class of stimuli and discrimination between classes of stimuli.

concurrent chains design An experimental design in which participants are presented with two or more response options; each option is associated with a distinctive discriminative stimulus and leads to a different set of treatment procedures. (Also called *concurrent schedule design.*)

concurrent schedule (conc) A schedule of reinforcement in which two or more contingencies of reinforcement (elements) operate independently and simultaneously for two or more behaviors.

conditional discrimination Performance in a match-to-sample procedure in which discrimination between the comparison stimuli is conditional on, or depends on, the sample stimulus present on each trial.

conditional probability The likelihood that a target behavior will occur in a given circumstance; computed by calculating (a) the proportion of occurrences of behavior that were preceded by a specific antecedent variable and (b) the proportion of occurrences of problem behavior that were followed by a specific consequence. Conditional probabilities range from 0.0 to 1.0; the closer the conditional probability is to 1.0, the stronger the relationship is between the target behavior and the antecedent/consequence variables.

conditioned motivating operation (CMO) A motivating operation whose value-altering effect depends on a learning history. For example, because of the relation between locked doors and keys, having to open a locked door is a CMO that makes keys more effective as reinforcers, and evokes behavior that has obtained such keys.

conditioned negative reinforcer A previously neutral stimulus change that functions as a negative reinforcer because of prior pairing with one or more negative reinforcers. (See also **negative reinforcer**; compare to **unconditioned negative reinforcer.**)

conditioned punisher A previously neutral stimulus change that functions as a punisher because of prior pairing with one or more other punishers. (Sometimes called *secondary* or *learned punisher*; compare to **unconditioned punisher.**)

conditioned reflex A learned stimulus–response functional relation consisting of an antecedent stimulus (e.g., sound of refrigerator door opening) and the response it elicits (e.g., salivation); each person's repertoire of conditioned reflexes is the product of his or her history of interactions with the environment (ontogeny). (See also **respondent conditioning** and **unconditioned reflex.**)

conditioned reinforcer A stimulus change that functions as a reinforcer because of prior pairing with one or more other reinforcers. (Sometimes called *secondary* or *learned reinforcer*.)

conditioned stimulus (CS) The stimulus component of a conditioned reflex; a formerly neutral stimulus change that elicits respondent behavior only after it has been paired with an unconditioned stimulus (US) or another CS.

confidentiality Describes a situation of trust insofar as any information regarding a person receiving or having received services may not be discussed with or otherwise made available to another person or group, unless that person has provided explicit authorization, usually written and signed, for release of such information.

conflict of interest A situation in which a person in a position of responsibility or trust has competing professional or personal interests that make it difficult to fulfill his or her duties impartially.

confounding variable An uncontrolled factor known or suspected to exert influence on the dependent variable.

conjunctive schedule (conj) A schedule of reinforcement that is in effect whenever reinforcement follows the completion of response requirements for two or more schedules of reinforcement.

consequence A stimulus change that follows a behavior of interest. Some consequences, especially those that are immediate and relevant to current motivational states, have significant influence on future behavior; others have little effect. (See also **punisher** and **reinforcer.**)

constant time delay A procedure for transferring stimulus control from contrived response prompts to naturally existing stimuli. After the student has responded correctly to several 0-sec delay trials, after which presentation of the response prompt follows the instructional stimulus by a predetermined and fixed delay (usually 3 or 4 seconds) for all subsequent trials. (See also **progressive time delay**).

contextual control The situation or context in which a stimulus (or stimulus class) occurs determines its function. More specifically: a type of stimulus control requiring three levels of antecedent stimuli, such that the functions of the stimuli in a conditional discrimination vary depending on the context. Contextual control training requires a five-term contingency. It allows for the same stimuli to be members of more than one equivalence class, depending on the context.

contextual stimulus Signals the type of relational responding that will be reinforced.

contingency Refers to dependent and/or temporal relations between operant behavior and its controlling variables. (See also **contingent** and **three-term contingency.**)

contingency contract A mutually agreed-upon document between parties (e.g., parent and child) describing a contingent relationship between the completion of specified behavior(s) and access to specified reinforcer(s). (Also called **behavioral contract.**)

contingency reversal Exchanging the reinforcement contingencies for two topographically different responses. For example, if Behavior A results in reinforcement on an FR 1 schedule of reinforcement and Behavior B results in reinforcement being withheld (extinction), a contingency reversal consists of changing the contingencies such that Behavior A now results in extinction and Behavior B results in reinforcement on an FR 1 schedule.

contingency-shaped behavior Behavior acquired by direct experience with contingencies.

contingent Describes reinforcement (or punishment) that is delivered only after the target behavior has occurred.

contingency space analysis A graphic display of the probability of one event (e.g., a particular consequence) given the occurrence (or not) of another event (e.g., the presence or absence of a particular behavior). Contingencies are considered positive (i.e., a specific consequence is more likely to occur), negative (i.e., a specific consequence is less likely to occur), or neutral (i.e., a specific consequence is neither more or less likely to occur).

contingent observation A procedure for implementing time-out in which the person is repositioned within an existing setting such that observation of ongoing activities remains, but access to reinforcement is lost.

continuous measurement Measurement conducted in a manner such that all instances of the response class(es) of interest are detected during the observation period.

continuous reinforcement (CRF) A schedule of reinforcement that provides reinforcement for each occurrence of the target behavior.

contrived contingency Any contingency of reinforcement (or punishment) designed and implemented by a behavior analyst or practitioner to achieve the acquisition, maintenance, and/or generalization of a targeted behavior change. (Contrast with **naturally existing contingency.**)

contrived mediating stimulus Any stimulus made functional for the target behavior in the instructional setting that later prompts or aids the learner in performing the target behavior in a generalization setting.

copying text An elementary verbal operant involving a written response that is evoked by a written verbal discriminative stimulus that has formal similarity and a history of generalized reinforcement.

count A simple tally of the number of occurrences of a behavior. The observation period, or counting time, should always be noted when reporting *count measures*.

countercontrol Behavior evoked by coercion or aversive forms of external control; takes many forms, including escape, attack, passive resistance; "an emotional reaction of anger or frustration including operant behavior which injures or is otherwise aversive to the controller" (Skinner, 1953, p. 321).

counting time The period of time in which a count of the number of responses emitted is recorded.

cumulative record A type of graph on which the cumulative number of responses emitted is represented on the vertical axis; the steeper the slope of the data path, the greater the response rate.

cumulative recorder A device that automatically draws cumulative records (graphs) that show the rate of response in real time; each time a response is emitted, a pen moves upward across paper that continuously moves at a constant speed.

D

data The results of measurement, usually in quantifiable form; in applied behavior analysis, it refers to measures of some quantifiable dimension of a behavior. The word *data* is the plural form of datum.

data path The level and trend of behavior between successive data points; created by drawing a straight line from the center of each data point in a given data set to the center of the next data point in the same set.

deictic relation A relation between the self, as one stimulus, and other stimuli from the external world.

delay discounting A phenomenon in which delayed rewards, regardless of their significance and magnitude (e.g., enough money for a secure retirement), exert decreasing influence over choice-making behavior as a function of their temporal distance from present circumstances. Both humans and nonhuman

laboratory animals discount the value of delayed rewards; the greater the delay to the reward, the greater the discount (i.e., the less value or influence the reward has on current behavior). (Also called *temporal discounting*.)

delayed multiple baseline design A variation of the multiple baseline design in which an initial baseline, and perhaps intervention, begin for one behavior (or setting, or subject), and subsequent baselines for additional behaviors begin in a staggered or delayed fashion.

dependent group contingency A contingency in which reinforcement for all members of a group is dependent on the behavior of one member of the group or the behavior of a select group of members within the larger group.

dependent variable The measured behavior in an experiment to determine if it changes as a result of manipulations of the independent variable; in applied behavior analysis, it represents some measure of a socially significant behavior. (See also **target behavior;** compare to **independent variable.**)

deprivation The state of an organism with respect to how much time has elapsed since it has consumed or contacted a particular type of reinforcer; also refers to a procedure for increasing the effectiveness of a reinforcer (e.g., withholding a person's access to a reinforcer for a specified period prior to a session). (See also **motivating operation [MO]**; contrast with **satiation.**)

derived stimulus relations Responding indicating a relation (e.g., same as, opposite, different from, better than) between two or more stimuli that emerges as an indirect function of related instruction or experience. (Also called *emergent stimulus relations*.)

descending baseline A data path that shows a decreasing trend in the response measure over time. (Compare to **ascending baseline.**)

descriptive functional behavior assessment Direct observation of problem behavior and the antecedent and consequent events under naturally occurring conditions.

determinism The assumption that the universe is a lawful and orderly place in which phenomena occur in relation to other events and not in a willy-nilly, accidental fashion.

differential reinforcement Reinforcing only those responses within a response class that meet a specific criterion along some dimension(s) (i.e., frequency, topography, duration, latency, or magnitude) and placing all other responses in the class on extinction. (See also **differential reinforcement of alternative behavior**, **differential reinforcement of incompatible behavior**, **differential reinforcement of other behavior**, **stimulus discrimination training**, and **shaping**.)

differential reinforcement of alternative behavior (DRA) A procedure for decreasing problem behavior in which reinforcement is delivered for a behavior that serves as a desirable alternative to the behavior targeted for reduction and withheld following instances of the problem behavior (e.g., reinforcing completion of academic worksheet items when the behavior targeted for reduction is talk-outs).

differential reinforcement of diminishing rates (DRD) A schedule of reinforcement in which reinforcement is provided at the end of a predetermined interval contingent on the number of responses emitted during the interval being fewer than a gradually decreasing criterion based on the individual's performance in previous intervals (e.g., fewer than five responses per 5 minutes, fewer than four responses per 5 minutes, fewer than three responses per 5 minutes).

differential reinforcement of high rates (DRH) A schedule of reinforcement in which reinforcement is provided at the end of a predetermined interval contingent on the number of responses emitted during the interval being greater than a gradually increasing criterion based on the individual's performance in previous intervals (e.g., more than three responses per 5 minutes, more than five responses per 5 minutes, more than eight responses per 5 minutes).

differential reinforcement of incompatible behavior (DRI) A procedure for decreasing problem behavior in which reinforcement is delivered for a behavior that is topographically incompatible with the behavior targeted for reduction and withheld following instances of the problem behavior (e.g., sitting in seat is incompatible with walking around the room).

differential reinforcement of low rates (DRL) A schedule of reinforcement in which reinforcement (a) follows each occurrence of the target behavior that is separated from the previous response by a minimum interresponse time (IRT), or (b) is contingent on the number of responses within a period of time not exceeding a predetermined criterion. Practitioners use DRL schedules to decrease the rate of behaviors that occur too frequently but should be maintained in the learner's repertoire. (See also **full-session DRL, interval DRL,** and **spaced-responding DRL.**)

differential reinforcement of other behavior (DRO) A procedure for decreasing problem behavior in which reinforcement is contingent on the absence of the problem behavior during or at specific times (i.e., momentary DRO; sometimes called *differential reinforcement of zero rates of responding* or *omission training*; see also **fixed-interval DRO, fixed-momentary DRO, variable-interval DRO**, and **variable-momentary DRO.**)

direct measurement Occurs when the behavior that is measured is the same as the behavior that is the focus of the investigation. (Contrast with **indirect measurement.**)

direct replication An experiment in which the researcher attempts to duplicate exactly the conditions of an earlier experiment.

disciplinary standards Statements describing corrective, disciplinary, and revocation actions, depending on the circumstances for violations of a professional; see the BACB Compliance Code.

discontinuous measurement Measurement conducted in a manner such that some instances of the response class(es) of interest may not be detected.

discrete trial Any operant whose response rate is controlled by a given opportunity to emit the response. Each discrete response occurs when an opportunity to respond exists. *Discrete trial, restricted operant*, and *controlled operant* are synonymous technical terms. (Contrast with **free operant.**)

discriminated avoidance A contingency in which responding in the presence of a signal prevents the onset of a stimulus from which escape is a reinforcer. (See also **discriminative stimulus, discriminated operant, free-operant avoidance,** and **stimulus control.**)

discriminated operant An operant that occurs more frequently under some antecedent conditions than under others. (See also **discriminative stimulus [S^D]** and **stimulus control.**)

discriminative stimulus (S^D) A stimulus in the presence of which a given behavior has been reinforced and in the absence of which that behavior has not been reinforced; as a result of this history, an S^D evokes operant behavior because its presence signals the availability of reinforcement (See also **differential reinforcement, stimulus control, stimulus delta [S^Δ],** and **stimulus discrimination training.**)

discriminative stimulus for punishment (S^{Dp}) A stimulus in the presence of which a given behavior has been punished and in the absence of which that behavior has not been punished; as a result of this history, the behavior occurs less often in the presence of the S^{Dp} than in its absence.

distinction relation Responding jointly to two stimuli on the basis of their differences.

double-blind control A procedure that prevents the subject and the experimenter(s) from detecting the presence or absence of the treatment variable; used to eliminate confounding of results by subject expectations, parent and teacher expectations, differential treatment by others, and observer bias. (See also **placebo control.**)

DRI/DRA reversal technique An experimental technique that demonstrates the effects of reinforcement; it uses differential reinforcement of an incompatible or alternative behavior (DRI/DRA) as a control condition instead of a no-reinforcement (baseline) condition. During the DRI/DRA condition, the stimulus change used as reinforcement in the reinforcement condition is presented contingent on occurrences of a specified behavior that is either incompatible with the target behavior or an alternative to the target behavior. A higher level of responding during the reinforcement condition than during the DRI/DRA condition demonstrates that the changes in behavior are the result of *contingent reinforcement*, not simply the presentation of or contact with the stimulus event. (Compare to **DRO reversal technique** and **noncontingent reinforcement [NCR] reversal technique.**)

DRO reversal technique An experimental technique for demonstrating the effects of reinforcement by using differential reinforcement of other behavior (DRO) as a control condition instead of a no-reinforcement (baseline)

condition. During the DRO condition, the stimulus change used as reinforcement in the reinforcement condition is presented contingent on the absence of the target behavior for a specified time period. A higher level of responding during the reinforcement condition than during the DRO condition demonstrates that the changes in behavior are the result of *contingent reinforcement*, not simply the presentation of or contact with the stimulus event. (Compare to **DRI/DRA reversal technique** and **noncontingent reinforcement [NCR] reversal technique.**)

drop-out component analysis A method for conducting a component analysis in which the investigator presents the treatment package and then systematically removes components. If the treatment's effectiveness wanes when a component is removed, the researcher has identified a necessary component. (Contrast with **add-in component analysis**).

duplic A type of verbal behavior where the form of the response is under the functional control of a verbal stimulus with formal similarity, and a history of generalized reinforcement.

duration The total time that behavior occurs; measured by elapsed time from the onset of a response to its end point.

E

echoic An elementary verbal operant involving a vocal response that is evoked by a vocal verbal S^D that has formal similarity between an auditory verbal stimulus and an auditory verbal response product, and a history of generalized reinforcement.

ecological assessment An assessment protocol that acknowledges complex interrelationships between environment and behavior. An ecological assessment is a method for obtaining data across multiple settings and persons.

elementary verbal operants Michael's (1982) term for Skinner's (1957) taxonomy of five different types of speaker behavior (i.e., expressive language) distinguished by their antecedent controlling variables and related history of consequences: mand, tact, intraverbal, duplic, and codic. (See also **echoic**, **copying text, taking dictation**, and **textual behavior**).

emergent stimulus relations Stimulus relations that are not taught directly but emerge as an indirect function of related instruction or experience. (Also called *derived stimulus relations*.)

empiricism The objective observation of the phenomena of interest; objective observations are "independent of the individual prejudices, tastes, and private opinions of the scientist. . . . Results of empirical methods are objective in that they are open to anyone's observation and do not depend on the subjective belief of the individual scientist" (Zuriff, 1985, p. 9).

enriched environment An intervention that provides noncontingent access to preferred sources of reinforcement (e.g., toys, games, social and recreation activities). This noncontingent access to preferred reinforcers arranges a competition between the enriched environment and the stimulation provided by the problem behavior.

environment The conglomerate of real circumstances in which the organism or referenced part of the organism exists; behavior cannot occur in the absence of environment.

environmental enrichment (EE) An antecedent intervention that provides noncontingent access to preferred sources of reinforcement (e.g., toys, games, social and recreation activities). This noncontingent access to preferred sources of reinforcement arranges a competition between the EE intervention and the stimulation provided by the problem behavior

equal-interval scale A scale in which equal distances on the axis represent equal absolute amounts of the variable plotted on the axis (e.g., behavior change on an equal-interval vertical axis).

equivalence test A probe for the emergence of untrained stimulus–stimulus relations that evaluates both symmetry and transitivity simultaneously.

equivalence-class formation The emergence of accurate responding to untrained and nonreinforced stimulus–stimulus relations following the reinforcement of responses to some stimulus–stimulus relations. Requires successful performances on three types of probe trials—reflexivity, symmetry, and transitivity—in the absence of reinforcement. (Sometimes called *stimulus equivalence*.)

errorless learning A variety of techniques for gradually transferring stimulus control with a minimum of errors.

escape contingency A contingency in which a response terminates (produces escape from) an ongoing stimulus. (Compare to **avoidance contingency.**)

escape extinction Behaviors maintained with negative reinforcement are placed on escape extinction when those behaviors are not followed by termination of the aversive stimulus; emitting the target behavior does not enable the person to escape the aversive situation.

establishing operation (EO) A motivating operation that increases the effectiveness of some stimulus, object, or event as a reinforcer. For example, food deprivation establishes food as an effective reinforcer.

ethical codes of behavior Documents generated or adopted by professional organizations that provide clear guidelines for their members when deciding a course of proper action in conducting their professional duties.

ethics Behaviors, practices, and decisions that address such basic and fundamental questions as the following: What is the right thing to do? What's worth doing? What does it mean to be a good behavior analytic practitioner? The *Behavior Analyst Certification Board's (BACB's) Professional and Ethical Compliance Code for Behavior Analysts* details ethical practice for behavior analysts.

event recording Measurement procedure for obtaining a tally or count of the number of times a behavior occurs.

evocative effect (of a motivating operation) An increase in the current frequency of behavior that has been reinforced by some stimulus, object, or event whose reinforcing effectiveness depends on the same motivating operation. For example, food deprivation evokes (increases the current frequency of) behavior such as opening the fridge that has been reinforced by food.

exact count-per-interval IOA The percentage of total intervals in which two observers recorded the same count; the most stringent description of IOA for most data sets obtained by event recording.

exclusion (training) A procedure for building new arbitrary conditional discriminations based on the robust finding that learners will select a novel comparison stimulus over a known one in the presence of a novel sample.

exclusion time-out A procedure for implementing time-out in which, contingent on the occurrence of a target behavior, the person is removed physically from the current environment for a specified period.

experiment A carefully controlled comparison of some measure of the phenomenon of interest (the dependent variable) under two or more different conditions in which only one factor at a time (the independent variable) differs from one condition to another.

experimental analysis of behavior (EAB) A natural science approach to the study of behavior as a subject matter in its own right founded by B. F. Skinner; methodological features include rate of response as a basic dependent variable, repeated or continuous measurement of clearly defined response classes, within-subject experimental comparisons instead of group design, visual analysis of graphed data instead of statistical inference, and an emphasis on describing functional relations between behavior and controlling variables in the environment over formal theory testing.

experimental control Two meanings: (a) the outcome of an experiment that demonstrates convincingly a functional relation, meaning that experimental control is achieved when a predictable change in behavior (the dependent variable) can be reliably produced by manipulating a specific aspect of the environment (the independent variable); and (b) the extent to which a researcher maintains precise control of the independent variable by presenting it, withdrawing it, and/or varying its value, and also by eliminating or holding constant all confounding and extraneous variables. (See also **confounding variable, extraneous variable,** and **independent variable.**)

experimental design The particular type and sequence of conditions in a study so that meaningful comparisons of the effects of the presence and absence (or different values) of the independent variable can be made.

explanatory fiction A fictitious or hypothetical variable that often takes the form of another name for the observed phenomenon it claims to explain and contributes nothing to a functional account or understanding of the phenomenon, such as "intelligence" or "cognitive awareness" as explanations for why

an organism pushes the lever when the light is on and food is available but does not push the lever when the light is off and no food is available.

external validity The degree to which a study's findings have generality to other subjects, settings, and/or behaviors. (Compare to **internal validity.**)

extinction The discontinuing of a reinforcement of a previously reinforced behavior (i.e., responses no longer produce reinforcement); the primary effect is a decrease in the frequency of the behavior until it reaches a prereinforced level or ultimately ceases to occur. (See also **extinction burst** and **spontaneous recovery;** compare to **respondent extinction.**)

extinction burst An increase in the frequency of responding when an extinction procedure is initially implemented.

extinction-induced variability Phenomenon in which diverse and novel forms of behavior are sometimes observed during the extinction process.

extraneous variable Any aspect of the experimental setting (e.g., lighting, temperature) that must be held constant to prevent unplanned environmental variation.

F

fading A procedure for transferring stimulus control in which features of an antecedent stimulus (e.g., shape, size, position, color) controlling a behavior are gradually changed to a new stimulus while maintaining the current behavior; stimulus features can be faded in (enhanced) or faded out (reduced).

feature stimulus class Stimuli that share common physical forms or structures (e.g., made from wood, four legs, round, blue) or common relative relationships (e.g., bigger than, hotter than, higher than, next to). (Compare to **arbitrary stimulus class.**)

fixed interval (FI) A schedule of reinforcement in which reinforcement is delivered for the first response emitted following the passage of a fixed duration of time since the last response was reinforced (e.g., on an FI 3-min schedule, the first response following the passage of 3 minutes is reinforced).

fixed ratio (FR) A schedule of reinforcement requiring a fixed number of responses for reinforcement (e.g., an FR 4 schedule of reinforcement follows every fourth response).

fixed-interval DRO (FI-DRO) A DRO procedure in which reinforcement is available at the end of intervals of fixed duration and delivered contingent on the absence of the problem behavior during each interval. (See also **differential reinforcement of other behavior [DRO].**)

fixed-momentary DRO (FM-DRO) A DRO procedure in which reinforcement is available at specific moments in time, which are separated by a fixed amount of time, and delivered contingent on the problem not occurring at those moments. (See also **differential reinforcement of other behavior [DRO].**)

fixed-time schedule (FT) A schedule for the delivery of noncontingent stimuli in which a time interval remains the same from one delivery to the next.

formal similarity Occurs when the controlling antecedent stimulus and the response or response product (a) share the same sense mode (e.g., both stimulus and response are visual, auditory, or tactile) and (b) physically resemble each other. Verbal relations with formal similarity are echoic, copying a text, and imitation as it relates to sign language.

forward chaining A method for teaching behavior chains that begins with the learner being prompted and taught to perform the first behavior in the task analysis; the trainer completes the remaining steps in the chain. When the learner shows competence in performing the first step in the chain, he is then taught to perform the first two behaviors in the chain, with the training completing the chain. This process is continued until the learner completes the entire chain independently.

fraudulent conduct Intentional, willful, and deceitful behavior; such behavior can cause harm to others.

free operant Any operant behavior that results in minimal displacement of the participant in time and space. A free operant can be emitted at nearly any time; it is discrete, it requires minimal time for completion, and it can produce a wide range of response rates. Examples in ABA include (a) the number of words read during a 1-min counting period, (b) the number of hand slaps per 6 seconds, and (c) the number of letter strokes written in 3 minutes. (Contrast with **discrete trial.**)

free-operant avoidance A contingency in which responses at any time during an interval prior to the scheduled onset of an aversive stimulus delays the presentation of the aversive stimulus. (Contrast with **discriminated avoidance.**)

frequency How often a behavior occurs. Some behavior analysts use *frequency* to mean *rate* (a ratio of responses per standard unit of time); others use *frequency* as a synonym for count.

full-session DRL A procedure for implementing DRL in which reinforcement is delivered at the end of the session if the total number of responses emitted during the session does not exceed a criterion limit. (See also **differential reinforcement of low rates [DRL].**)

function-altering effect (relevant to operant relations) A change in an organism's repertoire of MO, stimulus, and response relations, caused by reinforcement, punishment, an extinction procedure, or a recovery from punishment procedure. Respondent function-altering effects result from the pairing and unpairing of antecedent stimuli.

function-based definition Designates responses as members of the targeted response class solely in terms of their common effect on the environment.

functional analysis A term with two meanings in contemporary behavior analysis literature. In its original and most fundamental usage, *functional analysis* denotes demonstrations of functional relations between environmental variables and behavior. In the context of determining the purposes (functions) of problem behavior for an individual, *functional analysis* entails experimentally arranging antecedents and consequences representing those in the person's natural routines so that their separate effects on problem behavior can be observed and measured.

functional behavior assessment (FBA) A systematic method of assessment for obtaining information about the purposes (functions) a problem behavior serves for a person; results are used to guide the design of an intervention for decreasing the problem behavior and increasing appropriate behavior.

functional communication training (FCT) An antecedent intervention in which an appropriate communicative behavior is taught as a replacement behavior for problem behavior usually evoked by an establishing operation (EO); involves differential reinforcement of alternative behavior (DRA).

functional relation A verbal statement summarizing the results of an experiment (or group of related experiments) that describes the occurrence of the phenomena under study as a function of the operation of one or more specified and controlled variables in the experiment in which a specific change in one event (the dependent variable) can be produced by manipulating another event (the independent variable), and that the change in the dependent variable was unlikely the result of other factors (confounding variables); in behavior analysis expressed as $b = f(x1), (x2), \ldots$, where b is the behavior and $x1$, $x2$, etc., are environmental variables of which the behavior is a function.

functionally equivalent Serving the same function or purpose; different topographies of behavior are functionally equivalent if they produce the same consequences.

G

general case analysis A systematic process for identifying and selecting teaching examples that represent the full range of stimulus variations and response requirements in the generalization setting(s). (See also **multiple-exemplar training** and **teaching enough examples.**)

generalization A generic term for a variety of behavioral processes and behavior change outcomes. (See also **generalization gradient, generalized behavior change, response generalization, response maintenance, setting/situation generalization,** and **stimulus generalization.**)

generalization across subjects Changes in the behavior of people not directly treated by an intervention as a function of treatment contingencies applied to other people.

generalization probe Any measurement of a learner's performance of a target behavior in a setting and/or stimulus situation in which direct training has not been provided.

generalization setting Any place or stimulus situation that differs in some meaningful way from the instructional setting and in which performance of the target behavior is desired. (Contrast with **instructional setting.**)

generalized behavior change A behavior change that has not been taught directly. Generalized outcomes take one, or a combination of, three primary forms: response maintenance, stimulus/setting generalization, and response generalization. (Sometimes called *generalized outcome.*)

generalized conditioned reinforcer A conditioned reinforcer that as a result of having been paired with many other reinforcers does not depend on an establishing operation for any particular form of reinforcement for its effectiveness.

generalized imitation A term often used when a learner imitates a wide variety of unprompted, untrained, non-reinforced modeled behaviors in different settings and situations. Generalized imitation could be considered a higher order response class in which participants imitate novel models without training and that are not predictive of reinforcement.

generative learning A behavioral effect whereby previously acquired speaker and listener skills enable or accelerate the acquisition of other speaker and listener skills, without dependence on direct teaching or a history of reinforcement.

generic (tact) extension A tact evoked by a novel stimulus that shares all of the relevant or defining features associated with the original stimulus.

Good Behavior Game An interdependent group contingency in which a group is divided into two or more teams that compete against each other and/or a specified criterion. The team with fewest marks at the end of the game earns a reinforcer. Each team is also told that it can earn a reinforcer if it has fewer than a specified number of marks.

graph A visual format for displaying data; reveals relations among and between a series of measurements and relevant variables.

group contingency A contingency in which reinforcement for all members of a group is dependent on the behavior of (a) a person within the group, (b) a select group of members within the larger group, or (c) each member of the group meeting a performance criterion. (See also **dependent group contingency, independent group contingency,** and **interdependent group contingency.**)

H

habilitation Habilitation (adjustment) occurs when a person's repertoire has been changed such that short- and long-term reinforcers are maximized and short- and long-term punishers are minimized.

habit reversal A multiple-component treatment package for reducing unwanted habits such as fingernail biting and muscle tics; treatment typically includes self-awareness training involving response detection and procedures for identifying events that precede and trigger the response; competing response training; and motivation techniques including self-administered consequences, social support systems, and procedures for promoting the generalization and maintenance of treatment gains.

habituation A decrease in responsiveness to repeated presentations of a stimulus; most often used to describe a reduction of respondent behavior as a function of repeated presentation of the eliciting stimulus over a short span of time; some researchers suggest that the concept also applies to within-session changes in operant behavior.

hero procedure A term sometimes used for a dependent group contingency (i.e., a reward for the group is contingent upon the behavior of an individual group member).

hierarchical relation A nested stimulus relation in which a category, subsuming multiple stimuli, is itself a member of a higher-order category subsuming multiple stimuli.

high-probability (high-*p*) request sequence An antecedent intervention in which two to five easy tasks with a known history of learner compliance (the high-*p* requests) are presented in quick succession immediately before requesting the target task, the low-*p* request. (Also called *interspersed requests, pretask requests,* or *behavioral momentum.*)

high-probability instructional sequence (high-*p*). A procedure for improving compliance and diminishing escape-maintained problem behaviors. The practitioner presents two to five easy-to-follow (high-*p*) instructions for which the participant has a history of compliance. When the learner complies with several high-*p* instructions, the practitioner immediately presents a target instruction (i.e., low-*p*).

higher-order conditioning Development of a conditioned reflex by pairing of a neutral stimulus (NS) with a conditioned stimulus (CS). (Also called *secondary conditioning.*)

higher-order operant class Behavior defined in terms of general relations between antecedents and responses, rather than in terms of specific stimuli and responses; examples include generalized imitation, manding, instruction following, naming, and relational framing.

history of reinforcement An inclusive term referring in general to all of a person's learning experiences and more specifically to past conditioning with respect to particular response classes or aspects of a person's repertoire. (See also **ontogeny.**)

hypothetical construct A presumed but unobserved process or entity (e.g., Freud's id, ego, and superego).

I

imitation Behavior that (a) is occasioned by another person's model of the behavior (or symbolic representation thereof), (b) has formal similarity with the model, (c) follows the modeled behavior closely in time, and (d) the model is the primary controlling variable for the imitative behavior. An imitative behavior is a new behavior emitted following a novel antecedent event (i.e., the model). (See also **formal similarity;** contrast with **echoic.**)

imitation training A systematic, research-based set of procedures for teaching a nonimitative learner to imitate models of novel behaviors.

impure tact A verbal operant involving a response that is evoked by both an MO and a nonverbal stimulus; thus, the response is part mand and part tact. (See also **mand** and **tact.**)

independent group contingency A contingency in which reinforcement for each member of a group is dependent on that person's meeting a performance criterion that is in effect for all members of the group.

independent variable The variable that is systematically manipulated by the researcher in an experiment to see whether changes in the independent variable produce reliable changes in the dependent variable. In applied behavior analysis, it is usually an environmental event or condition antecedent or consequent to the dependent variable. (Sometimes called the *intervention* or *treatment variable*; compare to **dependent variable.**)

indirect functional assessment Structured interviews, checklists, rating scales, or questionnaires used to obtain information from people who are familiar with the person exhibiting the problem behavior (e.g., teachers, parents, caregivers, and/or the individual himself or herself); used to identify conditions or events in the natural environment that correlate with the problem behavior.

indirect measurement Occurs when the behavior that is measured is in some way different from the behavior of interest; considered less valid than direct measurement because inferences about the relation between the data obtained and the actual behavior of interest are required. (Contrast with **direct measurement.**)

indiscriminable contingency A contingency that makes it difficult for the learner to discriminate whether the next response will produce reinforcement. Practitioners use indiscriminable contingencies in the form of intermittent schedules of reinforcement and delayed rewards to promote generalized behavior change.

informed consent Formal permission—usually written, signed, and dated—given by a potential recipient of behavioral services or participant in a research study; requires that full disclosure of all pertinent information be provided to the individual prior to a granting of permission. To give consent, the person must (a) demonstrate the capacity to decide, (b) do so voluntarily, and (c) have adequate knowledge of all salient aspects of the treatment.

instructional setting The environment where instruction occurs; includes all aspects of the environment, planned and unplanned, that may influence the

learner's acquisition, maintenance, and generalization of the target behavior. (Contrast with **generalization setting.**)

interdependent group contingency A contingency in which reinforcement for all members of a group is dependent on each member of the group meeting a performance criterion that is in effect for all members of the group.

intermittent schedule of reinforcement (INT) A contingency of reinforcement in which some, but not all, occurrences of the behavior produce reinforcement.

internal validity The extent to which an experiment shows convincingly that changes in behavior are a function of the independent variable and not the result of uncontrolled or unknown variables. (Compare to **external validity.**)

interobserver agreement (IOA) The degree to which two or more independent observers report the same observed values after measuring the same events.

interresponse time (IRT) A measure of temporal locus, defined as the elapsed time between two successive responses.

interrupted chain procedure A procedural variation of the behavior chain interruption strategy, entails arranging the environment such that the learner is unable to continue the chain at a predetermined point until responding to a prompt (e.g., "What do you want?").

interval DRL A procedure for implementing DRL in which the total session is divided into equal intervals and reinforcement is provided at the end of each interval in which the number of responses during the interval is equal to or below a criterion limit. (See also **differential reinforcement of low rates [DRL].**)

interval-by-interval IOA An index of the agreement between observers for data obtained by interval recording or time sampling measurement; calculated for a given session or measurement period by comparing the two observers' recordings of the occurrence or nonoccurrence of the behavior in each observation interval and dividing the number of intervals of agreement by the total number of intervals and multiplying by 100. (Also called the *point-by-point* or *total interval IOA*; compare to **scored-interval IOA** and **unscored-interval IOA.**)

interview-informed synthesized contingency analysis A variation of functional analysis designed to increase efficiency. In the test condition, multiple contingencies are implemented simultaneously (e.g., attention and escape) when the problem behavior is demonstrated. In the control condition, those same contingencies are presented noncontingently and continuously.

intraverbal An elementary verbal operant involving a response that is evoked by a verbal discriminative stimulus that does *not* have point-to-point correspondence with that verbal stimulus. The intraverbal is the opposite of the echoic, in that the words emitted by one speaker do not match the words of another speaker. Intraverbal behavior constitutes the basis for social interaction, conversations, and much of academic and intellectual behavior. Questions are mands, and answers are intraverbal.

intraverbal control Some verbal stimuli only supplement other more critical antecedents, but nonetheless they play a causal role in evoking behavior. Palmer (2016) recommends "In cases in which the verbal antecedent is, by itself, insufficient to evoke the relevant response, we should speak of 'intraverbal control,' usually as one of a number of concurrent controlling variables" (p. 99).

irreversibility A situation that occurs when the level of responding observed in a previous phase cannot be reproduced even though the experimental conditions are the same as they were during the earlier phase.

J

joint control A phenomenon in which two separate, but interrelated forms of a person's own verbal behavior, combine to acquire stimulus control of a response that would not have occurred in the absence of either.

L

lag reinforcement schedule A schedule of reinforcement in which reinforcement is contingent on a response being different in some specified way (e.g., different topography) from the previous response (e.g., Lag 1) or a specified number of previous responses (e.g., Lag 2 or more).

latency See **response latency.**

latency-based functional analysis An analysis in which each session is terminated as soon as a problem behavior occurs. The index of problem behavior is the latency from onset of the establishing operation to the first occurrence of the problem behavior.

least-to-most response prompts A technique of transferring stimulus control in which the practitioner gives the participant an opportunity to perform the response with the least amount of assistance on each trial. The participant receives greater degrees of assistance with each successive trial without a correct response. The procedure for least-to-most prompting requires the participant to make a correct response within a set time limit (e.g., 3 seconds) from the presentation of the natural S^D. If the response does not occur within the specified time, the applied behavior analyst presents the natural S^D and a response prompt of least assistance, such as a verbal response prompt. If after the same specified time limit (e.g., another 3 seconds) the participant does not make a correct response, the analyst gives the natural S^D and another response prompt, such as a gesture. The participant receives partial or full physical guidance if the less intrusive prompt does not evoke a correct response.

level The value on the vertical axis around which a series of behavioral measures converge.

level system A component of some token economy systems in which participants advance up (or down) through a succession of levels contingent on their behavior at the current level. The performance criteria and sophistication or difficulty of the behaviors required at each level are higher than those of preceding levels; as participants advance to higher levels, they gain access to more desirable reinforcers, increased privileges, and greater independence.

limited hold A situation in which reinforcement is available only during a finite time following the elapse of an FI or VI interval; if the target response does not occur within the time limit, reinforcement is withheld and a new interval begins (e.g., on an FI 5-min schedule with a limited hold of 30 seconds, the first correct response following the elapse of 5 minutes is reinforced only if that response occurs within 30 seconds after the end of the 5-minute interval).

line graph Based on a Cartesian plane, a two-dimensional area formed by the intersection of two perpendicular lines. Any point within the plane represents a specific relation between the two dimensions described by the intersecting lines. It is the most common graphic format for displaying data in applied behavior analysis.

listener Someone who provides reinforcement for a speaker's verbal behavior. A listener may also serve as an audience evoking verbal behavior. The distinction between listener and speaker is often blurred by the fact that much of a listener's behavior may involve becoming a speaker at the covert level (e.g., thinking about what was said). A speaker may also serve as her own listener. (Contrast with **speaker.**)

listener discriminations When verbal S^D evokes a specific nonverbal behavior, due to a history of reinforcement.

local response rate The average rate of response during a smaller period of time within a larger period for which an overall response rate has been given. (See also **overall response rate.**)

M

magnitude The force or intensity with which a response is emitted; provides important quantitative parameters used in defining and verifying the occurrence of some response classes. Responses meeting those criteria are measured and reported by one or more fundamental or derivative measures such as frequency, duration, or latency. (Sometimes called *amplitude*.)

maintenance Two different meanings in applied behavior analysis: (a) the extent to which the learner continues to perform the target behavior after a portion or all of the intervention has been terminated (i.e., response maintenance), a dependent variable or characteristic of behavior; and (b) a condition in which treatment has been discontinued or partially withdrawn, an independent variable or experimental condition.

mand An elementary verbal operant involving a response of any form that is evoked by an MO and followed by specific reinforcement. Manding allows a speaker to get what she wants or refuse what she does not want.

massed practice A self-directed behavior change technique in which the person forces herself to perform an undesired behavior (e.g., a compulsive ritual) repeatedly, which sometimes decreases the future frequency of the behavior.

matching law The allocation of responses to choices available on concurrent schedules of reinforcement; rates of responding across choices are distributed in proportions that match the rates of reinforcement received from each choice alternative.

matching-to-sample procedure A discrete trial procedure for investigating conditional relations and stimulus equivalence. A matching-to-sample trial begins with the participant making a response that presents or reveals the sample stimulus; next, the sample stimulus may or may not be removed, and two or more comparison stimuli are presented. The participant then selects one of the comparison stimuli. Responses that select a comparison stimulus that matches the sample stimulus are reinforced; no reinforcement is provided for responses selecting the nonmatching comparison stimuli.

mean count-per-interval IOA The average percentage of agreement between the counts reported by two observers in a measurement period composed of a series of smaller counting times; a more conservative measure of IOA than total count IOA.

mean duration-per-occurrence IOA An IOA index for duration per occurrence data; also a more conservative and usually more meaningful assessment of IOA for total duration data calculated for a given session or measurement period by computing the average percentage of agreement of the durations reported by two observers for each occurrence of the target behavior.

measurement The process of applying quantitative labels to describe and differentiate objects and natural events. Measurement in applied behavior analysis involves three steps: (a) identifying the behavior to be measured, (b) defining the behavior in observable terms, and (c) selecting an appropriate observation and data-recording method.

measurement bias Nonrandom measurement error; a form of inaccurate measurement in which the data consistently overestimate or underestimate the true value of an event.

measurement by permanent product A method of measuring behavior after it has occurred by recording the effects that the behavior produced on the environment.

mentalism An approach to explaining behavior that assumes that a mental, or "inner," dimension exists that differs from a behavioral dimension and that phenomena in this dimension either directly cause or at least mediate some forms of behavior, if not all.

metaphorical (tact) extension A tact evoked by a novel stimulus that shares some, but not all, of the relevant features of the original stimulus.

methodological behaviorism A philosophical position that views behavioral events that cannot be publicly observed as outside the realm of science.

metonymical (tact) extension A tact evoked by a novel stimulus that shares none of the relevant features of the original stimulus configuration, but some irrelevant yet related feature has acquired stimulus control.

mixed schedule (mix) A compound schedule of reinforcement consisting of two or more basic schedules of reinforcement (elements) that occur in an alternating, usually random, sequence; no discriminative stimuli are correlated with the presence or absence of each element of the schedule, and reinforcement is delivered for meeting the response requirements of the element in effect at any time.

modeling A behavior change strategy in which learners acquire new skills by imitating demonstrations of the skills by live or symbolic models. The model shows, demonstrates, or conveys exactly the behavior the learner is expected to perform. Models can be live demonstrations or symbolic representations of the desired behavior.

momentary time sampling A measurement method in which the presence or absence of behaviors is recorded at precisely specified time intervals. (Contrast with **interval recording.**)

most-to-least response prompts A technique of transferring stimulus control in which the practitioner physically guides the participant through the entire performance sequence, and then gradually reduces the level of assistance in successive trials. Customarily, most-to-least prompting transitions from physical guidance to visual prompts to verbal instructions, and finally to the natural stimulus without prompts.

motivating operation (MO) An environmental variable that (a) alters (increases or decreases) the reinforcing or punishing effectiveness of some stimulus, object, or event; and (b) alters (increases or decreases) the current frequency of all behavior that has been reinforced or punished by that stimulus, object, or event. (See also **abative effect, abolishing operation [AO], behavior-altering effect, establishing operation [EO], evocative effect, value-altering effect.**)

motor imitation (relating to sign language) A type of duplic verbal behavior in which the form of a motor response is under the functional control of a visual verbal S^D that has formal similarity between a verbal stimulus and a verbal response product, and a history of generalized reinforcement.

multielement design An experimental design in which two or more conditions (one of which may be a no-treatment control condition) are presented in rapidly alternating succession (e.g., on alternating sessions or days) independent of the level of responding; differences in responding between or among conditions are attributed to the effects of the conditions. (Also called *alternating treatments design, concurrent schedule design*, and *multiple schedule design.*)

multiple baseline across behaviors design A multiple baseline design in which the treatment variable is applied to two or more different behaviors of the same subject in the same setting.

multiple baseline across settings design A multiple baseline design in which the treatment variable is applied to the same behavior of the same subject across two or more different settings, situations, or time periods.

multiple baseline across subjects design A multiple baseline design in which the treatment variable is applied to the same behavior of two or more subjects (or groups) in the same setting.

multiple baseline design An experimental design that begins with the concurrent measurement of two or more behaviors in a baseline condition, followed by the application of the treatment variable to one of the behaviors while baseline conditions remain in effect for the other behavior(s). After maximum change has been noted in the first behavior, the treatment variable is applied in sequential fashion to each of the other behaviors in the design. Experimental control is demonstrated if each behavior shows similar changes when, and only when, the treatment variable is introduced. (See also **multiple baseline across behaviors design**, **multiple baseline across settings design**, and **multiple baseline across subjects design**.)

multiple control (of verbal behavior) There are two types of multiple control. *Convergent multiple control* occurs when a single verbal response is a function of more than one variable (i.e., what is said has more than one antecedent source of control). *Divergent multiple control* occurs when a single antecedent variable affects the strength of more than one response.

multiple-exemplar training Instruction that provides the learner with practice with a variety of stimulus conditions, response variations, and response topographies to ensure the acquisition of desired stimulus control response forms; used to promote both setting/situation generalization and response generalization. (See also **teaching enough examples.**)

multiple probe design A variation of the multiple baseline design that features intermittent measures, or probes, during baseline. It is used to evaluate the effects of instruction on skill sequences in which it is unlikely that the subject can improve performance on later steps in the sequence before learning prior steps.

multiple schedule (mult) A compound schedule of reinforcement consisting of two or more basic schedules of reinforcement (elements) that occur in an alternating, usually random, sequence; a discriminative stimulus is correlated with the presence or absence of each element of the schedule, and reinforcement is delivered for meeting the response requirements of the element in effect at any time.

multiple treatment interference The effects of one treatment on a subject's behavior being confounding by the influence of another treatment administered in the same study.

multiple treatment reversal design Any experimental design that uses the experimental methods and logic of the reversal tactic to compare the effects of two or more experimental conditions to baseline and/or to one another (e.g., A-B-A-B-C-B-C, A-B-A-C-A-D-A-C-A-D, A-B-A-B-B+C-B-B+C).

mutual entailment A bidirectional stimulus relation in which one direction (e.g., if A, then B) is directly learned and the other (if B, then A) is derived.

N

naive observer An observer who is unaware of the study's purpose and/or the experimental conditions in effect during a given phase or observation period. Data obtained by a naive observer are less likely to be influenced by observers' expectations.

naturally existing contingency Any contingency of reinforcement (or punishment) that operates independent of the behavior analyst's or practitioner's efforts; includes socially mediated contingencies contrived by other people and already in effect in the relevant setting. (Contrast with **contrived contingency.**)

negative punishment A response behavior followed immediately by the removal of a stimulus (or a decrease in the intensity of the stimulus) that results in similar responses occurring less often. (Contrast with **positive punishment.**)

negative reinforcement A contingency in which the occurrence of a response is followed immediately by the termination, reduction, postponement, or avoidance of a stimulus, and which leads to an increase in the future occurrence of similar responses.

negative reinforcer A stimulus whose termination (or reduction in intensity) functions as reinforcement. (Contrast with **positive reinforcer.**)

negligence Failure to demonstrate professional integrity on the part of the provider that threatens the client's health and safety; typically exhibited as nonfeasance—not doing what ought to be done.

neutral stimulus (NS) A stimulus change that does not elicit respondent behavior. (Compare to **conditioned stimulus [CS]** and **unconditioned stimulus [US].**)

nodal stimulus (node) A stimulus set that must be held in common across a minimum of two conditional discriminations to provide a basis for all equivalence properties.

nonequivalence relations Derived stimulus relations in which stimuli are related on some basis other than "sameness."

noncontingent reinforcement (NCR) A procedure in which stimuli with known reinforcing properties are presented on fixed-time (FT) or variable-time (VT) schedules completely independent of behavior; often used as an antecedent intervention to reduce problem behavior. (See also **fixed-time schedule [FT], variable-time schedule [VT].**)

noncontingent reinforcement (NCR) reversal technique An experimental control technique that demonstrates the effects of reinforcement by using noncontingent reinforcement (NCR) as a control condition instead of a no-reinforcement (baseline) condition. During the NCR condition, the stimulus change used as reinforcement in the reinforcement condition is presented on a fixed or variable time schedule independent of the subject's behavior. A higher level of responding during the reinforcement condition than during the NCR condition demonstrates that the changes in behavior are the result of *contingent reinforcement*, not simply the presentation of or contact with the stimulus event. (Compare to **DRI/DRA reversal technique** and **DRO reversal technique.**)

nonconcurrent multiple baseline across participants design An experimental design that consists of a related series of A-B (baseline-intervention) sequences conducted across participants at different points in time; often used to assess treatment effects when concurrent measurement of participants' behavior is not possible.

nonexclusion time-out A procedure for implementing time-out in which, contingent on the occurrence of the target behavior, the person remains within the setting, but does not have access to reinforcement, for a specified period.

normalization As a philosophy and principle, the belief that people with disabilities should, to the maximum extent possible, be physically and socially integrated into the mainstream of society regardless of the degree or type of disability. As an approach to intervention, the use of progressively more typical settings and procedures "to establish and/or maintain personal behaviors which are as culturally normal as possible" (Wolfensberger, 1972, p. 28).

O

observed value A measure produced by an observation and measurement system. Observed values serve as the data that the researcher and others will interpret to form conclusions about an investigation. (Compare to **true value.**)

observer drift Any unintended change in the way an observer uses a measurement system over the course of an investigation that results in measurement error; often entails a shift in the observer's interpretation of the original definitions of the target behavior subsequent to being trained. (See also **measurement bias** and **observer reactivity.**)

observer reactivity Influence on the data reported by an observer that results from the observer's awareness that others are evaluating the data. (See also **measurement bias** and **observer drift.**)

ontogeny The history of the development of an individual organism during its lifetime. (See also **history of reinforcement;** compare to **phylogeny.**)

operant behavior Behavior that is selected, maintained, and brought under stimulus control as a function of its consequences; each person's repertoire of operant behavior is a product of his history of interactions with the environment (ontogeny).

operant conditioning The basic process by which operant learning occurs; consequences (stimulus changes immediately following responses) result in an increased (reinforcement) or decreased (punishment) frequency of the same type of behavior under similar motivational and environmental conditions in the future. (See also **motivating operation, punishment, reinforcement, response class,** and **stimulus control.**)

overall response rate The rate of response over a given time period. (See also **local response rate.**)

overcorrection A behavior change tactic based on positive punishment in which, contingent on the problem behavior, the learner is required to engage in effortful behavior directly or logically related to fixing the damage caused by the behavior. Forms of overcorrection are restitutional overcorrection and positive practice overcorrection. (See also **positive practice overcorrection** and **restitutional overcorrection.**)

overselective stimulus control A condition in which the range of discriminative stimuli, or stimulus features controlling behavior, is extremely limited; often interferes with learning. (Also called *stimulus overselectivity.*)

overshadowing Occurs when the most salient component of a compound stimulus arrangement controls responding and interferes with the acquisition of stimulus control by the more relevant stimulus.

P

parametric analysis An experiment designed to discover the differential effects of a range of values of an independent variable.

parsimony The practice of ruling out simple, logical explanations, experimentally or conceptually, before considering more complex or abstract explanations.

partial-interval recording A time sampling method for measuring behavior in which the observation period is divided into a series of brief time intervals (typically from 5 to 10 seconds). The observer records whether the target behavior occurred at any time during the interval. Partial-interval recording is not concerned with how many times the behavior occurred during the interval or how long the behavior was present, just that it occurred at some point during the interval; tends to overestimate the proportion of the observation period that the behavior actually occurred.

partition time-out A variation of time-out from positive reinforcement in which contingent on the occurrence of the target behavior, the participant remains in the time-in setting, but his view of the setting is restricted by a panel or cubicle, or a select space is arranged to serve as the time-out area (i.e., a carpet, a corner). Sometimes called *select space time-out.*

percentage A ratio (i.e., a proportion) formed by combining the same dimensional quantities, such as count (number ÷ number) or time (duration ÷ duration; latency ÷ latency); expressed as a number of parts per 100; typically expressed as a ratio of the number of responses of a certain type per total number of responses (or opportunities or intervals in which such a response could have occurred). A percentage presents a proportional quantity per 100.

perspective shifting Responding as if from the vantage point of another person, place, or time than the personal here and now.

philosophic doubt An attitude that the truthfulness and validity of all scientific theory and knowledge should be continually questioned.

phylogeny The history of the natural evolution of a species. (Compare to **ontogeny.**)

pivotal behavior A behavior that, when learned, produces corresponding modifications or covariation in other untrained behaviors. (Compare to **behavioral cusp.**)

placebo control A procedure that prevents a subject from detecting the presence or absence of the treatment variable. To the subject, the placebo condition appears the same as the treatment condition (e.g., a placebo pill contains an inert substance but looks, feels, and tastes exactly like a pill that contains the treatment drug). (See also **double-blind control.**)

planned activity check (PLACHECK) A variation of momentary time sampling in which the observer records whether each person in a group is engaged in the target behavior at specific points in time; provides a measure of "group behavior."

planned ignoring A procedure for implementing time-out in which social reinforcers—usually attention, physical contact, and verbal interaction—are withheld for a brief period contingent on the occurrence of the target behavior.

point-to-point correspondence A relation between the stimulus and response or response product that occurs when the beginning, middle, and end of the verbal stimulus matches the beginning, middle, and end of the verbal response. The verbal relations with point-to-point correspondence are echoic, copying text, imitation as it relates to sign language, textual, and transcription.

positive practice overcorrection A form of overcorrection in which, contingent on an occurrence of the target behavior, the learner is required to repeat a correct form of the behavior, or a behavior incompatible with the problem behavior, a specified number of times; entails an educative component. (See also **overcorrection** and **restitutional overcorrection.**)

positive punishment A response followed immediately by the presentation of a stimulus that decreases the future frequency of the behavior. (Contrast with **negative punishment.**)

positive reinforcement A response followed immediately by the presentation of a stimulus change that results in similar responses occurring more often. (Contrast with **negative reinforcement.**)

positive reinforcer A stimulus whose presentation or onset functions as reinforcement. (Contrast with **negative reinforcer.**)

postreinforcement pause The absence of responding for a period of time following reinforcement; an effect commonly produced by fixed interval (FI) and fixed ratio (FR) schedules of reinforcement.

practice effects Improvements in performance resulting from opportunities to perform a behavior repeatedly so that baseline measures can be obtained.

pragmatism A philosophical position asserting that the truth value of a statement is determined by how well it promotes effective action; pragmatism is a primary criterion by which behavior analysts judge the value of their findings.

precision teaching An instructional approach that involves (a) pinpointing the skills to be learned; (b) measuring the initial frequency or rate per minute at which the student can perform those skills; (c) setting an aim, or goal, for the child's improvement; (d) using direct, daily measurement to monitor progress made under an instructional program; (e) charting the results of those measurements on a Standard Celeration Chart; and (f) changing the program if progress is not adequate.

prediction A statement of the anticipated outcome of a presently unknown or future measurement; one of three components of the experimental reasoning, or baseline logic, used in single-subject research designs. (See also **replication** and **verification.**)

Premack principle A principle that states that making the opportunity to engage in a high-probability behavior contingent on the occurrence of a low-frequency behavior will function as reinforcement for the low-frequency behavior. Sometimes called "Grandma's Law." (See also **response-deprivation hypothesis.**)

principle of behavior A statement describing a functional relation between behavior and one or more of its controlling variables with generality across organisms, species, settings, behaviors, and time (e.g., extinction, positive reinforcement); an empirical generalization inferred from many experiments demonstrating the same functional relation.

private events Covert events typically accessible only to the person experiencing them. Skinner's radical behaviorism holds three major assumptions about private events: (a) private events are behavior; (b) behavior that takes place within the skin is distinguished from other ("public") behavior only by its inaccessibility; and (c) private behavior is influenced by (i.e., is a function of) the same kinds of variables as publicly accessible behavior.

procedural fidelity The extent to which procedures in all phases and conditions of an experiment, including baseline, are implemented correctly. (Contrast with **treatment integrity).**

programming common stimuli A tactic for promoting setting/situation generalization by making the instructional setting similar to the generalization setting; the two-step process involves (1) identifying salient stimuli that characterize the generalization setting and (2) incorporating those stimuli into the instructional setting.

progressive-ratio (PR) schedule of reinforcement A variation of the fixed ratio (FR) schedule of reinforcement that increases the ratio requirements incrementally within the session; PR schedule requirements are changed using (a) arithmetic progressions to add a constant number to each successive ratio, or (b) geometric progressions to add successively a constant proportion of the preceding ratio.

progressive schedule of reinforcement A schedule that systematically thins each successive reinforcement opportunity independent of the individual's behavior; progressive ratio (PR) and progressive interval (PI) schedules are thinned using arithmetic or geometric progressions.

progressive time delay A procedure for transferring stimulus control from contrived response prompts to naturally existing stimuli that starts with simultaneous presentation of the natural stimulus and the response prompt (i.e., 0-sec delay). The number of 0-sec trials depends on the task difficulty and the functioning level of the participant. Following the simultaneous presentations, the time delay is gradually and systematically extended.

punisher A stimulus change that decreases the future occurrence of behavior that immediately precedes it. (See also **aversive stimulus, conditioned punisher,** and **unconditioned punisher.**)

punishment A basic principle of behavior describing a response–consequence functional relation in which a response is followed immediately by a stimulus change that decreases future occurrences of that type of behavior.(See also **negative punishment** and **positive punishment.**)

R

radical behaviorism A form of behaviorism that attempts to understand all human behavior, including private events such as thoughts and feelings, in terms of controlling variables in the history of the person (ontogeny) and the species (phylogeny).

range-bound changing criterion design A variation of the changing criterion design in which each intervention sub-phase includes a lower and an upper criterion within which the participant is expected to perform.

rate A fundamental measure of how often behavior occurs expressed as count per standard unit of time (e.g., per minute, per hour, per day) and calculated by dividing the number of responses recorded by the number of standard units of time in which observations were conducted. Some behavior analysts use *rate* and *frequency* interchangeably; others use *frequency* to mean count. (See **frequency** and **count.**)

ratio scale A scale in which equal distances on a graph's axis correspond to equal ratios of change in the variable plotted on the axis.

ratio strain A behavioral effect associated with abrupt increases in ratio requirements when moving from denser to thinner reinforcement schedules; common effects include avoidance, aggression, and unpredictable pauses or cessation in responding.

reactivity Effects of an observation and measurement procedure on the behavior being measured. Reactivity is most likely when measurement procedures are obtrusive, especially if the person being observed is aware of the observer's presence and purpose.

recombinative generalization "Differential responding to novel combinations of stimulus components that have been included previously in other stimulus contexts" (Goldstein, 1983, p. 280).

recovery from punishment The occurrence of a previously punished type of response without its punishing consequence; analogous to the extinction of previously reinforced behavior and has the effect of undoing the effect of the punishment.

reflex A stimulus–response relation consisting of an antecedent stimulus and the respondent behavior it elicits (e.g., bright light–pupil contraction). Unconditioned and conditioned reflexes protect against harmful stimuli, help regulate the internal balance and economy of the organism, and promote reproduction. (See also **conditioned reflex, respondent behavior, respondent conditioning,** and **unconditioned reflex.**)

reflexive conditioned motivating operation (CMO-R) A stimulus that acquires MO effectiveness by preceding some form of worsening or improvement. It is exemplified by the warning stimulus in a typical escape–avoidance procedure, which establishes its own offset as reinforcement and evokes all behavior that has accomplished that offset.

reflexivity A type of stimulus-to-stimulus relation in which the learner, without any prior training or reinforcement for doing so, selects a comparison stimulus that is the same as the sample stimulus (e.g., A = A). Reflexivity would be demonstrated in the following matching-to-sample procedure: The sample stimulus is a picture of a tree, and the three comparison stimuli are a picture of a mouse, a picture of a cookie, and a duplicate of the tree picture used as the sample stimulus. The learner selects the picture of the tree without specific reinforcement in the past for making the tree-picture-to-tree-picture match. (Also called *generalized identity matching*; see also **stimulus equivalence;** compare to **transitivity** and **symmetry.**)

reinforcement A basic principle of behavior describing a response–consequence functional relation in which a response is followed immediately by a stimulus change that results in similar responses occurring more often. (See also **negative reinforcement** and **positive reinforcement.**)

reinforcer A stimulus change that increases the future frequency of behavior that immediately precedes it. (See also **positive reinforcer, conditioned reinforcer** and **unconditioned reinforcer.**)

reinforcer assessment Refers to a variety of direct, empirical methods for presenting one or more stimuli contingent on a target response and measuring their effectiveness as reinforcers.

reinforcer-abolishing effect (of a motivating operation) A decrease in the reinforcing effectiveness of a stimulus, object, or event caused by a motivating operation. For example, food ingestion abolishes (decreases) the reinforcing effectiveness of food.

reinforcer-establishing effect (of a motivating operation) An increase in the reinforcing effectiveness of a stimulus, object, or event caused by a motivating operation. For example, food deprivation establishes (increases) the reinforcing effectiveness of food.

relational frame Any specific type of arbitrarily applicable relational responding.

relational frame theory (RFT) A theory of derived stimulus relations proposing that stimulus relations are inherently verbal and that accumulated experience with relational exemplars creates generalized repertoires of relating.

relevance of behavior rule Holds that only behaviors likely to produce reinforcement in the person's natural environment should be targeted for change.

reliability (of measurement) Refers to the consistency of measurement, specifically, the extent to which repeated measurement of the same event yields the same values.

repeatability Refers to the fact that a behavior can occur repeatedly through time (i.e., behavior can be counted); one of the three dimensional quantities of behavior from which all behavioral measurements are derived. (See also **celeration, count, frequency, rate, temporal extent,** and **temporal locus.**)

repertoire All of the behaviors a person can do; or a set of behaviors relevant to a particular setting or task (e.g., gardening, mathematical problem solving).

replication (a) Repeating conditions within an experiment to determine the reliability of effects and increase internal validity. (See also **baseline logic, prediction,** and **verification.**) (b) Repeating whole experiments to determine the generality of findings of previous experiments to other subjects, settings, and/or behaviors. (See also **direct replication, external validity,** and **systematic replication.**)

research question A statement of what the researcher seeks to learn by conducting the experiment; may be presented in question form and is most often found in a published account as a statement of the experiment's purpose. All aspects of an experiment's design should follow from the research question.

resistance to extinction The relative frequency with which operant behavior is emitted during extinction.

respondent behavior The response component of a reflex; behavior that is elicited, or induced, by antecedent stimuli. (See also **reflex** and **respondent conditioning.**)

respondent conditioning A stimulus–stimulus pairing procedure in which a neutral stimulus (NS) is presented with an unconditioned stimulus (US) until the neutral stimulus becomes a conditioned stimulus that elicits the conditioned response. (Also called *classical* or *Pavlovian conditioning*; see also **conditioned reflex** and **higher order conditioning.**)

respondent extinction The repeated presentation of a conditioned stimulus (CS) in the absence of the unconditioned stimulus (US); the CS gradually loses its ability to elicit the conditioned response until the conditioned reflex no longer appears in the individual's repertoire.

response A single instance or occurrence of a specific class or type of behavior. Technical definition: an "action of an organism's effector. An effector is an organ at the end of an efferent nerve fiber that is specialized for altering its environment mechanically, chemically, or in terms of other energy changes" (Michael, 2004, p. 8). (See also **response class.**)

response blocking A procedure in which the therapist physically intervenes as soon as the learner begins to emit a problem behavior, to prevent completion of the targeted behavior.

response class A group of responses of varying topography, all of which produce the same effect on the environment.

response cost The response-contingent loss of a specific number of positive reinforcers (e.g., a fine) that decreases the frequency of similar responses in the future; a form of negative punishment.

response differentiation A behavior change produced by differential reinforcement: Reinforced members of the current response class occur with greater frequency, and unreinforced members occur less frequently (undergo extinction); the overall result is the emergence of a new response class.

response generalization The extent to which a learner emits untrained responses that are functionally equivalent to the trained target behavior. (Compare to **response maintenance** and **setting/situation generalization.**)

response interruption and redirection (RIRD) A procedural variation of response blocking that involves interrupting stereotypic behavior at its onset and redirecting the individual to complete high-probability behaviors instead.

response latency A measure of temporal locus; the elapsed time from the onset of a stimulus (e.g., task direction, cue) to the initiation of a response.

response maintenance The extent to which a learner continues to perform the target behavior after a portion or all of the intervention responsible for the behavior's initial appearance in the learner's repertoire has been terminated. (Often called *maintenance, durability, behavioral persistence*, and (incorrectly) *resistance to extinction*; compare to **response generalization** and **setting/situation generalization.**)

response prompts Prompts that operate directly on the response to cue a correct response. The three major forms of response prompts are verbal instructions, modeling, and physical guidance.

response-deprivation hypothesis A model for predicting whether contingent access to one behavior will function as reinforcement for engaging in another behavior based on whether access to the contingent behavior represents a restriction of the activity compared to the baseline level of engagement. (See also **Premack principle.**)

restitutional overcorrection A form of overcorrection in which, contingent on the problem behavior, the learner is required to repair the damage or return the environment to its original state and then to engage in additional behavior

to bring the environment to a condition vastly better than it was in prior to the misbehavior. (See also **overcorrection** and **positive practice overcorrection.**)

restraint Three common types of restraint—personal restraint, protective equipment restraint, and self-restraint—appear in the behavior analysis literature. With *personal restraint*, therapists physically restrict the problem behavior by holding the body parts (e.g., response blocking) that produce the problem behavior. With *protective equipment restraints*, therapists often use protective equipment restraints (e.g., padded helmets, arm splints, boxing gloves, padded hand mitts, safety belts, safety straps) to protect individuals from causing serious injury. Persons with self-injurious behavior (SIB) often apply *self-restraint*, such as sitting on hands, placing arms between folded legs, and wrapping arms in tight clothing.

resurgence Refers to the reoccurrence of a previously reinforced behavior when reinforcement for an alternative behavior is terminated or decreased and to the three-phase procedure that produces the effect: (1) A target behavior is reinforced, (2) the target behavior is placed on extinction and reinforcement provided for an alternative behavior, and (3) both responses are placed on extinction.

reversal design Any experimental design in which the researcher attempts to verify the effect of the independent variable by "reversing" responding to a level obtained in a previous condition; encompasses experimental designs in which the independent variable is withdrawn (A-B-A-B) or reversed in its focus (e.g., DRI/DRA). (See also **A-B-A design, A-B-A-B design, B-A-B design, DRI/DRA reversal technique, DRO reversal technique,** and **noncontingent reinforcement [NCR] reversal technique.**)

risk–benefit analysis A comparison prior to conducting a behavioral assessment or intervention of the potential harm to the client (or others) versus the benefits likely to result from the procedures.

rule-governed behavior Behavior controlled by a rule (i.e., a verbal statement of an antecedent-behavior-consequence contingency); enables human behavior (e.g., fastening a seat belt) to come under the indirect control of temporally remote or improbable, but potentially significant consequences (e.g., avoiding injury in an auto accident). Often used in contrast to *contingency-shaped behavior*, a term used to indicate behavior selected and maintained by controlled, temporally close consequences.

S

satiation A decrease in the frequency of operant behavior presumed to be the result of continued contact with or consumption of a reinforcer that has followed the behavior; also refers to a procedure for reducing the effectiveness of a reinforcer (e.g., presenting a person with copious amounts of a reinforcing stimulus prior to a session). (See also **motivating operation;** contrast with **deprivation.**)

scatterplot A two-dimensional graph that shows the relative distribution of individual measures in a data set with respect to the variables depicted by the *x*- and *y*-axes. Data points on a scatterplot are not connected.

scatterplot recording A procedure for recording the extent to which a target behavior occurs more often at particular times than others; involves dividing the day into blocks of time, and using different symbols on an observation form to indicate the level of the target behavior (e.g., a lot, some, or not at all).

schedule of reinforcement A rule specifying the environmental arrangements and response requirements for reinforcement; a description of a contingency of reinforcement.

schedule thinning Changing a contingency of reinforcement by gradually increasing the response ratio or the extent of the time interval; it results in a lower rate of reinforcement per responses, time, or both.

science A systematic approach to the understanding of natural phenomena (as evidenced by description, prediction, and control) that relies on determinism as its fundamental assumption, empiricism as its primary rule, experimentation as its basic strategy, replication as a requirement for believability, parsimony as a value, and philosophic doubt as its guiding conscience.

scored-interval IOA An interobserver agreement index based only on the intervals in which either observer recorded the occurrence of the behavior; calculated by dividing the number of intervals in which the two observers agreed that the behavior occurred by the number of intervals in which either or both observers recorded the occurrence of the behavior and multiplying by 100. Scored-interval IOA is recommended as a measure of agreement for behaviors that occur at low rates because it ignores the intervals in which agreement by chance is highly likely. (Compare to **interval-by-interval IOA** and **unscored-interval IOA.**)

selection by consequences The fundamental principle underlying operant conditioning; the basic tenet is that all forms of (operant) behavior, from simple to complex, are selected, shaped, and maintained by their consequences during an individual's lifetime; Skinner's concept of selection by consequences is parallel to Darwin's concept of natural selection of genetic structures in the evolution of species.

selection-based verbal behavior A category of verbal behavior in which the speaker points to or selects a particular stimulus; what is conveyed to the listener is the information on the stimulus selected. (Contrast with **topography-based verbal behavior**)

selectionism A theory that all forms of life naturally and continually evolve as a result of the interaction between function and the survival value of that function. Operant selection by consequences is the conceptual and empirical foundation of behavior analysis.

self-contract Contingency contract that a person makes with himself or herself, incorporating a self-selected task and reward as well as personal monitoring of task completions and self-delivery of the reward.

self-control [impulse analysis] A person's ability to "delay gratification" by emitting a response that will produce a larger (or higher quality) delayed reward over a response that produces a smaller but immediate reward. (Sometimes called *impulse control.*)

self-control [Skinner's analysis] Skinner (1953) conceptualized self-control as a two-response phenomenon: The *controlling response* affects variables in such a way as to change the probability of the *controlled response*. (See also **self-management.**)

self-evaluation A procedure in which a person compares her performance of a target behavior with a predetermined goal or standard; often a component of self-management. (Sometimes called *self-assessment.*)

self-instruction Self-generated verbal responses, covert or overt, that function as rules or response prompts for a desired behavior; as a self-management tactic, self-instruction can guide a person through a behavior chain or sequence of tasks.

self-management The personal application of behavior change tactics that produces a desired change in behavior.

self-monitoring A procedure whereby a person systematically observes his behavior and records the occurrence or nonoccurrence of a target behavior. (Also called *self-recording* or *self-observation.*)

semilogarithmic chart A two-dimensional graph with a logarithmic scaled *y* axis so that equal distances on the vertical axis represent changes in behavior that are of equal proportion. (See also **Standard Celeration Chart.**)

sensory extinction A procedure by which behaviors maintained by automatic reinforcement are placed on extinction by masking or removing the sensory consequence.

sequence effects The effects on a subject's behavior in a given condition that are the result of the subject's experience with a prior condition.

setting/situation generalization The extent to which a learner emits the target behavior in a setting or stimulus situation that is different from the instructional setting.

shaping Using differential reinforcement to produce a series of gradually changing response classes; each response class is a successive approximation toward a terminal behavior. Members of an existing response class are selected for differential reinforcement because they more closely resemble the terminal behavior. (See also **differential reinforcement, response class, response differentiation,** and **successive approximations.**)

simple discrimination Responding is under stimulus control of a single antecedent stimulus condition; described by the three-term contingency: $S^D \rightarrow R \rightarrow S^{R+}$.

simple verbal discrimination A single-component word or phrase evokes a nonmatching intraverbal response (e.g., upon hearing "Ready, set . . . ," a child says "go,")

simple-to-complex testing protocol An arrangement in which types of stimulus equivalence probes are introduced sequentially, beginning with symmetry, followed by transitivity (if relevant), and then combined tests for equivalence.

single-case designs A wide variety of research designs that use a form of experimental reasoning called *baseline logic* to demonstrate the effects of the independent variable on the behavior of individual subjects. (Also called *single-subject, within-subject*, and *intra-subject* designs; see also **baseline logic, changing criterion design, multielement design, multiple baseline design, reversal design,** and **steady state strategy.**)

social validity Refers to the extent to which target behaviors are appropriate, intervention procedures are acceptable, and important and significant changes in target and collateral behaviors are produced.

socially mediated contingency (reinforcement) A contingency in which an antecedent stimulus and/or the consequence for the behavior is presented by another person.

solistic (tact) extension A verbal response evoked by a stimulus property that is only indirectly related to the proper tact relation (e.g., Yogi Berra's classic malapropism: "Baseball is ninety percent mental; the other half is physical."

spaced-responding DRL A procedure for implementing DRL in which reinforcement follows each occurrence of the target behavior that is separated from the previous response by a minimum interresponse time (IRT). (See also **differential reinforcement of low rates [DRL].**)

spatial relation Responding jointly to two stimuli on the basis of their juxtaposition in space.

speaker Someone who engages in verbal behavior by emitting mands, tacts, intraverbals, autoclitics, etc. A speaker is also someone who uses sign language, gestures, signals, written words, codes, pictures, or any form of verbal behavior. (Contrast with **listener.**)

split-middle line of progress A line drawn through a series of graphed data points that shows the overall trend in the data; drawn through the intersections of the vertical and horizontal middles of each half of the charted data and then adjusted up or down so that half of all the data points fall on or above and half fall on or below the line.

spontaneous recovery A behavioral effect associated with extinction in which the behavior suddenly begins to occur after its frequency has decreased to its prereinforcement level or stopped entirely.

stable baseline Data that show no evidence of an upward or downward trend; all of the measures fall within a relatively small range of values. (See also **steady state responding.**)

Standard Celeration Chart A multiply–divide chart with six base-10 (or × 10, ÷ 10) cycles on the vertical axis that can accommodate response rates as low as 1 per 24 hours (0.000695 per minute) to as high as 1000 per minute. It enables the standardized charting of celeration, a factor by which rate of behavior multiplies or divides per unit of time. (See also **semilogarithmic chart.**)

steady state responding A pattern of responding that exhibits relatively little variation in its measured dimensional quantities over a period of time.

steady state strategy Repeatedly exposing a subject to a given condition while trying to eliminate or control extraneous influences on the behavior and obtaining a stable pattern of responding before introducing the next condition.

stimulus "An energy change that affects an organism through its receptor cells" (Michael, 2004, p. 7).

stimulus blocking Occurs when a competing stimulus blocks the evocative function of a stimulus that has acquired stimulus control over the behavior. (Sometimes called *masking*.) Stimulus blocking can be mitigated by rearranging the physical environment, making instructional stimuli appropriately intense, and consistently reinforcing behavior in the presence of the instructionally relevant discriminative stimuli.

stimulus class A group of stimuli that share specified common elements along formal (e.g., size, color), temporal (e.g., antecedent or consequent), and/or functional (e.g., discriminative stimulus) dimensions.

stimulus control A situation in which the frequency, latency, duration, or amplitude of a behavior is altered by the presence or absence of an antecedent stimulus. (See also **discrimination** and **discriminative stimulus.**)

stimulus delta (S^{Δ}) A stimulus in the presence of which a given behavior has not produced reinforcement, or has produced reinforcement of lesser quality, in the past. (Contrast with **discriminative stimulus [S^D].**)

stimulus discrimination When one stimulus (the S^D) signals the availability of reinforcement and the absence of that stimulus (the S^{Δ}) signals a zero or reduced chance of reinforcement, responses will occur more often in the presence of the S^D than in its absence (the S^{Δ}).

stimulus discrimination training The conventional procedure requires one behavior and two antecedent stimulus conditions. Responses are reinforced in the presence of one stimulus condition, the S^D, but not in the presence of the other stimulus, the S^{Δ}.

stimulus equivalence The emergence of accurate responding to untrained and nonreinforced stimulus–stimulus relations following the reinforcement of responses to some stimulus–stimulus relations. Requires successful performances on three types of probe trials—reflexivity, symmetry, and transitivity—in the absence of reinforcement. (Also called *equivalence-class formation*.)

stimulus fading A method of transferring stimulus control that involves highlighting a physical dimension of a stimulus (e.g., size, color, position) to increase the likelihood of a correct response and then gradually diminishing the exaggerated dimension until the learner is responding correctly to the naturally occurring stimulus.

stimulus generalization When an antecedent stimulus has a history of evoking a response that has been reinforced in its presence, the same type of behavior tends to be evoked by stimuli that share similar physical properties with the controlling antecedent stimulus.

stimulus generalization gradient A graphic depiction of the extent to which behavior that has been reinforced in the presence of a specific stimulus condition is emitted in the presence of other stimuli. The gradient shows relative degrees of stimulus generalization and stimulus control (or discrimination). A flat slope across test stimuli shows a high degree of stimulus generalization and relatively little discrimination between the trained stimulus and other stimuli; a slope that drops sharply from its highest point corresponding to the trained stimulus indicates a high degree of stimulus control (discrimination) and relatively little stimulus generalization.

stimulus preference assessment A variety of procedures used to determine the stimuli that a person prefers, the relative preference values (high versus low) of those stimuli, the conditions under which those preference values remain in effect, and their presumed value as reinforcers.

stimulus prompts Prompts that operate directly on the antecedent task stimuli to cue a correct response in conjunction with the critical S^D (e.g., changing the size, color, or position of a stimulus within an array to make its selection more likely).

stimulus–control topographies Refers to two different forms of stimulus control that can result from a match-to-sample procedure involving one sample stimulus and two comparison stimuli; when presented with A1 as the sample, a participant can either *select* B1 (known as *Type S* or *select responding*) or *reject* B2 (known as *Type R* or *reject responding*).

stimulus–stimulus pairing A procedure in which two stimuli are presented at the same time, usually repeatedly for a number of trials, which often results in one stimulus acquiring the function of the other stimulus.

successive approximations The sequence of new response classes that emerge during the shaping process as the result of differential reinforcement; each successive response class is closer in form to the terminal behavior than the response class it replaces.

surrogate conditioned motivating operation (CMO-S) A stimulus that acquires its MO effectiveness by being paired with another MO and has the same value-altering and behavior-altering effects as the MO with which it was paired.

symmetry A type of stimulus-to-stimulus relationship in which the learner, without prior training or reinforcement for doing so, demonstrates the reversibility of matched sample and comparison stimuli (e.g., if A = B, then B = A). Symmetry would be demonstrated in the following matching-to-sample procedure: The learner is taught, when presented with the spoken word *car* (sample stimulus A), to select a comparison picture of a car (comparison B).

When presented with the picture of a car (sample stimulus B), without additional training or reinforcement, the learner selects the comparison spoken word *car* (comparison A). (See also **stimulus equivalence**; compare to **reflexivity** and **transitivity.**)

systematic desensitization A behavior therapy treatment for anxieties, fears, and phobias that involves substituting one response, generally muscle relaxation, for the unwanted behavior—the fear and anxiety. The client practices relaxing while imagining anxiety-producing situations in a sequence from the least fearful to the most fearful.

systematic replication An experiment in which the researcher purposefully varies one or more aspects of an earlier experiment. A systematic replication that reproduces the results of previous research not only demonstrates the reliability of the earlier findings but also adds to the external validity of the earlier findings by showing that the same effect can be obtained under different conditions.

T

tact An elementary verbal operant involving a response that is evoked by a nonverbal discriminative stimulus and followed by generalized conditioned reinforcement. Tacting allows a speaker to identify or describe the features of the physical environment. The elements that make up one's physical environment are vast; thus, much of language instruction and educational programs focus on teaching tacts.

tact extension Once a tact has been established, the tact response can occur under novel stimulus conditions through the process of stimulus generalization. Skinner (1957) identifies four different levels of generalization based on the degree to which a novel stimulus shares the relevant or defining features of the original stimulus. The four types of tact extension are generic, metaphorical, metonymical, and solecistic.

taking dictation An elementary verbal operant involving a spoken verbal stimulus that evokes a written, typed, or fingerspelled response that does not have formal similarity between the stimulus and the response, but does have point-to-point correspondence and a history of generalized reinforcement.

tandem schedule (tand) A schedule of reinforcement identical to the chained schedule except, like the mix schedule, the tandem schedule does not use discriminative stimuli with the elements in the chain. (See also **chained schedule** and **mixed schedule.**)

target behavior The response class selected for intervention; can be defined either functionally or topographically.

task analysis The process of breaking a complex skill or series of behaviors into smaller, teachable units; also refers to the results of this process.

teach loosely Randomly varying functionally irrelevant stimuli within and across teaching sessions; promotes setting/situation generalization by reducing the likelihood that (a) a single or small group of noncritical stimuli will acquire exclusive control over the target behavior and (2) the learner's performance of the target behavior will be impeded or "thrown off" should he encounter any of the "loose" stimuli in the generalization setting.

teach enough examples A strategy for promoting generalized behavior change that consists of teaching the learner to respond to a subset of all the relevant stimulus and response examples and then assessing the learner's performance on untrained examples. (See also **multiple exemplar training.**)

temporal extent Refers to the fact that every instance of behavior occurs during some amount of time; one of the three dimensional quantities of behavior from which all behavioral measurements are derived. (See also **repeatability** and **temporal locus.**)

temporal locus Refers to the fact that every instance of behavior occurs at a certain point in time with respect to other events (i.e., when in time behavior occurs can be measured); often measured in terms of *response latency* and *interresponse time (IRT)*; one of the three dimensional quantities of behavior from which all behavioral measurements are derived. (See also **repeatability** and **temporal extent.**)

temporal relation Responding jointly to two stimuli on the basis of their juxtaposition in time.

terminal behavior The end product of shaping.

terminate specific reinforcer contact A variation of nonexclusion time-out whereby each occurrence of the target behavior immediately stops an activity or sensory reinforcer.

textual An elementary verbal operant involving a response that is evoked by a written verbal discriminative stimulus that does not have formal similarity between the stimulus and the response, but does have point-to-point correspondence and a history of generalized reinforcement.

three-term contingency The basic unit of analysis in the analysis of operant behavior; encompasses the temporal and possibly dependent relations among an antecedent stimulus, behavior, and consequence.

time delay A procedure for transferring stimulus control from contrived response prompts to naturally existing stimuli that begins with the simultaneous presentation of the natural stimulus and response prompt. After several correct responses, a delay is introduced between the stimulus and the response prompt until the student emits the unprompted correct response. Time delay is considered an "errorless learning" technique as students make few or no errors transitioning from the contrived prompt to the instructional stimulus. (See also **constant time delay** and **progressive time delay.**)

time sampling A measurement of the presence or absence of behavior within specific time intervals. It is most useful with continuous and high-rate behaviors. (See also **momentary time sampling, partial-interval recording,** and **whole-interval recording.**)

time-out from positive reinforcement The immediate response-contingent withdrawal of the opportunity to earn positive reinforcement or the immediate loss of access to positive reinforcers for a specified time; a form of negative punishment. (Also called *time-out.*)

token An object or symbol that is awarded contingent on appropriate target behavior(s) that can be traded for a wide variety of backup reinforcers; tokens function as generalized conditioned reinforcers.

token economy A behavior change system consisting of a list of target behaviors, with tokens (points or small objects) participants earn for emitting the target behaviors, and a menu of backup reinforcers (i.e., preferred items, activities, or privileges) for which participants exchange earned tokens. (Also called *token reinforcement system.*)

topography The physical form or shape of a behavior.

topography-based definition Defines instances of the targeted response class by the shape or form of the behavior.

topography-based verbal behavior A category of verbal behavior in which the listener is affected by a specific response topography emitted by the speaker; includes (e.g., speech, sign language, writing, fingerspelling). (Contrast with **selection-based verbal behavior**)

total count IOA The simplest indicator of IOA for event recording data; based on comparing the total count recorded by each observer per measurement period; calculated by dividing the smaller of the two observers' counts by the larger count and multiplying by 100.

total duration IOA A relevant index of IOA for total duration measurement; computed by dividing the shorter of the two durations reported by the observers by the longer duration and multiplying by 100.

total-task chaining A variation of forward chaining in which the learner receives training on each behavior in the chain during each session.

training structure Refers to dimensions of procedural arrangements when teaching multiple conditional discriminations. Commonly used training structures include *one-to-many training* or *sample-as-node training*, *many-to-one* or *comparison-as-node structure*, and *linear series training*.

transcription An elementary verbal operant involving a spoken verbal stimulus that evokes a written, typed, or finger-spelled response. Like the textual, there is point-to-point correspondence between the stimulus and the response product, but no formal similarity.

transfer of function Occurs when teaching a new function for one member of an established equivalence class results in the same function holding for all members of the class.

transformation of function Occurs when the behavioral function of one stimulus in a stimulus class changes as a predictable function of the behavior function of other stimuli in the class.

transitive conditioned motivating operation (CMO-T) An environmental variable that, as a result of a learning history, establishes (or abolishes) the reinforcing effectiveness of another stimulus and evokes (or abates) the behavior that has been reinforced by that other stimulus.

transitivity Describes derived stimulus–stimulus relations (e.g., A = C) that emerge as a product of training two other stimulus–stimulus relations (A = B and B = C). Transitivity would be demonstrated if, after training, the following occurs: (1) If A (e.g., spoken word *bicycle*) = B (e.g., the picture of a bicycle) and (2) B (the picture of a bicycle) = C (e.g., the written word *bicycle*), then (3) A (the spoken name, *bicycle*) = C (the written word *bicycle*). (See also **stimulus equivalence;** compare to **reflexivity** and **symmetry**).

treatment drift An undesirable situation in which the independent variable of an experiment is applied differently during later stages than it was at the outset of the study.

treatment integrity The extent to which the independent variable is applied exactly as planned and described and no other unplanned variables are administered inadvertently along with the planned treatment. (Contrast with **procedural fidelity.**)

treatment package A behavioral intervention consisting of multiple components (e.g., contingent praise, tokens, and extinction).

trend The overall direction taken by a data path. It is described in terms of direction (increasing, decreasing, or zero trend), degree (gradual or steep), and the extent of variability of data points around the trend. Trend is used in predicting future measures of the behavior under unchanging conditions.

trial-based functional analysis An analysis in which a series of trials is interspersed among classroom activities. Each trial consists of two 1-minute components: (a) the establishing operation and contingency for problem behavior (test condition), and (b) continuous access to the reinforcer (control condition).

trial-by-trial IOA An IOA index for discrete trial data based on comparing the observers' counts (0 or 1) on a trial-by-trial, or item-by-item, basis; yields a more conservative and meaningful index of IOA for discrete trial data than does total count IOA.

true value A measure accepted as a quantitative description of the true state of some dimensional quantity of an event as it exists in nature. Obtaining true values requires "special or extraordinary precautions to ensure that all possible sources of error have been avoided or removed" (Johnston & Pennypacker, 1993a, p. 136). (Compare to **observed value.**)

trials-to-criterion A special form of event recording; a measure of the number of responses or practice opportunities needed for a person to achieve a pre-established level of accuracy or proficiency.

Type I error An error that occurs when a researcher concludes that the independent variable had an effect on the dependent variable, when no such relation exists; a *false positive*. (Contrast with **Type II error.**)

Type II error An error that occurs when a researcher concludes that the independent variable had no effect on the dependent variable, when in truth it did; a *false negative*. (Contrast with **Type I error.**)

U

unchaining Occurs when, in the case of a two-step chain, the second behavior in the chain (R_2) produces reinforcement in the presence of the prior S^D (S_2), but (R_2) also produces reinforcement when that S^D is not present. Unchaining may weaken a chain.

unconditioned motivating operation (UMO) A motivating operation whose value-altering effect does not depend on a learning history. For example, food deprivation increases the reinforcing effectiveness of food without the necessity of any learning history.

unconditioned negative reinforcer A stimulus that functions as a negative reinforcer as a result of the evolutionary development of the species (phylogeny); no prior learning is involved (e.g., shock, loud noise, intense light, extreme temperatures, strong pressure against the body). (See also **negative reinforcer;** compare to **conditioned negative reinforcer.**)

unconditioned punisher A stimulus change that decreases the frequency of any behavior that immediately precedes it irrespective of the organism's learning history with the stimulus. Unconditioned punishers are products of the evolutionary development of the species (phylogeny), meaning that all members of a species are more or less susceptible to punishment by the presentation of unconditioned punishers. (Also called *primary* or *unlearned punishers*; compare to **conditioned punisher.**)

unconditioned reflex An unlearned stimulus–response functional relation consisting of an antecedent stimulus (e.g., food in mouth) that elicits the response (e.g., salivation); a product of the phylogenic evolution of a given species; all biologically intact members of a species are born with similar repertoires of unconditioned reflexes. (See also **conditioned reflex.**)

unconditioned reinforcer A stimulus change that increases the frequency of any behavior that immediately precedes it irrespective of the organism's learning history with the stimulus. Unconditioned reinforcers are the product of the evolutionary development of the species (phylogeny). (Also called *primary* or *unlearned reinforcer*; compare to **conditioned reinforcer.**)

unconditioned stimulus (US) The stimulus component of an unconditioned reflex; a stimulus change that elicits respondent behavior without any prior learning.

unpairing Two kinds: (a) The occurrence alone of a stimulus that acquired its function by being paired with an already effective stimulus, or (b) the occurrence of the stimulus in the absence as well as in the presence of the effective stimulus. Both kinds of unpairing undo the result of the pairing: the occurrence alone of the stimulus that became a conditioned reinforcer; and the occurrence of the unconditioned reinforcer in the absence as well as in the presence of the conditioned reinforcer.

unscored-interval IOA An interobserver agreement index based only on the intervals in which either observer recorded the nonoccurrence of the behavior; calculated by dividing the number of intervals in which the two observers agreed that the behavior did not occur by the number of intervals in which either or both observers recorded the nonoccurrence of the behavior and multiplying by 100. Unscored-interval IOA is recommended as a measure of agreement for behaviors that occur at high rates because it ignores the intervals in which agreement by chance is highly likely. (Compare to **interval-by-interval IOA** and **scored-interval IOA.**)

V

validity (of measurement) The extent to which data obtained from measurement are directly relevant to the target behavior of interest and to the reason(s) for measuring it.

value-altering effect (of a motivating operation) Either (a) an increase in the reinforcing effectiveness of some stimulus, object, or event, in which case the MO is an establishing operation (EO); or (b) a decrease in reinforcing effectiveness, in which case the MO is an abolishing operation (AO). For example, the reinforcing effectiveness of food is altered as a result of food deprivation and food ingestion.

variability The frequency and extent to which multiple measures of behavior yield different outcomes.

variable baseline Data points that do not consistently fall within a narrow range of values and do not suggest any clear trend.

variable interval (VI) A schedule of reinforcement that provides reinforcement for the first correct response following the elapse of variable durations of time occurring in a random or unpredictable order. The mean duration of the intervals is used to describe the schedule (e.g., on a VI 10-min schedule, reinforcement is delivered for the first response following an average of 10 minutes since the last reinforced response, but the time that elapses following the last reinforced response might range from 30 seconds or less to 25 minutes or more).

variable ratio (VR) A schedule of reinforcement requiring a varying number of responses for reinforcement. The number of responses required varies around a random number; the mean number of responses required for reinforcement is used to describe the schedule (e.g., on a VR 10 schedule an

average of 10 responses must be emitted for reinforcement, but the number of responses required following the last reinforced response might range from 1 to 30 or more).

variable-interval DRO (VI-DRO) A DRO procedure in which reinforcement is available at the end of intervals of variable duration and delivered contingent on the absence of the problem behavior during the interval. (See also **differential reinforcement of other behavior [DRO].**)

variable-momentary DRO (VM-DRO) A DRO procedure in which reinforcement is available at specific moments of time, which are separated by variable amounts of time in random sequence, and delivered if the problem is not occurring at those times. (See **also differential reinforcement of other behavior [DRO].**)

variable-time schedule (VT) A schedule for the delivery of noncontingent stimuli in which the interval of time from one delivery to the next randomly varies around a given time. For example, on a VT 1-min schedule, the delivery-to-delivery interval might range from 5 seconds to 2 minutes, but the average interval would be 1 minute.

verbal behavior Behavior whose reinforcement is mediated by a listener; includes both vocal-verbal behavior (e.g., saying "*Water, please*" to get water) and nonvocal-verbal behavior (pointing to a glass of water to get water). Encompasses the subject matter usually treated as language and topics such as thinking, grammar, composition, and understanding.

verbal conditional discrimination (VC^D) A type of convergent multiple control involving a verbal stimulus that alters the evocative effects of another verbal stimulus in the same antecedent configuration. The conditional discrimination is between the words in the antecedent event.

verbal episode An interaction between a speaker and a listener. A speaker emits any type of verbal response (e.g., echoic, mand, tact, intraverbal), in any form (speech, sign language, icon selection, eye contact), and a listener (1) serves as an audience for a speaker, (2) provides reinforcement for a speaker, and (3) responds in specific ways to the speaker's behavior. The roles of speaker and listener switch back and forth in an exchange, and usually involve covert speaker and listener behavior as well.

verbal function-altering effect Verbal stimuli can alter the functional effects of immediate or future SD s and MOs and, accordingly, change a listener's behavior. For example, being told "The bridge is out, turn left at the 7-Eleven and there will be another one in 5 miles" can alter the functional effects of stimuli encountered in the future and evoke verbal and nonverbal behavior at that time (e.g., tacting the 7-Eleven, turning left).

verification One of three components of the experimental reasoning, or baseline logic, used in single-subject research designs; accomplished by demonstrating that the prior level of baseline responding would have remained unchanged had the independent variable not been introduced. Verifying the accuracy of the original prediction reduces the probability that some uncontrolled (confounding) variable was responsible for the observed change in behavior. (See also **prediction** and **replication.**)

video modeling A behavior change strategy in which the participant views a video of a model performing the target behavior and then imitates the behavior.

video self-modeling A behavior change strategy in which the participant views a video of himself successfully performing the target behavior and then imitates his own model.

visual analysis A systematic approach for interpreting the results of behavioral research and treatment programs that entails visual inspection of graphed data for level, trend, and variability within and between experimental conditions.

W

whole-interval recording A time sampling method for measuring behavior in which the observation period is divided into a series of brief time intervals (typically from 5 to 15 seconds). At the end of each interval, the observer records whether the target behavior occurred throughout the entire interval; tends to underestimate the overall percentage of the observation period in which the target behavior actually occurred.

withdrawal design A term used by some authors as a synonym for A-B-A-B design; also used to describe experiments in which an effective treatment is sequentially or partially withdrawn to promote the maintenance of behavior changes. (See also **A-B-A-B design** and **reversal design.**)

GLOBAL EDITION

This is a special edition of an established title widely used by colleges and universities throughout the world. Pearson published this exclusive edition for the benefit of students outside the United States and Canada. If you purchased this book within the United States or Canada, you should be aware that it has been imported without the approval of the Publisher or Author.

Applied Behavior Analysis equips students with a sound repertoire of fundamental knowledge about this field that serves as the foundation for more advanced study. The third edition of this pioneering text continues to illustrate behavior analysis principles and procedures with actual applications and real data, helping students acquire the conceptual and technical skills necessary to foster socially adaptive behavior in diverse individuals. The book consists of seven chapters authored by prominent scholars who first reported some of the most significant advances in behavior analysis in publications such as the *Journal of Applied Behavior Analysis, The Analysis of Verbal Behavior*, and the *Journal of the Experimental Analysis of Behavior.*

In addition to updated content and the latest research, this edition includes the following:

- Two new chapters, by noted scholars, on equivalence-based instruction and non-equivalence relations (Chapters 19 and 20) build upon ground-breaking research in the field of applied behavior analysis.
- Multiple-choice and essay-type questions at the end of each chapter test students' mastery of the concepts they have learned.
- Over 2,700 citations and extensive use of quotations and extracts from key publications increase students' exposure to and appreciation for the field's rich primary-source literature.
- More than 150 graphs display original data from peer-reviewed research, often accompanied by detailed descriptions of the procedures used to collect the data represented, helping students develop and refine higher-level visual analysis skills.
- Over 500 technical terms and concepts in the glossary help students finesse the specialized vocabulary of applied behavior analysis.
